The external force at A is in immediate equilibrio with the combined forces, connecting A with D and with C. AI is one of them, therefore AK is the other; and AL is the compound force with which the external force at A is in immediate equilibrium. This external force is therefore equal and opposite to AL. In like manner, the external force at B is equal and opposite to BO; and AL is to BO as the external force at A to the external force at B. The prop C resists with forces equal to those which are propagated to it from the points D, A, and C. Therefore it resists with forces CH, CG, equal and opposite to DG, DH; and it resists the compressions KA, NB, with equal and opposite forces C*k*, C*n*. Draw *kl*, *no*, parallel to AD, BD, and draw C*l*Q, C*o*P: It is plain that *k*CH*l* is a parallelogram equal to KAIL, and that C*l* is equal to AL. In like manner C*o* is equal to BO. Now the forces C*k*, CH, exerted by the prop, compose the force C*l*; and C*n*, CG, compose the force C*o*. These two forces C*l*, C*o*, are equal and parallel to AL and BO; and therefore they are equal and opposite to the external forces acting at A and B. But they are, primitively, equal and opposite to the pressures, or at least the compounds of the pressures, exerted on the prop, by the forces propagated to C from A, D, and B. Therefore the pressures exerted on the prop are the same as if the external forces were applied there in the same directions as they are applied to A and B. Now if we make C*v*, C*z*, equal to C*l* and C*o*, and complete the parallelogram C*vyz*, it is plain that the force *y*C is in equilibrio with *l*C and *o*C. Therefore the pressures at A, C, and B are such as would balance if applied to one point.

Lastly, in order to determine their proportions, draw CS and CR perpendicular to DA and DB. Also draw A*d*, B*f*, perpendicular to CQ and CP; and draw C*g*, C*i*, perpendicular to AE, BF.

The triangles CPR and BP*f* are similar, having a common angle P, and a right angle at R and *f*.

In like manner, the triangles CQS and AQ*d* are similar. Also the triangles CHR, CGS, are similar, by reason of the equal angles at H and G, and the right angles at R and S. Hence we obtain the following analogies:

$$\begin{aligned} Co : CP &= on : PB, = CG : PB \\ CP : CR &= \qquad PB : fB \\ CR : CS &= \qquad CH : CG \\ CS : CQ &= \qquad Ad : AQ \\ CQ : Cl &= AQ : hl, = AQ : CH. \end{aligned}$$

Therefore, by equality,

$$\begin{aligned} Co : Cl &= \qquad Ad : fB \\ \text{or } BO : AL &= \qquad Cg : Ci. \end{aligned}$$

That is, the external forces are reciprocally proportional to the perpendiculars drawn from the prop on the lines of their direction.[1]

Extensive consequences.

This proposition, sufficiently general for our purpose, is fertile in consequences, and furnishes many useful instructions to the artist. The strains LA, OB, CY, that are excited, occur in many, we may say in all, framings of carpentry, whether for edifices or engines, and are the sources of their efficacy. It is also evident that the doctrine of the transverse strength of timber is contained in this proposition; for every piece of timber may be considered as an assemblage of parts, connected by forces which act in the direction of the lines which joined the strained points on the matter which lies between those points, and also act on the rest of the matter, exciting those lateral forces which produce the inflexibility of the whole. See Strength of Materials.

Thus it appears that this proposition contains the principles which direct the artist to frame the most powerful levers; to secure uprights by shores or braces, or by tiers and ropes; to secure scaffoldings for the erection of spires; and many other more delicate problems of his art. He also learns from this proposition how to ascertain the strains that are produced, without his intention, by pieces which he intended for other offices, and which, by their transverse action, puts his work in hazard. In short, this proposition is the key to the science of this art.

We would now counsel the artist, after he has made the tracing of the strains and thrusts through the various parts of a frame familiar to his mind, and even amused himself with some complicated fancy framings, to read over with care the articles Strength of Materials and Roof. He will now conceive its doctrine much more clearly than when he was considering them as abstract theories. The mutual action of the woody fibres will now

---

[1] "The learned reader will perceive that this analogy is precisely the same with that of forces which are in equilibrio by the intervention of a lever. In fact, this whole frame of carpentry is nothing else than a *built* or *framed lever* in equilibrio. It is acting in the same manner as a solid, which occupies the whole figure compressed in the frame, or as a body of any size and shape whatever that will admit the three points of application A, C, and B. It is always in equilibrio in the case first stated; because the pressure *produced* at B by a force applied to A is always such as balances it. The reader may also perceive, in this proposition, the analysis or tracing of those internal mechanical forces which are indispensably requisite for the functions of a lever. The mechanicians have been extremely puzzled to find a legitimate demonstration of the equilibrium of a lever ever since the days of Archimedes. Mr Vince has the honour of first demonstrating, most ingeniously, the principle assumed by Archimedes, but without sufficient ground for *his* demonstration; but Mr Vince's demonstration is only a putting the mind into that perplexed state which makes it acknowledge the proposition, but without a clear perception of its truth. The difficulty has proceeded from the abstract notion of a lever, conceiving it as a mathematical line—inflexible, without reflecting how it is inflexible; for the very source of this indispensable quality furnishes the mechanical connection between the remote pressures and the fulcrum; and this supplies the demonstration (without the least difficulty) of the desperate case of a straight lever urged by parallel forces." See the article Rotation.

Carpentry. be easily comprehended, and his confidence in the results will be greatly increased.

Decision of a disputed and very important question. There is a proposition (see article Roof) which has been called in question by several very intelligent persons; and they say that Belidor has demonstrated, in his *Science des Ingenieurs*, that a beam firmly fixed at both ends is not twice as strong as when simply lying on the props; and that its strength is increased only in the proportion of two to three; and they support this determination by a list of experiments recited by Belidor, which agree *precisely* with it. Belidor also says that Pitot had the same result in his experiments. These are respectable authorities, but Belidor's reasoning is any thing but demonstration, and his experiments are described in such an imperfect manner that we cannot build much on them. It is not said in what manner the battens were secured at the ends, any further than that it was by *chevalets*. If by this word is meant a trestle, we cannot conceive how they were employed; but we see it sometimes used for a wedge or key. If the battens were wedged in the holes, their resistance to fracture may be made what we please; they may be made loose, and therefore resist little more than when simply laid on props. They may be (and probably were) wedged very fast, and bruised or crippled.

Our proposition mentioned distinctly the security given to the ends of the beams. They were mortised into remote posts. Our *precise* meaning was, that they were simply kept from rising by these mortises, but at full liberty to bend up at E and I, and between G and K. Our assertion was not made from theory alone (although we think the reasoning incontrovertible), but was agreeable to numerous experiments made in those precise circumstances. Had we mortised the beams firmly into two very stout posts which could not be drawn nearer to each other by bending, the beam would have borne a *much* greater weight, as we have verified by experiments. We hope that the following mode of conceiving this case will remove all doubts.

Let LM be a long beam (fig. 14) divided into six equal parts, in the points D, B, A, C, E. Let it be firmly supported at L, B, C, M. Let it be cut through at A, and have compass joints at B and C. Let FB, GC, be two equal uprights, resting on B and C, but without any connection. Let AH be a similar and equal piece, to be occasionally applied at the seam A. Now let a thread or wire AGE be extended over the piece GC, and made fast at A, G, and E. Let the same thing be done on the other side of A. If a weight be now laid on at A, the wires AFD, AGE, will be strained, and may be broken. In the instant of fracture we may suppose their strains to be represented by Af and Ag. Complete the parallelogram, and Aa is the magnitude of the weight. It is plain that nothing is concerned here but the cohesion of the wires; for the beam is sawed through at A, and its parts are perfectly movable round B and C.

Instead of this process, apply the piece AH below A, and keep it there by straining the same wire BHC over it. Now lay on a weight. It must press down the ends of BA and CA, and cause the piece AH to strain the wire BHC. In the instant of fracture of *the same* wire, its resistances Hb and Hc must be equal to Af and Ag, and the weight hH which breaks them must be equal to Aa.

Lastly, employ all the three pieces FB, AH, GC, with the same wire attached as before. There can be no doubt but that the weight which breaks all the four wires must be $= a\text{A} + h\text{H}$, or twice Aa.

The reader cannot but see that the wires perform the very same office with the fibres of an entire beam LM held fast in the four holes D, B, C, and E, of some upright posts.

In the experiments for verifying this, by breaking slender bars of fine deal, we get complete demonstration, by measuring the curvatures produced in the parts of the beam thus held down, and comparing them with the curvature of a beam simply laid on the props B and C; and there are many curious inferences to be made from these observations, but we have not room for them in this place.

The best manner of framing purlins. We may observe by the way, that we learn from this case that purlins are able to carry twice the load when notched into the rafters that they carry when mortised into them, which is the most usual manner of framing them. So would the bending joists of floors; but this would double the thickness of the flooring. But this method should be followed in every possible case, such as brest summers, lintels over several pillars, &c. These should never be cut off and mortised into the sides of every upright; numberless cases will occur which show the importance of the maxim.

We must here remark, that the proportion of the spaces BC and CM, or BC and LB, has a very sensible effect on the strength of the beam BC; but we have not yet satisfied our minds as to the *rationale* of this effect. It is undoubtedly connected with the serpentine form of the curve of the beam before fracture. This should be attended to in the construction of the springs of carriages. These are frequently supported at the middle point (and it is an excellent practice); and there is a certain proportion which will give the easiest motion to the body of the carriage. We also think that it is connected with that deviation from the best theory observable in Buffon's experiments on various lengths of the same scantling. The force of the beams diminished much more than in the inverse proportion of their lengths.

In what case ties are better than struts. We have seen that it depends entirely on the position of the pieces in respect of their points of ultimate support, and of the direction of the external force which produces the strains, whether any particular piece is in a state of extension or of compression. The knowledge of this circumstance may greatly influence us in the choice of the construction. In many cases we may substitute slender iron rods for massive beams, when the piece is to act the part of a tie. But we must not invert this disposition; for when a piece of timber acts as a strut, and is in a state of compression, it is next to certain that it is not equally compressible in its opposite sides through the whole length of the piece, and that the compressing force on the abutting joint is not acting in the most equable manner all over the joint. A very trifling inequality in either of these circumstances (especially in the first) will compress the beam more on one side than on the other. This cannot be without the beam's bending, and becoming concave on that side on which it is most compressed. When this happens, the frame is in danger of being crushed, and soon going to ruin. It is, therefore, indispensably necessary to make use of beams in all cases where struts are required of considerable length, rather than of metal rods of slender dimensions, unless in situations where we can effectually prevent their bending, as in trussing a girder internally, where a cast-iron strut may be firmly cased in it, so as not to bend in the smallest degree. In cases where the pressures are enormous, as in the very oblique struts of a centre or arch frame, we must be particularly cautious to do nothing which can facilitate the compression of either side. No mortises should be cut near to one side; no lateral pressures, even the slightest, should be allowed to touch it. We have seen a pillar of fir twelve inches long, and one inch in section, when loaded with three tons, snap in an instant when pressed on one side by sixteen pounds, while another bore four and a half tons without hurt, because it was inclosed (loosely) in a stout pipe of iron. (See Note DD.)

In such cases of enormous compression it is of great importance that the compressing force bear equally on the whole abutting surface. The German carpenters are accustomed to put a plate of lead over the joint. This prevents, in some measure, the penetration of the end fibres. M. Perronet, the celebrated French architect, formed his abutments into arches of circles, the centre of which was the remote end of the strut. By this contrivance the unavoidable change of form of the triangle made no partial bearing of either angle of the abutment. This always has a tendency to splinter off the heel of the beam where it presses strongest. It is a very judicious practice. (See Note EE.)

When circumstances allow it, we must rather employ ties than struts for securing a beam against lateral strains. When an upright pillar, such as a flag-staff, a mast, or the uprights of a very tall scaffolding, are to be shoared up, the dependence is more certain on those braces that are stretched by the strain than on those which are compressed. The scaffolding of the iron bridge near Sunderland had some ties very judiciously disposed, and others with less judgment.

We should proceed to consider the transverse strains as they affect the various parts of a frame of carpentry; but we have very little to say here in addition to what will be found in the articles Strength of Materials and Roof. What we shall add in this article will find a place in our occasional remarks on different works. It may, however, be of use to recal to the reader's memory the following propositions.

General theorems concerning the relative strength of beams.

1. When a beam AB (fig. 15) is firmly fixed at the end A, and a straining force acts perpendicularly to its length at any point B, the strain occasioned at any section C between B and A is proportional to CB, and may therefore be represented by the product $w \times$ CB; that is, by the product of the number of tons, pounds, &c. which measure the straining force, and the number of feet, inches, &c. contained in CB. As the loads on a beam are easily conceived, we shall substitute this for any other straining force.

2. If the strain or load is uniformly distributed along any part of the beam lying beyond C (that is, farther from A), the strain at C is the same as if the load were all collected at the middle point of that part; for that point is the centre of gravity of the load.

3. The strain on any section D of a beam AB (fig. 16) resting freely on two props A and B, is $w \times \frac{\text{AD} \times \text{DB}}{\text{AB}}$. (See Roof, No. 19, and Strength of Materials, No. 92, &c.) Therefore,

4. The strain on the middle point, by a force applied there, is one fourth of the strain which the same force would produce if applied to one end of a beam of the same length having the other end fixed.

5. The strain on any section C of a beam, resting on two props A and B, occasioned by a force applied perpendicularly to another point D, is proportional to the rectangle of the exterior segments, or is equal to $w \times \frac{\text{AC} \times \text{DB}}{\text{AB}}$. Therefore,

The strain at C occasioned by the pressure on D is the same with the strain at D occasioned by the same pressure on C.

6. The strain on any section D, occasioned by a load uniformly diffused over any part EF, is the same as if the two parts ED, DF, of the load were collected at their middle points e and f. Therefore,

The strain on any part D, occasioned by a load uniformly distributed over the whole beam, is one half of the strain that is produced when the same load is laid on at D; and

The strain on the middle point C, occasioned by a load uniformly distributed over the whole beam, is the same which half that load would produce if laid on at C.

7. A beam supported at both ends on two props B and C (fig. 14), will carry twice as much when the ends beyond the props are kept from rising, as it will carry when it rests loosely on the props.

8. Lastly, the transverse strain on any section, occasioned by a force applied obliquely, is diminished in the proportion of the sine of the angle which the direction of the force makes with the beam. Thus, if it be inclined to it in an angle of thirty degrees, the strain is one half of the strain occasioned by the same force acting perpendicularly.

On the other hand, the relative strength of a beam, or its power in any particular section to resist any transverse strain, is proportional to the absolute cohesion to the section directly, to the distance of its centre of effort from the axis of fracture directly, and to the distance from the strained point inversely.

Thus, in a rectangular section of the beam, of which b is the breadth, d the depth (that is, the dimension in the direction of the straining force), measured in inches, and f the number of pounds which one square inch will just support without being torn asunder, we must have $f \times b \times d^2$, proportional to $w \times$ CB (fig. 15). Or, $f \times b \times d^2$, multiplied by some number m, depending on the nature of the timber, must be equal to $w \times$ CB. Or, in the case of the section C of fig. 16, that is strained by the force w applied at D, we must have $m \times fbd^2 = w \times \frac{\text{AC} \times \text{DB}}{\text{AB}}$. Thus, if the beam is of sound oak, m is very nearly $= \frac{1}{9}$ (see Strength of Materials, No. 116.) Therefore we have $\frac{fbd^2}{9} = w \times \frac{\text{AC} \times \text{CB}}{\text{AB}}$. (See Note FF.)

Hence we can tell the precise force w which any section C can just resist when that force is applied in any way whatever; for the above-mentioned formula gives $w = \frac{fbd^2}{9\text{CB}}$ for the case represented by fig. 15. But the case represented in fig. 16, having the straining force applied at D, gives the strain at C $(= w) = f \times \frac{bd^2 \times \text{AB}}{9\text{AC} \times \text{CB}}$.

Example. Let an oak beam, four inches square, rest freely on the props A and B, seven feet apart, or eighty-four inches. What weight will it just support at its middle point C, on the supposition that a square inch rod will just carry 16,000 pounds, pulling it asunder?

The formula becomes $w = \frac{16000 \times 4 \times 16 \times 84}{9 \times 42 \times 42}$, or $w = \frac{86016000}{15876}$, $= 5418$ pounds. This is very near what was employed in Buffon's experiment, which was 5312.

Had the straining force acted on a point D, half way between C and B, the force sufficient to break the beam at C would be $= \frac{16000 \times 4 \times 16 \times 84}{9 \times 42 \times 21} = 10836$ lbs.

Had the beam been sound red fir, we must have taken $f = 10{,}000$ nearly, and m nearly 8; for although fir be less cohesive than oak in the proportion of five to eight nearly, it is less compressible, and its axis of fracture is therefore nearer to the concave side.

Of joints.

Having considered at sufficient length the strains of different kinds which arise from the form of the parts of a frame of carpentry, and the direction of the external forces which act on it, whether considered as impelling or as supporting its different parts, we must now proceed to con-

sider the means by which this form is to be secured, and the connections by which those strains are excited and communicated.

The joinings practised in carpentry are almost infinitely various, and each has advantages which make it preferable in some circumstances. Many varieties are employed merely to please the eye. We do not concern ourselves with these: nor shall we consider those which are only employed in connecting small works, and can never appear on a great scale; yet even in some of these, the skill of the carpenter may be discovered by his choice; for in all cases, it is wise to make every, even the smallest, part of his work as strong as the materials will admit. He will be particularly attentive to the changes which will necessarily happen by the shrinking of timber as it dries, and will consider what dimensions of his framings will be affected by this, and what will not; and will then dispose the pieces which are less essential to the strength of the whole, in such a manner that their tendency to shrink shall be in the same direction with the shrinking of the whole framing. If he do otherwise, the seams will widen, and parts will be split asunder. He will dispose his boardings in such a manner as to contribute to the stiffness of the whole, avoiding at the same time the giving them positions which will produce lateral strains on truss beams which bear great pressures; recollecting, that although a single board has little force, yet many united have a great deal, and may frequently perform the office of very powerful struts.

Our limits confine us to the joinings which are most essential for connecting the parts of a single piece of a frame when it cannot be formed of one beam, either for want of the necessary thickness or length; and the joints for connecting the different sides of a trussed frame.

Of building up beams.

Much ingenuity and contrivance has been bestowed on the manner of building up a great beam of many thicknesses, and many singular methods are practised as great nostrums by different artists; but when we consider the manner in which the cohesion of the fibres performs its office, we will clearly see that the simplest are equally effected with the most refined, and that they are less apt to lead us into false notions of the strength of the assemblage.

Building up a girder or lever.

Joggling preferable to scarfing.

Thus, were it required to build up a beam for a great lever or a girder, so that it may act nearly as a beam of the same size of one log, it may either be done by plain joggling, as in Plate CLXI. fig. 17, A, or by scarfing, as in fig. 17, B or C. If it is to act as a lever, having the gudgeon on the lower side at C, we believe that most artists will prefer the form B and C; at least this has been the case with nine tenths of those to whom we have proposed the question. The best informed only hesitated; but the ordinary artists were all confident in its superiority, and we found their views of the matter very coincident. They considered the upper piece as grasping the lower in its hooks; and several imagined, that by driving the one very tight on the other, the beam would be stronger than an entire log; but if we attend carefully to the internal procedure in the loaded lever, we shall find the upper one clearly the strongest. If they are formed of equal logs, the upper one is thicker than the other by the depth of the joggling or scarfing, which we suppose to be the same in both; consequently, if the cohesion of the fibres in the intervals is able to bring the uppermost filaments into full action, the form A is stronger than B, in the proportion of the greater distance of the upper filaments from the axis of the fracture. This may be greater than the difference of the thickness if the wood is very compressible. If the gudgeon be in the middle, the effect, both of the joggles and the scarfings, is considerably diminished; and if it is on the upper side the scarfings act in a very different way. In this situation, if the loads on the arms are also applied to the upper side, the joggled beam is still more superior to the scarfed one. This will be best understood by resolving it in imagination into a trussed frame. But when a gudgeon is thus put on that side of the lever which grows convex by the strain, it is usual to connect it with the rest by a powerful strap, which embraces the beam, and causes the opposite point to become the resisting point. This greatly changes the internal actions of the filaments, and in some measure brings it into the same state as the first, with the gudgeon below. Were it possible to have the gudgeon on the upper side, and to bring the whole into action without a strap, it would be the strongest of all; because in general the resistance to compression is greater than to extension. In every situation the joggled beam has the advantage, and it is the easiest executed. (See Note GG.)

We may frequently gain a considerable accession of strength by this building up of a beam, especially if the part which is stretched by the strain be of oak, and the other part be fir. Fir being so much superior to oak as a pillar (if Muschenbroeck's experiments may be confided in), and oak so much preferable as a tie, this construction seems to unite both advantages. But we shall see much better methods of making powerful levers, girders, &c. by trussing.

Observe that the efficacy of both methods depends entirely on the difficulty of causing the piece between the cross joints to slide along the timber to which it adheres. Therefore, if this be moderate, it is wrong to make the notches deep; for as soon as they are so deep that their ends have a force sufficient to push the slice along the line of junction, nothing is gained by making them deeper; and this requires a greater expenditure of timber.

Scarfings are frequently made oblique, as in fig. 18; but we imagine that this is a bad practice. It begins to yield at a point where the wood is crippled and splintered off, or at least bruised out a little. As the pressure increases, this part, by squeezing broader, causes the solid parts to rise a little upwards, and gives them some tendency, not only to push their antagonists along the base, but even to tear them up a little. For similar reasons, we disapprove of the favourite practice of many artists to make the angles of their scarfings acute, as in fig. 19. This often causes the two pieces to tear each other up The abutments should always be perpendicular to the directions of the pressures. Lest it should be forgotten in its proper place, we may extend this injunction also to the abutments of different pieces of a frame, and recommend it to the artist even to attend to the shrinking of the timbers by drying. When two timbers abut obliquely, the joint should be most full at the obtuse angle of the end; because, by drying, that angle grows more obtuse, and the beam would then be in danger of splintering off at the acute angle.

We must not wedge too hard.

It is evident that the nicest work is indispensably necessary in building up a beam. The parts must abut on each other completely, and the smallest play or void takes away the whole efficacy. It is usual to give the butting joints a small taper to one side of the beam, so that they may require moderate blows of a maul to force them in; and the joints may be perfectly close when the external surfaces are even on each side of the beam. But we must not exceed in the least degree, for a very taper wedge has great force; and if we have driven the pieces together by very heavy blows, we leave the whole in a state of violent strain, and the abutments are perhaps ready to splinter off by a small addition of pressure. This is like too severe a proof for artillery; which, though not sufficient to burst the pieces, has weakened them to such a

Carpentry.

degree, that the strain of ordinary service is sufficient to complete the fracture. The *workman* is tempted to exceed in this, because it smooths off and conceals all uneven seams; but he must be watched. It is not unusual to leave some abutments open enough to admit a thin wedge reaching through the beam. Nor is this a bad practice, if the wedge is of material which is not compressed by the driving or the strain of service. Iron would be preferable for this purpose, and for the joggles, were it not that, by its too great hardness, it cripples the fibres of timber to some distance. In consequence of this it often happens, that in beams which are subjected to desultory and sudden strains (as in the levers of reciprocating engines), the joggles or wedges widen the holes, and work themselves loose; therefore skilful engineers never admit them, and indeed as few bolts as possible, for the same reason; but when resisting a steady or dead pull, they are not so improper, and are frequently used.

Beams are built up, not only to increase their dimensions in the direction of the strain (which we have hitherto called their depth), but also to increase their breadth, or the dimensions perpendicular to the strain. We sometimes double the breadth of a girder which is thought too weak for its load, and where we must not increase the thickness of the flooring.

Building of masts.

The mast of a great ship of war must be made bigger athwartship, as well as fore and aft. This is one of the nicest problems of the art; and professional men are by no means agreed in their opinions about it. We do not presume to decide, and shall content ourselves with exhibiting the different methods.

The most obvious and natural method is that shown in fig. 20. It is plain that (independent of the connection of cross bolts, which are used in them all when the beams are square) the piece C cannot bend in the direction of the plane of the figure without bending the piece D along with it. This method is much used in the French navy; but it is undoubtedly imperfect. Hardly any two great trees are of equal quality, and swell or shrink alike. If C shrinks more than D, the feather of C becomes loose in the groove wrought in D to receive it; and when the beam bends, the parts can slide on each other like the plates of a coach-spring; and if the bending is in the direction *cf*, there is nothing to hinder this sliding but the bolts, which soon work themselves loose in the bolt-holes.

Method used in the French navy.

Another method.

Fig. 21 exhibits another method. The two halves of the beam are tabled into each other in the same manner as in fig. 17. It is plain that this will not be affected by the unequal swelling or shrinking, because this is insensible in the direction of the fibres; but when bent in the direction *ab*, the beam is weaker than fig. 20 bent in the direction *cf*. Each half of fig. 20 has, in every part of its length, a thickness greater than half the thickness of the beam. It is the contrary in the alternate portions of the halves of fig. 21. When one of them is bent in the direction AB, it is plain that it drags the other with it by means of the cross butments of its tables, and there can be no longitudinal sliding. But unless the work is accurately executed, and each hollow completely filled up by the table of the other piece, there will be a lateral slide along the cross joints sufficient to compensate for the curvature; and this will hinder the one from compressing or stretching the other in conformity to this curvature.

Its imperfection.

The imperfection of this method is so obvious that it has seldom been practised; but it has been combined with the other, as is represented in fig. 22, where the beams are divided along the middle, and the tables in each half are alternate, and alternate also with the tables of the other half. Thus 1, 3, 4, are prominent, and 5, 2, 6, are depressed. This construction evidently puts a stop to both slides, and obliges every part of both pieces to move together. *ab* and *cd* show sections of the built-up beam corresponding to AB and CD.

No more is intended in this practice by any intelligent artist, than the causing the two pieces to act together in all their parts, although the strains may be unequally distributed on them. Thus, in a built-up girder, the binding joists are frequently mortised into very different parts of the two sides. But many seem to aim at making the beam stronger than if it were of one piece; and this inconsiderate project has given rise to many whimsical modes of tabling and scarfing, which we need not regard.

British method.

The practice in the British dock-yards is somewhat different from any of these methods. The pieces are tabled as in fig. 22, but the tables are not thin parallelopipeds, but thin prisms. The two outward joints or visible seams are straight lines, and the table No. 1 rises gradually to its greatest thickness in the axis. In like manner, the hollow, 5, for receiving the opposite table, sinks gradually from the edge to its greatest depth in the axis. Fig. 23, No. 1, represents a section of a round piece of timber built up in this way, where the full line EFGH is the section corresponding to AB of fig. 22, and the dotted line EGFH is the section corresponding to CD.

This construction, by making the external seam straight, leaves no lodgment for water, and looks much fairer to the eye; but it appears to us that it does not give so firm a hold when the mast is bent in the direction EH. The exterior parts are most stretched and most compressed by this bending; but there is hardly any abutment in the exterior parts of these tables. In the very axis, where the abutment is the firmest, there is little or no difference of extension and compression.

But this construction has an advantage, which, we imagine, much more than compensates for these imperfections, at least in the particular case of a round mast; it will draw together by hooping incomparably better than any of the others. If the cavity be made somewhat too shallow for the prominence of the tables, and if this be done uniformly along the whole length, it will make a somewhat open seam; and this opening can be regulated with the utmost exactness from end to end by the plane. The heart of those vast trunks is very sensibly softer than the exterior circles; therefore, when the whole is hooped, and the hoops hard driven, and at considerable intervals between each spell, we are confident that all may be compressed till the seam disappears; and then the whole makes one piece, *much* stronger than if it were an original log of that size, because the middle has become, by compression, as solid as the crust, which was naturally firmer, and resisted farther compression. We verified this beyond a doubt by hooping a built stick of a timber which has this inequality of firmness in a remarkable degree, and it was nearly twice as strong as another of the same size.

Our mast-makers are not without their fancies and whims; and the manner in which our masts and yards are generally built up is not near so simple as fig. 23; but it consists of the same essential parts, acting in the very same manner, and derives all its efficacy from the principles which are here employed.

Attended with peculiar advantages.

This construction is particularly suited to the situation and office of a ship's mast. It has no bolts; or, at least, none of any magnitude, or that make very important parts of its construction. The most violent strains perhaps that it is exposed to, is that of twisting, when the lower yards are close braced up by the force of many men acting by a long lever. This form resists a twist with peculiar energy; it is therefore an excellent method for building up a great shaft for a mill. The way in which they are usually built up is by reducing a central log to a poly-

Carpentry. gonal prism, and then filling it up to the intended size by *planting* pieces of timber along its sides, either spiking them down, or cocking them into it by a feather, or joggling them by slips of hard wood sunk into the central log and into the slips. *N.B.* Joggles of elm are sometimes used in the middle of the large tables of masts; and when sunk into the firm wood near the surface, they must contribute much to the strength. But it is very necessary to employ wood not much harder than the pine, otherwise it will soon enlarge its bed, and become loose, for the timber of these large trunks is very soft.

The most general reason for piecing a beam is to increase its length. This is frequently necessary, in order to procure tie-beams for very wide roofs. Two pieces must be scarfed together. Numberless are the modes of doing this, and almost every master carpenter has his favourite nostrum. Some of them are very ingenious; but here, as in other cases, the most simple are commonly the strongest. We do not imagine that any, the most ingenious, is equally strong with a tie consisting of two pieces of the same scantling laid over each other for a certain length, and firmly bolted together. We acknowledge that this will appear an artless and clumsy tie-beam, but we only say that it will be stronger than any that is more artificially made up of the same thickness of timber. This, we imagine, will appear sufficiently certain.

Various methods of scarfing.

The simplest and most obvious scarfing, after the one now mentioned, is that represented in fig. 24, No. 1 and 2. If considered merely as two pieces of wood joined, it is plain that, as a tie, it has but half the strength of an entire piece, supposing that the bolts (which are the only connections) are fast in their holes. No. 2 requires a bolt in the middle of the scarf to give it that strength, and in every other part is weaker on one side or the other. (See Note HH.)

But the bolts are very apt to bend by the violent strain, and require to be strengthened by uniting their ends by iron plates; in which case it is no longer a wooden tie. The form of No. 1 is better adapted to the office of a pillar than No. 2, especially if its ends be formed in the manner shown in the elevation No. 3. By the sally given to the ends, the scarf resists an effort to bend it in that direction. Besides, the form of No. 2 is unsuitable for a post; because the pieces, by sliding on each other by the pressure, are apt to splinter off the tongue which confines their extremity.

Fig. 25 and 26 exhibit the most approved form of a scarf, whether for a tie or for a post. The key represented in the middle is not essentially necessary; the two pieces might simply meet square there. This form, without a key, needs no bolts (although they strengthen it greatly); but, if worked very true and close, and with square abutments, will hold together, and will resist bending in any direction. But the key is an ingenious and a very great improvement, and will force the parts together with perfect tightness. The same precaution must be observed that we mentioned on another occasion, not to produce a constant internal strain on the parts by overdriving the key. The form of fig. 25 is by far the best; because the triangle of 26 is much easier splintered off by the strain, or by the key, than the square wood of 25. It is far preferable for a post, for the reason given when speaking of fig. 24, No. 1 and No. 2. Both may be formed with a sally at the ends equal to the breadth of the key. In this shape fig. 25 is vastly well suited for joining the parts of the long corner posts of spires and other wooden towers. Fig. 25, No. 2, differs from No. 1 only by having three keys. The principal and the longitudinal strength are the same. The long scarf of No. 2, tightened by the three keys, enables it to resist a bending much better.

None of these scarfed tie-beams can have more than one third of the strength of an entire piece, unless with the assistance of iron plates; for if the key be made thinner than one third, it has less than one third of the fibres to pull by. Carpentry.

We are confident, therefore, that when the heads of the bolts are connected by plates, the simple form of fig. 24, No. 1, is stronger than those more ingenious scarfings. It may be strengthened against lateral bending by a little tongue, or by a sally, but cannot have both.

The strongest of all methods of piecing a tie-beam would be to set the parts end to end, and grasp them between other pieces on each side, as in fig. 27, Plate CLXII. This is what the ship-carpenter calls *fishing* a beam, and is a frequent practice for occasional repairs. M. Perronet used it for the tie-beams or stretchers, by which he connected the opposite feet of a centre, which was yielding to its load, and had pushed aside one of the piers above four inches. Six of these not only withstood a strain of 1800 tons, but, by wedging behind them, he brought the feet of the truss 2½ inches nearer. The stretchers were 14 inches by 11 of sound oak, and could have withstood three times that strain. M. Perronet, fearing that the great length of the bolts employed to connect the beams of these stretchers would expose them to the risk of bending, scarfed the two side pieces into the middle piece. The scarfing was of the triangular kind (*Trait de Jupiter*), and only an inch deep, each face being two feet long, and the bolt passed through close to the angle.

Fishing a beam.

In piecing the pump-rods and other wooden stretchers of great engines, no dependence is had on scarfing; and the engineer connects every thing by iron straps. We doubt the propriety of this, at least in cases where the bulk of the wooden connection is not inconvenient. These observations must suffice for the methods employed for connecting the parts of a beam; and we now proceed to consider what are more usually called the joints of a piece of carpentry.

Square joints.

Where the beams stand square with each other, and the strains are also square with the beams, and in the plane of the frame, the common mortise and tenon is the most perfect junction. A pin is generally put through both, in order to keep the pieces united, in opposition to any force which tends to part them. Every carpenter knows how to bore the hole for this pin, so that it shall draw the tenon tight into the mortise, and cause the shoulder to butt close, and make neat work; and he knows the risk of tearing out the bit of the tenon beyond the pin, if he draw it too much. We may just observe, that square holes and pins are much preferable to round ones for this purpose, bringing more of the wood into action, with less tendency to split it. The ship-carpenters have an ingenious method of making long wooden bolts, which do not pass completely through, take a very fast hold, though not nicely fitted to their holes, which they must not be, lest they should be crippled in driving. They call it *fox-tail wedging*. They stick into the point of the bolt a very thin wedge of hard wood, so as to project a proper distance; when this reaches the bottom of the hole by driving the bolt, it splits the end of it, and squeezes it hard to the side. This may be practised with advantage in carpentry. If the ends of the mortise are widened inwards, and a thin wedge be put into the end of the tenon, it will have the same effect, and make the joint equal to a dove-tail. But this risks the splitting the piece beyond the shoulder of the tenon, which would be unsightly. This may be avoided as follows: Let the tenon T, fig. 28, have two *very* thin wedges *a* and *c* struck in near its angles, projecting equally; at a very small distance within these, put in two shorter ones *b*, *d*, and more within these if necessary. In driving this tenon,

Fox-tail wedging.

the wedges *a* and *c* will take first, and split off a thin slice, which will easily bend without breaking. The wedges *b*, *d*, will act next, and have a similar effect, and the others in succession. The thickness of all the wedges taken together must be equal to the enlargement of the mortise towards the bottom.

When the strain is transverse to the plane of the two beams, the principles laid down in No. 85, 86, of the article STRENGTH OF MATERIALS, will direct the artist in placing his mortise. Thus the mortise in a girder for receiving the tenon of a binding joist of a floor should be as near the upper side as possible, because the girder becomes concave on that side by the strain. But as this exposes the tenon of the binding-joist to the risk of being torn off, we are obliged to mortise farther down. The form (fig. 29) generally given to this joint is extremely judicious. The sloping part *a b* gives a very firm support to the additional bearing *e d*, without much weakening of the girder. This form should be copied in every case where the strain has a similar direction.

Oblique mortise and tenon.

The joint that most of all demands the careful attention of the artist, is that which connects the ends of beams, one of which pushes the other very obliquely, putting it into a state of extension. The most familiar instance of this is the foot of a rafter pressing on the tie-beam, and thereby *drawing* it away from the other wall. When the direction is very oblique (in which case the extending strain is the greatest), it is difficult to give the foot of the rafter such a hold of the tie-beam as to bring many of its fibres into the proper action. There would be little difficulty if we could allow the end of the tie-beam to project to a small distance beyond the foot of the rafter; but, indeed, the dimensions which are given to tie-beams for other reasons, are always sufficient to give enough of abutment when judiciously employed. Unfortunately this joint is much exposed to failure by the effects of the weather. It is much exposed, and frequently perishes by rot, or becomes so soft and friable that a very small force is sufficient either for pulling the filaments out of the tie-beam, or for crushing them together. We are therefore obliged to secure it with particular attention, and to avail ourselves of every circumstance of construction.

One is naturally disposed to give the rafter a deep hold by a long tenon; but it has been frequently observed in old roofs that such tenons break off. Frequently they are observed to tear up the wood that is above them, and push their way through the end of the tie-beam. This in all probability arises from the first sagging of the roof, by the compression of the rafters and of the head of the king-post. The head of the rafter descends; the angle with the tie-beam is diminished by the rafter revolving round its step in the tie-beam. By this motion the heel or inner angle of the rafter becomes a fulcrum to a very long and powerful lever much loaded. The tenon is the other arm, very short; and being still fresh, it is therefore very powerful. It therefore forces up the wood that is above it, tearing it out from between the cheeks of the mortise, and then pushes it along. Carpenters have therefore given up long tenons, and give to the toe of the tenon a shape which abuts firmly, in the direction of the thrust, on the solid bottom of the mortise, which is well supported on the under side by the wall-plate. This form has the further advantage of having no tendency to tear up the end of the mortise. This form is represented in fig. 30. The tenon has a small portion *ab* cut perpendicular to the surface of the tie-beam, and the rest *bc* is perpendicular to the rafter. (See Note CC.)

But if the tenon is not sufficiently strong (and it is not so strong as the rafter, which is thought not to be stronger than is necessary), it will be crushed, and then the rafter will shade out along the surface of the beam. It is therefore necessary to call in the assistance of the whole rafter. It is in this distribution of the strain among the various abutting parts that the varieties of joints and their merits chiefly consist. It would be endless to describe every nostrum, and we shall only mention a few that are most generally approved of.

Most approved forms

The aim in fig. 31 is to make the abutments exactly perpendicular to the thrusts. (See Note CC.) It does this very precisely; and the share which the tenon and the shoulder have of the whole may be what we please, by the portion of the beam that we notch down. If the wall-plate lie duly before the heel of the rafter, there is no risk of straining the tie across or breaking it, because the thrust is made to direct to that point where the beam is supported. The action is the same as against the joggle on the head or foot of a king-post. We have no doubt but that this is a very effectual joint. It is not, however, much practised. It is said that the sloping seam at the shoulder lodges water; but the great reason seems to be a secret notion that it weakens the tie-beam. If we consider the direction in which it acts as a tie, we must acknowledge that this form takes the best method for bringing the whole of it into action.

Fig. 32 exhibits a form that is more general, but certainly worse. Such part of the thrust as is not borne by the tenon acts obliquely on the joint of the shoulder, and gives the whole a tendency to rise up and slide outward.

The shoulder joint is sometimes formed like the dotted line *abedcfg* of fig. 32. This is much more agreeable to the true principle, and would be a very perfect method, were it not that the intervals *bd* and *df* are so short that the little wooden triangles *bed*, *dcf*, will be easily pushed off their bases *bd*, *df*.

Fig. 33, No. 1, seems to have the most general approbation. It is the joint recommended by Price, and copied into all books of carpentry as the *true joint* for a rafter foot. The visible shoulder-joint is flush with the upper surface of the tie-beam. The angle of the tenon at the tie nearly bisects the obtuse angle formed by the rafter and the beam, and is therefore somewhat oblique to the thrust. The inner shoulder *ac* is nearly perpendicular to *bd*. The lower angle of the tenon is cut off horizontally, as at *ed*. Fig. 34 is a section of the beam and rafter foot, showing the different shoulders.

We do not perceive the peculiar merit of this joint. The effect of the three oblique abutments, *ab*, *ac*, *ed*, is undoubtedly to make the whole bear on the outer end of the mortise, and there is no other part of the tie-beam that makes immediate resistance. Its only advantage over a tenon extending in the direction of the thrust is, that it will not tear up the wood above it. Had the inner shoulder had the form *eci*, having its face *ic* perpendicular, it would certainly have acted more powerfully in stretching many filaments of the tie-beam, and would have had much less tendency to force out the end of the mortise. The little bit *ci* would have prevented the sliding upwards along *ec*. At any rate, the joint *ab* being flush with the beam, prevents any sensible abutment on the shoulder *ac*.

Fig. 33, No. 2, is a simpler, and in our opinion a preferable, joint. We observe it practised by the most eminent carpenters for all oblique thrusts; but it surely employs less of the cohesion of the tie-beam than might be used without weakening it, at least when it is supported on the other side by the wall-plate.

Fig. 33, No. 3, is also much practised by the first carpenters.

Fig. 35, No. 1, is proposed by Mr Nicholson as preferable to fig. 33, No. 3, because the abutment of the inner

Carpentry. part is better supported. This is certainly the case; but it supposes the whole rafter to go to the bottom of the socket, and the beam to be thicker than the rafter. Some may think that this will weaken the beam too much, when it is no broader than the rafter is thick; in which case they think that it requires a deeper socket than Nicholson has given it. Perhaps the advantages of Nicholson's construction may be had by a joint like fig. 35, No. 2.

Circumstance to be attended to.

Whatever is the form of these butting joints, great care should be taken that all parts bear alike; and the artist will attend to the magnitude of the different surfaces. In the general compression, the greater surfaces will be less compressed, and the smaller will therefore change most. When all has settled, every part should be *equally* close. Because great logs are moved with difficulty, it is very troublesome to try the joint frequently to see how the parts fit; therefore we must expect less accuracy in the interior parts. This should make us prefer those joints whose efficacy depends chiefly on the visible joint.

It appears from all that we have said on this subject, that a very small part of the cohesion of the tie-beam is sufficient for withstanding the horizontal thrust of a roof, even though very low pitched. If therefore no other use is made of the tie-beam, one much slenderer may be used, and blocks may be firmly fixed to the ends, on which the rafters might abut, as they do on the joggles on the head and foot of a king-post. Although a tie-beam has commonly floors or ceilings to carry, and sometimes the workshops and store-rooms of a theatre, and therefore requires a great scantling, yet there frequently occur in machines and engines very oblique stretchers, which have no other office, and are generally made of dimensions quite inadequate to their situation, often containing ten times the necessary quantity of timber. It is therefore of importance to ascertain the most perfect manner of executing such a joint. We have directed the attention to the principles that are really concerned in the effect. In all hazardous cases, the carpenter calls in the assistance of iron straps; and they are frequently necessary, even in roofs, notwithstanding this superabundant strength of the tie-beam. But this is generally owing to bad construction of the wooden joint, or to the failure of it by time. Straps will be considered in their place.

There needs but little to be said of the joints at a joggle worked out of solid timber; they are not near so difficult as the last. When the size of a log will allow the joggle to receive the whole breadth of the abutting brace, it ought certainly to be made with a square shoulder; or, which is still better, an arch of a circle, having the other end of the brace for its centre. (See Note EE.) Indeed this in general will not sensibly differ from a straight line perpendicular to the brace. By this circular form, the settling of the roof makes no change in the abutment; but when there is not sufficient stuff for this, we must avoid bevel joints at the shoulders, because these always tend to make the brace slide off. The brace in fig. 36, No. 1, must not be joined as at *b*, but as at *a*, or in some equivalent manner. Observe the joints at the head of the main posts of Drury Lane theatre, fig. 44, Plate CLXIV.

Butting joints.

When the very oblique action of one side of a frame of carpentry does not extend, but compress, the piece on which it abuts (as in fig. 11), there is no difficulty in the joint. Indeed a joining is unnecessary, and it is enough that the pieces abut on each other; and we have only to take care that the mutual pressure be equally borne by all the parts, and that it do not produce lateral pressures, which may cause one of the pieces to slide on the butting joint. A very slight mortise and tenon is sufficient at the joggle of a king-post with a rafter or straining beam. It is best, in general, to make the butting plain, bisecting the angle formed by the sides, or else perpendicular to one of the pieces. In fig. 36, No. 2, where the straining beam, *ab*, cannot slip away from the pressure, the joint *a* is preferable to *b*, or indeed to any uneven joint, which never fails to produce very unequal pressures on the different parts, by which some are crippled, others are splintered off, &c. Carpentry.

Directions for placing iron straps.

When it is necessary to employ iron straps for strengthening a joint, considerable attention is necessary, that we may place them properly. The first thing to be determined is the direction of the strain. This is learned by the observations in the beginning of this article. We must then resolve this strain into a strain parallel to each piece, and another perpendicular to it. Then the strap which is to be made fast to any of the pieces must be so fixed that it shall resist in the direction parallel to the piece. Frequently this cannot be done; but we must come as near to it as we can. In such cases we must suppose that the assemblage yields a little to the pressures which act on it. We must examine what change of shape a small yielding will produce. We must now see how this will affect the iron strap which we have already supposed attached to the joint in some manner that we thought suitable. This settling will perhaps draw the pieces away from it, leaving it loose and unserviceable (this frequently happens to the plates which are put to secure the obtuse angles of butting timbers, when their bolts are at some distance from the angles, especially when these plates are laid on the inside of the angles); or it may cause it to compress the pieces harder than before, in which case it is answering our intention. But it may be producing cross strains, which may break them, or it may be crippling them. We can hardly give any general rules; but the reader will do well to read what is written in No. 36 and 41 of the article ROOF. In No. 36 he will see the nature of the strap or stirrup, by which the king-post carries the tie-beam. The strap that we observe most generally ill placed is that which connects the foot of the rafter with the beam. It only binds down the rafter, but does not act against its horizontal thrust. It should be placed farther back on the beam, with a bolt through it, which will allow it to turn round. It should embrace the rafter almost horizontally near the foot, and should be notched square with the back of the rafter. Such a construction is represented in fig. 37. By moving round the eye-bolt, it follows the rafter, and cannot pinch and cripple it, which it always does in its ordinary form. We are of opinion that straps which have eye-bolts in the very angles, and allow all motion round them, are of all the most perfect. A branched strap, such as may at once bind the king-post and the two braces which butt on its foot, will be more serviceable if it have a joint. When a roof warps, those branched straps frequently break the tenons, by affording a fulcrum in one of their bolts. An attentive and judicious artist will consider how the beams will act on such occasions, and will avoid giving rise to these great strains by levers. A skilful carpenter never employs many straps, considering them as auxiliaries foreign to his art, and subject to imperfections in workmanship which he cannot discern or amend. We must refer the reader to Nicholson's *Carpenter and Joiner's Assistant* for a more particular account of the various forms of stirrups, screwed rods, and other iron work for carrying tie-beams, &c.

As for those that are necessary for the turning joints of great engines constructed of timber, they make no part of the art of carpentry. (See Note II.)

Examples of different pieces of carpentry.

After having attempted to give a systematic view of the principles of framing carpentry, we shall conclude by giving some examples which will illustrate and confirm the foregoing principles.

Carpentry.

Roof of Greenwich chapel.

Fig. 38, Plate CLXIII. is the roof of the chapel of the Royal Hospital at Greenwich, constructed by Mr S. Wyatt.

	Inches Scantling.
AA is the tie-beam, 57 feet long, spanning 51 feet clear	14 by 12
CC, queen-posts	9 × 12
D, braces	9 × 7
E, straining beam	10 × 7
F, straining piece	6 × 7
G, principal rafters	10 × 7
H, a cambered beam for the platform	9 × 7
B, an iron string, supporting the tie-beam	2 × 2

The trusses are seven feet apart, and the whole is covered with lead, the boarding being supported by horizontal ledgers *h*, *h*, of six by four inches.

This is a beautiful roof, and contains less timber than most of its dimensions. The parts are all disposed with great judgment. Perhaps the iron rod is unnecessary, but it adds great stiffness to the whole.

The iron straps at the rafter feet would have had more effect if not so oblique. Those at the head of the post are very effective.

We may observe, however, that the joints between the straining beam and its braces are not of the best kind, and tend to bruise both the straining beam and the truss beam above it.

St Paul's, Covent Garden.

Fig. 39, the roof of St Paul's, Covent Garden, designed by Mr Hardwick, and constructed by Mr Wapshot in 1796.

AA, tie-beam spanning fifty feet two inches	16 × 12
BB, queen-posts	9 × 8
C, straining beam	10 × 8
D, king-post (fourteen at the joggle)	9 × 8
EE, struts	8 × 7½
FF, auxiliary rafters (at bottom)	10 × 8½
HH, principal rafter (at bottom)	10 × 8½
gg, studs supporting the rafter	8 × 8

The trusses are about ten feet six inches apart, and the dotted lines in the middle compartment show the manner in which the roof is framed under the cupola.

This roof far excels the original one put up by Inigo Jones. One of its trusses contains 198 feet of timber. One of the old roof had 273, but had many inactive timbers, and others ill disposed. The internal truss FCF is admirably contrived for supporting the exterior rafters, without any pressure on the far projecting ends of the tie-beam. The former roof had bent them greatly, so as to appear ungraceful. (See Note KK.)

We think that the camber (six inches) of the tie-beam is rather hurtful, because, by settling, the beam lengthens; and this must be accompanied by a *considerable* sinking of the roof. This will appear by calculation. (See Note LL.)

Birmingham theatre.

Fig. 43, Plate CLXIV., the roof of Birmingham theatre, constructed by Mr George Saunders. The span is eighty feet clear, and the trusses are ten feet apart.

A is an oak corbel	9 × 5
B, inner plate	9 × 9
C, wall-plate	8 × 5½
D, pole-plate	7 × 5
E, tie-beam	15 × 15
F, straining beam	12 × 9
G, oak king-post (in the shaft)	9 × 9
H, oak queen-post (in the shaft)	7 × 9
I, principal rafters	9 × 9
K, common ditto	4 × 2½
L, principal braces	9 and 6 × 9
M, common ditto	6 × 9
N, purlins	7 × 5
Q, straining sill	5½ × 9
S, ridge piece	

This roof is a fine specimen of British carpentry, and is one of the boldest and lightest roofs in Europe. The straining sill, Q, gives a firm abutment to the principal braces, and the space between the posts is 19½ feet wide, affording roomy workshops for the carpenters and other workmen connected with a theatre. The contrivance for taking double hold of the wall, which is very thin, is excellent. There is also added a beam (marked R), bolted down to the tie-beams. The intention of this was to prevent the total failure of so bold a trussing, if any of the tie-beams should fail at the end by rot.

Drury-Lane theatre.

Akin to this roof is fig. 44, Plate CLXIV., the roof of Drury Lane theatre, eighty feet three inches in the clear, and the trusses fifteen feet apart, constructed by Edward Grey Saunders.

A, beams	10 by 7
B, rafters	7 × 7
C, king-posts	12 × 7
D, struts	5 × 7
E, purlins	9 × 5
G, pole-plates	5 × 5
H, gutter plates framed into the beams	12 × 6
I, common rafters	5 × 4
K, tie-beam to the main truss	15 × 12
L, posts to ditto	15 × 12
M, principal braces to ditto	14 and 12 × 12
N, struts	8 × 12
P, straining beams	12 × 12

The main beams are trussed in the middle space with oak trusses five inches square. This was necessary for its width of thirty-two feet, occupied by the carpenters, painters, &c. The great space between the trusses afford good store-rooms, dressing-rooms, &c.

It is probable that this roof has not its equal in the world for lightness, stiffness, and strength. The main truss is so judiciously framed, that each of them will safely bear a load of three hundred tons; so it is not likely that they will ever be quarter loaded. The division of the whole into three parts makes the exterior roofings very light. The strains are admirably kept from the walls, and the walls are even firmly bound together by the roof. They also take off the dead weight from the main truss one third.

Remarks.

The intelligent reader will perceive that all these roofs are on one principle, depending on a truss of three pieces and a straight tie-beam. This is indeed the great principle of a truss, and is a step beyond the roof with two rafters and a king-post. It admits of much greater variety of forms, and of greater extent. We may see that even the middle part may be carried to any space, and yet be flat at top; for the truss-beam may be supported in the middle by an inverted king-post (of timber, not iron), carried by iron or wooden ties from its extremities; and the same ties may carry the horizontal tie-beam K; for till K be torn asunder, or M, M, and P be crippled, nothing can fail.

The roof of St Martin's church in the Fields is constructed on good principles, and every piece properly disposed. But although its span does not exceed forty feet from column to column, it contains more timber in a truss than there is in one of Drury-Lane theatre. The roof of the chapel at Greenwich, that of St Paul's, Covent-Garden, those of Birmingham and Drury-Lane theatres, form a series gradually more perfect. Such specimens afford excellent lessons to the artist. We therefore account them a useful present to the public.

Project by Mr Nicholson.

There is a very ingenious project offered to the public by Mr P. Nicholson. (*Carpenter's Assistant*, p. 68.) He proposes iron rods for king-posts, queen-posts, and all

Carpentry. other situations where beams perform the office of ties. He receives the feet of the braces and struts in a socket very well connected with the foot of his iron king-post; and he secures the feet of his queen-posts from being pushed inwards, by interposing a straining sill. He does not even mortise the foot of his principal rafter into the end of the tie-beam, but sets it in a socket like a shoe, at the end of an iron bar, which is bolted into the tie-beam a good way back.[1] All the parts are formed and disposed with the precision of a person thoroughly acquainted with the subject; and we have not the smallest doubt of the success of the project, and the complete security and durability of his roofs. We abound in iron; but we must send abroad for building timber. This is therefore a valuable project; at the same time, however, let us not overrate its value. Iron is about twelve times stronger than red fir, and is more than twelve times heavier; nor is it cheaper, weight for weight, or strength for strength.

Our illustrations and examples have been chiefly taken from roofs, because they are the most familiar instances of the difficult problems of the art. We could have wished for more room even on this subject. The construction of dome roofs has been, we think, mistaken, and the difficulty is much less than is imagined; we mean in respect of strength; for we grant that the obliquity of the joints, and a general intricacy, increases the trouble of workmanship exceedingly. Wooden bridges form another class equally difficult and important; but our limits are already overpassed, and will not admit them. The principle on which they should all be constructed, without exception, is that of a truss, avoiding all lateral bearings on any of the timbers. In the application of this principle we must further remark, that the angles of our truss should be as acute as possible; therefore we should make it of as few and of as long pieces as we can, taking care to prevent the bending of the truss beams by bridles, which embrace them, but without pressing them to either side. When the truss consists of many pieces, the angles are very obtuse, and the thrusts increase nearly in the duplicate proportion of the number of angles.

Wooden bridges.

Framing of great levers.

With respect to the frames of carpentry which occur in engines and great machines, the varieties are such that it would require a volume to treat of them properly. The principles are already laid down; and if the reader be really interested in the study, he will engage in it with seriousness, and cannot fail of being instructed. We recommend to his consideration, as a specimen of what may be done in this way, the working beam of Hornblower's steam-engine. (See STEAM-ENGINE.) When the beam must act by chains hung from the upper end of arch-heads, the framing there given seems very scientifically constructed; at the same time we think that a strap of wrought iron reaching the whole length of the upper bar (see the figure) would be vastly preferable to those partial plates which the engineer has put there, for the bolts will soon work loose.

But when arches are not necessary, the form employed by Mr Watt is vastly preferable, both for simplicity and for strength. It consists of a simple beam, AB (fig. 45, Plate CLXIV.), having the gudgeon C, on the upper side. The two piston rods are attached to wrought-iron joints, A and B. Two strong struts, DC, EC, rest on the upper side of the gudgeon, and carry an iron string, ADEB, consisting of three pieces, connected with the struts by proper joints of wrought iron. A more minute description is not needed for a clear conception of the principle. No part of this is exposed to a cross strain; even the beam AB might be sawed through at the middle. The iron string is the only part which is stretched; for AC, DC, EC, BC, are all in a state of compression. We have made the angles equal, that all may be as great as possible, and the pressure on the struts and strings a minimum. Mr Watt makes them much lower, as *AdeB*, or *AδεB*. But this is for economy, because the strength is almost insuperable. It might be made with wooden strings; but the workmanship of the joints would more than compensate the cheapness of the materials.

We offer this article to the public with deference, and we hope for an indulgent reception of our essay on a subject which is in a manner new, and would require much study. We have bestowed our chief attention on the strength of the construction, because it is here that persons of the profession have the most scanty information. We beg them not to consider our observations as too refined, and that they will study them with care. One principle runs through the whole; and when that is clearly conceived and familiar to the mind, we venture to say that the practitioner will find it of easy application, and that he will improve every performance by a continual reference to it.

IV.—NOTES.

AA, p. 255. This rule may be somewhat more accurately expressed in these words: From the point at which any three forces meet and balance each other, draw a line in the actual direction of any one of them, and from the extremity of this line draw two others, parallel to the directions of the other two forces respectively; then supposing the pieces affording these two forces to be produced indefinitely at their remoter ends, either of them which is cut by one of the two lines will be compressed, and act as a brace, and either of them which is not cut will be stretched, and act as a tie.

BB, p. 256. It is, however, difficult to imagine how the beam DA can furnish a force iA, to prevent the force Af from carrying the beam BA towards H, when DA only affords a repulsive abutment. The true resolution of the force AE is found by considering the intersection of GE with Ae, which are the directions of the separate forces composing it: these lines meeting in a point a little above r, we may call their intersection r^*: then in the triangle AEr^*, the side Ar^* will represent the pressure on the mitred joint, and r^*E the pressure on the beam HD; and the former being again resolved into AG and Gr^*, we have ultimately AG and $Gr^* + r^*E = GE = AF$, for the horizontal and vertical forces, however they may be modified by intermediate combinations.

CC, p. 257. The reasoning contained in this and some of the subsequent articles may serve as an approximation to the truth in many cases of common occurrence; but the supposition on which it is founded is by no means generally admissible as affording a result mathematically accurate; for, in reality, the distribution of the weight of a roof over the whole extent of the rafters, or the concentration of the whole weight in the point where they meet, is far from being an indifferent alternative, either with respect to the magnitude of the thrusts, or to the proper directions of the abutments or joints. In the case here discussed, where there is no king-post, it is clear that the centre of gravity of the whole roof must be much nearer to the middle of the figure than the angular point, and that consequently the weights supported by the two walls will be very different from those which would be support-

[1] See figures 40, 41, 42, Plate CLXIII., and Mr Nicholson's work, p. 68, where these figures are particularly described.

ed if the whole load were placed at the summit; although, where there is a heavy king-post, supporting also, as it ought to do, about half the weight of the tie-beam, with its floors or ceiling, the case will approach much nearer to the supposition here assumed.

For a common light roof, without a king-post, the calculation or construction is very simple. When two rafters only meet at the summit, they must support each other by a horizontal thrust (see Art. BRIDGE, Prop. Y); and this thrust, acting on each rafter as a lever, of which the lower end is the fulcrum, must be equivalent to the weight, acting at the horizontal distance of the centre of gravity from the fulcrum, which is a quarter of the whole span; consequently the thrust must be to the weight as a quarter of the span to the height, and the compound oblique thrust on the abutment will be represented by the hypotenuse of the triangle of which those lines are the sides; so that if we had a roof of the same height, and of half the breadth, the direction of its rafters would exactly represent the actual direction of the compound thrust on the end of the tie-beam, and would consequently indicate the proper form for the abutment of the given structure.

But in the case of the unequal rafters represented in the figure, the determination becomes more complicated, and we must first find the direction of the mutual thrust of the rafters, which must evidently be such, that the perpendiculars falling on it from each end of the tie-beam may be in the inverse proportion of the motive powers of the weights of the rafters, that is, of the products of those weights into the horizontal distances of the centres of gravity from the respective fulcrums, or into the segments of the tie-beam made by a vertical line passing through the summit, which are proportional to these distances; and if we produce the base of the triangle, and find in it a point, of which the distance is to the length of the tie-beam as the smaller product to the difference of the products, a line drawn from the summit to this point will show the true direction of the thrust; and its magnitude may then be readily determined by dividing either of the products by the respective perpendicular falling on this line.

Where, however, there is a king-post supporting a heavy tie-beam, it is necessary to determine the centre of gravity of the half roof, together with this addition; and the distance of the centre of gravity from the middle will then be to the half span, as the weight of one of the rafters with its load is to the weight of the whole roof, including the tie-beam and ceiling; and if we erect a perpendicular passing through the centre of gravity thus found, and equal to the height, the oblique thrust on the abutment will be in the direction of the line joining the upper end of this perpendicular and the end of the tie-beam.

DD, p. 259. In order to obtain a distinct idea of the operation of the forces concerned in this experiment, we must have recourse to proposition C of this article, and substitute in the formula for the deflection

$$d = a\,t\sqrt{\frac{M}{16f}}\ \text{TANG.}\left(\sqrt{\frac{16f}{M}}\cdot\frac{e}{a}\right),$$

$a = 1$, $t = \frac{8}{6720} = \frac{1}{840}$, $M = 1{,}900{,}000$ pounds, the specific gravity of fir being ·56, $f = 6720$, and $e = 6$, the middle of the pillar being considered as the fixed point: we then find $\sqrt{\frac{16f}{M}}\cdot\frac{e}{a} = 1{\cdot}427$, which is the length of an arc of 81° 45′, and the tangent becomes 6·9, whence we have $d = \frac{1}{840} \times 4{\cdot}2 \times 6{\cdot}9 = {\cdot}0345$, or somewhat more than the thirtieth of an inch; consequently the strength must have been reduced in the proportion of 1·207 to 1. (Art. BRIDGE, Prop. E.) But considering how near the arc thus determined approaches to a quadrant, it is obvious that any slight variations of the quantities concerned in the calculation must have greatly affected the magnitude of the tangent; so that the loss of strength may easily have been considerably greater than this, as it appears to have been found in the experiment. It would, however, scarcely have been expected that such a pillar, however supported, could withstand the pressure of ninety hundredweight, since Emerson informs us that the cohesive strength of a pillar of fir an inch in diameter is only about thirty-five: but supposing the facts correct, the coincidence tends to show the near approach to equality of the forces of cohesion and lateral adhesion, as explained in the introduction to this article.

EE, p. 260. A similar remark of the author has already been noticed in the article BRIDGE, at the end of the fifth section. In the form in which it is here expressed, it becomes still more objectionable; for with whatever part of a circular abutment a rafter equal to the radius may be brought into contact, it is very plain that its opposite end can never be either higher or lower than the original centre of curvature: and even if the curvature were made twice as great, so that the rafter might be equal to the diameter of the circle, it would be necessary that the lower end should slide upwards on the abutment as much as the upper end fell, in order to preserve the contact; and there would obviously be no force in the structure capable of producing such a change as this. Any general curvature of the joint must therefore be totally useless; but a judicious workman will make it somewhat looser below than above, when there is any probability that the rafters will sink, taking care, however, to avoid all bearing too near the surface, lest it should splinter, and, for these reasons combined, making the end a little prominent somewhat above the middle of the surface which rests on the abutment.

With this precaution, the direction of the joint between a rafter and a tie-beam ought to be made precisely perpendicular to the true thrust of the rafter, determined as already explained (Note CC); for, in the first place, unless we trust either to the friction, or to straps, the bearing cannot be more nearly horizontal than this, without danger of the rafters sliding outwards; and, in the second place, if we made it more nearly vertical, we should lessen the vertical pressure on the end of the tie-beam, immediately beyond the joint; a pressure which gives firmness to the wood, by pressing its fibres more closely together, and increasing their lateral adhesion, or rather internal friction. If, however, the tie-beam were not deep enough to receive the whole of the rafter so terminated, without too great a reduction of its depth, it would be proper to make the joint a little flatter, or more horizontal, and to restrain the end from sliding upwards by an iron strap fixed in a proper direction. We should preserve the end of the rafter as little diminished in breadth as possible, when the tie-beam is wide enough to receive it; a moderate thickness, left on each side of the mortise in the tie-beam, being sufficient to assist in securing the connection of the ends of the beam with the intermediate parts.

FF, p. 260. The doctrine of the initial equality of the resistances to compression and extension, as stated in the article BRIDGE, enables us to demonstrate that the transverse strength can never exceed one sixth of that which would be derived from the resistance of all the fibres, co-operating at the distance of the whole depth from a fixed fulcrum, and acting with the weaker of the two powers appropriate to the body. It is true that the results of some direct experiments seem to favour the opinion that

the cohesive power is the weaker; but where the flexure is already considerable, it is probable that this circumstance materially diminishes the primitive power of resisting compression, so that the principles on which the calculation proceeds are by no means strictly applicable to the case of a bar so broken.

GG, p. 261. There seems to be a little confusion in the idea of the possibility of altering the nature of the action of the fibres of a beam by altering the place of the gudgeon in this manner; but the author has very properly abstained from making any practical application of the supposed modification thus introduced. With respect to the strength required for scarfing or joggling, it may be observed, that the whole of the compressed fibres of the concave side may be considered as abutting against the whole of the extended fibres on the convex side; and this abutment is equally divided throughout the length of the beam; so that if the scarfings or joggles in the whole length of the arm of a lever, taken together, are as strong as one half of the depth of the lever, exerting half its powers, from the inequality of tension, there will be no danger of the failing of these joints; and from this principle it will be easy to determine the depth to which the joints ought to extend in any particular case. Hence also we may understand how a beam may become so short as to be incapable of transverse fracture in its whole extent; for the lateral adhesion between the different fibres of wood is generally far inferior to the longitudinal strength of the fibres: and if, for example, it were only one fourth as great, a beam less than twice as long as it is deep would separate, if urged in the middle by a transverse force, into two strata, from its incapacity of affording sufficient abutment, before its longitudinal fibres would give way.

HH, p. 263. If the bolts were sufficiently numerous and sufficiently firm, so as to produce a great degree of adhesion or of friction between the parts, this joint might be made almost as strong as the entire beam, since there is nothing to prevent the co-operation of each side with the other throughout its extent; but much of the strength would be lost if the bolts became loose, even in an inconsiderable degree.

II, p. 265. The author has reasoned upon the direction of straps, as if it were universally necessary to economize their immediate strength only, without regard to the effect produced on the tightness of the joint; but it may happen that the principal purpose of the strap will be answered by its pressing the rafter firmly upon the beam, and this effect may be produced by a certain deviation from the horizontal position, with but little diminution of the strength of the strap; a deviation which has also the advantage of allowing the strap to embrace the whole of the beam, without weakening it by driving a bolt through it. We must not, however, run the risk of crippling the end of the beam, and the straps represented in fig. 38 may be allowed to be somewhat too erect.

KK, p. 266. It does not appear to be desirable that the ends of the rafters should be supported without any pressure on the ends of the beams, since these ends would bear a small weight without any danger of bending, and would thus lessen the pressure on the king-post.

LL, p. 266. The half length being 25 feet, and the camber 6 inches, the excess of the oblique length will be $\sqrt{625 \cdot 25} - 25$, or $\frac{1}{200}$ of a foot, that is, $\frac{1}{16}$ of an inch, which is all that the beam would appear to lengthen in sinking; nor would the settling of the roof be more "considerable" than about a quarter of an inch. But there seems to be no advantage in this deviation of the tie-beam from the rectilinear direction; and the idea, which appears to be entertained by some workmen, that a bent beam partakes of the nature of an arch, is one of the many mischievous fallacies which it is the business of the mathematical theory of carpentry to dispel. (T. Y.)

CARPENTUM, in *Antiquity*, a name common to different kinds of vehicles, including coaches, waggons, and carts. The carriage generally used by the Roman matrons was called carpentum, and usually had two wheels and an arched covering The name is said to be derived by a slight literal conversion from *Carmenta*, the mother of Evander. In the second Punic war, women were prohibited the use of the carpentum by the Oppian law, which, however, was soon afterwards repealed. Carpenta or covered carts were much employed by the Britons, Gauls, and other northern nations, in their military expeditions. These, together with the commoner kind of waggons, were included under the general term *carri* or *carra*, from the Celtic *carr*. (See Cæsar's *Commentaries*).

CARPET. This term is supposed to be derived from Cairo (whence also the French *Cairan*, a Turkey carpet), and from the Latin *tapes*, tapestry, corresponding to the Italian *carpetta*, and the Dutch *karpet*. It is legitimately applied to an article of manufacture used for covering the floors of chambers, or spreading on the ground, although, while it was a novelty in Europe, tables also were covered with it.

Carpets and rugs were manufactured at a very remote period in Egypt, India, and China; but those of Persia and Turkey are the most celebrated. They were originally used for sitting and reclining upon, as may still be observed in Eastern countries, where they constitute the entire furniture of the people. In Egypt they were first applied to religious purposes by the priests of Heliopolis, and were also used to garnish the palaces of the Pharaohs. It was also a custom of antiquity to place them under the couches of guests at banquets. Sardinian carpets are mentioned by Plato the comic poet, as being disposed in this manner—"beneath the ivory feet of purple-cushioned couches." The carpets of the Homeric age were generally white or plain cloths; but they were also sometimes produced with various colours and embroidered designs. At the supper of Iphicrates, purple carpets were spread on the floor; and at the magnificent banquet of Ptolemy Philadelphus (an account of which is given by Callixenus of Rhodes) we learn that underneath 200 golden couches "were strewed purple carpets of the finest wool, with the carpet pattern on both sides; and there were handsomely embroidered rugs, very beautifully elaborated with figures. Besides this," he adds, "thin Persian cloths covered all the centre space where the guests walked, having most accurate representations of animals embroidered on them;" (*Athenæus*, v. 26.) The Babylonians, who were very skilful in weaving cloths of divers colours (Pliny, viii. 48), delineated upon their carpets entire groups of human figures, together with such fabulous animals as the dragon, the sphynx, and the griffin. These were numbered among the luxuries of Heliogabalus. On the tomb of Cyrus was spread a purple Babylonian carpet, and another covered the bed whereon his body was placed (Arrian, vi. 29). These carpets were exported in considerable quantities to Greece and Rome, where they were highly esteemed. Carthage was also noted by Hermippus, Antiphanes, and others, for its magnificent carpets.

Sir J. Gardiner Wilkinson gives us an account of an ancient carpet-rug of Egyptian manufacture. "This rug," he tells us, "is made like many cloths of the present day,

with woollen threads, on linen strings. In the centre is the figure of a boy in white, with a goose above, the hieroglyphic of a 'child,' upon a green ground, around which is a border composed of red and blue lines," &c. (*Manners and Customs of the Ancient Egyptians*, vol. iii., pp. 141-2.) He further informs us that there are in the Turin Museum some specimens of worked worsted upon linen, "in which the linen threads of the weft had been picked out, and coloured worsted sewed on the warp." In these two examples we have evidence of the existence, at a very early time, of a system of tapestry-weaving. The ancient carpet manufacture of the Asiatic countries may resolve itself under the appellation of needle-work. Of this, the present process of carpet-weaving in Persia and Turkey, and the tapestry manufacture of France, may be considered as fitting examples. The tapestry, as is well known, consists of woollen or other threads sewed on the strings of the warp, by means of small shuttle-needles. The Persian carpet is formed by knotting into the warp tuft after tuft of woollen yarn, over each row of which a woof shot is passed, the fingers being here employed instead of the shuttle-needles, as the fabric is of a coarser description. In both methods the principle is the same. Both are formed in looms of very simple construction, the warp threads are arranged in parallel order, whether upright or horizontal, and the fabric and pattern are produced by coloured threads, hand-wrought upon the warp. This may be designated the hand-wrought or needle-work method, which only makes one stitch or loop at a time, in contradistinction to the machine-wrought process, the result of mechanical appliances, whereby a thousand stitches are effected at once. Herein lies the essential difference between the ancient and modern, the simple and complex carpet-manufacture.

In Persia there are entire tribes and families whose only occupation is that of carpet-weaving. These dispose of their productions at the bazaars to native merchants, who remove them to Smyrna or Constantinople, where they meet with European purchasers. The trade in real Persian carpets is, however, very limited, owing to their small size. They are seldom larger than hearth-rugs, long and narrow. Very many of them, moreover, are considerably tarnished by exposure in bazaars, if they have not indeed been already used. To render them more saleable they are cleaned. This is done by cropping the surface, which in some cases is shaved quite close to the knot, hence a great proportion of those brought to this country have not their original richness and depth of pile. Felted carpets or *nurmuds* are also made in Persia, but do not constitute an export commodity. Sir Henry Bethune, late Persian ambassador, had in his possession a very singular specimen of this felt carpeting, in which coloured tufts of worsted had been inserted during the process of manufacture, producing a regular pattern when finished.

The greater part of those Turkey carpets imported into England are manufactured at Ushak or Ouchak, in the province of Aïdin, about six days' journey from Smyrna, and rugs principally at Kulah or Koula, an adjacent village. In the provinces of Hoodavendigniar, Adana, and Nish, numerous households are employed in their production, as also in the districts of Bozah, the city of Aleppo, and the villages of Trebizond. Here and there, throughout Caramania, such carpets are also made. The Turcomans of Tripoli, the women of Candia, and the peasantry of Tunis and Algiers, are likewise engaged in their fabrication. In none of these places, however, does any large manufactory exist; the carpets are the work of families and households. These carpets are woven in one piece, and there is this notable peculiarity in their manufacture, that the same pattern is never again exactly reproduced; no two carpets are quite alike. The patterns are very remarkable, and their origin is unknown even to Mussulmans. The Turkey carpet pattern represents inlaid jewelled work, which accords with Eastern tales of jewels and diamonds. If this were rightly understood, it would prevent such speculations as those of Mr Redgrave in his Great Exhibition Report on Design, where he remarks, that "the Turkish carpets are generally designed with a *flat* border of flowers of the natural size, and with a centre of larger forms conventionalized in some cases even to the extent of obscuring the forms—a fault to be avoided." This is doubtless a very ingenious mode of accounting for the curious forms of a Turkey carpet; but these, however fantastic, are never obscured, nor are there any flowers, *flat* or otherwise, in the borders or elsewhere. The great beauty of these carpets lies in the equal balance of colour, of dull neutral shades, somewhat sombre in effect.

Generally throughout British India the carpet manufacture is carried on. At Benares and Moorshedabad are produced velvet carpets with gold embroidery. A very elaborate carpet, sent from Cashmere to the Great Exhibition by Maharajah Goolab Singh, was composed entirely of silk, and excited great admiration. In every square foot of this carpet, we are informed, there were at least 10,000 ties or knots. Silk embroidered hookah carpets are made at Lahore, Mooltan, Khyrpoor, Tanjore, and Bengal; cotton carpets, or *satrunjees*, at Rungpore, Agra, and Sasseram; printed cotton carpets at Ahmedabad; printed floorcloth at Mooltan. Woollen carpets are far more extensively manufactured; some of which come from Ellore, Mirzapore, and Goruckpore, but the principal manufacture is at Masulipatam, 292 miles north from Madras. There the capital and enterprise of this country have lent their aid to the rather tardy movements of the natives, and this article is now in general demand. Of late years linen warp has been introduced instead of cotton, and the fabric is thereby much improved. The designs of the Indian carpets have more regularity than those of Turkey, and the colours are mostly warm negatives, enlivened with brilliant hues interspersed. For the introduction of Masulipatam carpets, as of many others into the trade of this country, we are indebted to the firm of Watson, Bell, & Co., whose Indian connection is our sole means of obtaining these beautiful fabrics.

The total value of Persian, Turkey, and Indian carpets imported into England, may be computed at about L.20,000 per annum.

Oriental carpets were first introduced into Spain by the Moors; and at a later date the Venetians imported them into Italy, and supplied western Europe with this luxurious manufacture. We have frequent mention of them during the middle ages, and their costliness and magnificence are celebrated in the illuminated pages of fabliaux and romances. They were spread in the presence-chambers of royalty, before the high altars of chapels and cathedrals, in the bowers of "ladyes faire," and on the summer grass. Many articles of furniture were also covered with them—beds, couches, tables, and regal faldestols; but here it becomes difficult to distinguish between carpet and tapestry, both being used promiscuously. Tapestry of Baldekine or Baldachine (from Baldak, ancient name of Baghdad), was a carpet inwrought with gold and silver threads. Such were carried on poles, and uplifted as a canopy over the host, and over great personages in procession. The troubadours had carpets of gold embroidery which they laid upon the grass beneath them. Hearth-rugs and throne carpets, gorgeously emblazoned with heraldic centre-pieces, were the handiwork of high-born dames during the romance period. To some of these were attached fringes, but such were more usually composed of the fag-ends of the warp, like those of Persia, India, and Turkey. A black velvet carpet, "fringed with silver and gold, and lined with taffeta," is enumerated in the inventory of Archbishop Parke's household furniture in 1577. Rushes were strewn on the floor of Queen Mary's presence-cham-

Carpet. ber, and that of Elizabeth had the additional covering of a Turkey carpet. Long prior to this, however, Eastern carpets had been introduced. In the reign of Edward VI. we read that before communion-tables were placed—

> " —— —— Carpets full gay,
> That wrought were in the Orient."

Chequered matting appears to have been very generally used about the fifteenth century.[1] In Lydgate's metrical life of St Edmund (MS. Harl. No. 2278), is a representation of the room wherein that saint was born; the floor is covered with chequered matting, and a fringed hearth-rug of Gothic design is before the fireplace. Carpets composed entirely of leather strips interlaced together may be seen in our antiquarian museums. A sample of this description was lately prepared for the inspection of the new houses of parliament, and offered as a covering for their halls and passages, but was rejected.

In the reign of Henry IV. the carpet manufacture appears to have been introduced from Persia into France. Colbert, the minister of Louis XIV., established the manufactory at Beauvais in 1664, which is now in the hands of the French government, and produces very artistic specimens. A variety of these, "in Turkish, Peruvian, and Chinese styles," was exhibited at London in 1851. The national manufactory of Gobelins, which likewise sent its beautiful carpets and tapestry to the Great Exhibition, was established shortly after that of Beauvais. It was purchased in 1677 by Colbert from the Gobelin family, whose progenitors, a century ago (Gilles and Jean Gobelin), brought their art, as was supposed, from Flanders. An attempt was made, in the time of Henry VIII., by William Sheldon, to start this manufacture in England; but under the patronage of James I. it was more successfully established, with the superintendence of Sir Francis Crane, at Mortlake in Surrey, where both carpets and tapestry were produced. Toward this object the sum of L.2676 sterling was contributed by its royal patron, and French weavers were brought over to assist. But it does not appear that anything considerable was effected, until after the revocation of the edict of Nantes, in 1685, when artizans of every trade fled to this country, among whom were tapestry and carpet weavers, who settled in various parts. About the year 1750, Mr Moore was awarded a premium by the Society of Arts for the best imitation Turkey carpets; and Parisot conducted an establishment for their manufacture at Paddington, under the patronage of the Duke of Cumberland. Subsequently, carpets were wrought on the same principle at Axminster, in Devonshire, whence the name; and afterwards at Wilton, where they are still manufactured by Messrs Blackmore. The Board of Trustees for the Encouragement of Arts and Manufactures in Scotland offered prizes for the best Persian and Turkey carpets, which were carried off by Gregory, Thomsons, & Co. of Kilmarnock, and Whytock & Co. of Edinburgh. About ninety years previously they had been made in the vicinity of Holyrood Palace. These expensive and magnificent carpets are now made in many parts of Europe, but more particularly at the Gobelins manufactory, at Aubusson and Fellitin, in the department of Creuse, at the Manufacture Royale de Tapis de Tournai in Belgium, and at Deventer in the Netherlands. They are also made in London and Kidderminster.

Hitherto we have been treating of the simple hand-wrought or needle-work process, which implies great expense and waste of time and labour, and is therefore not calculated to supply a general demand. The machine-wrought fabric now claims our attention; and first in order, the common ingrain, Kidderminster or Scotch carpet, which is made in many parts of Scotland, the north of England, and in the United States of America. This consists of worsted warp traversed by woollen weft, and is woven in pieces about a yard wide. It is composed of two distinct webs interlaced together at one operation, and is therefore a double or two-ply carpet, similar on either side. In this article only two colours can with propriety be introduced, as otherwise it has a striped or mixed appearance. A pure or plain colour can only be obtained where the weft traverses the warp of the same colour. Suppose a crimson figure on a maroon ground; the one web is maroon, the other is crimson, and the pattern is produced by these intersecting and decussating each other at points predetermined; thus what is crimson on one side is maroon on the other, and *vice versa.* One beam contains the warp of both plies, arranged in two tiers, which is passed through the *mails* or metallic eyes of the harness—two threads through each eye—and thence through the reed. The harness draws up certain warp threads, to admit of the passage of the shuttle with the weft, the pattern depending upon such warp threads as are so drawn up. This was formerly effected by means of a revolving barrel, whose surface was studded with pins, which by rotation acted upon the warp threads. These studs being arranged so as to produce one pattern, a separate barrel or a new arrangement of the studs was requisite for every other pattern. But this machine is now superseded by the more efficient Jacquard apparatus, which produces the pattern by means of an endless chain of perforated cards working against parallel rows of needles. This double fabric is also made in France, and sprigs of divers colours inserted. A detailed account of this process, with elaborate diagrams, is given by M. Roland de la Platière, in the *Encyclopédie Méthodique.*

An improvement upon the Kidderminster carpet is the triple or three-ply fabric, the invention of Mr Thomas Morton of Kilmarnock. This is composed of three distinct webs, which, by interchanging their threads, produce the pattern on both sides. A variety of colour is thus obtained, and the texture is of great thickness and durability.

Figured Venetian carpeting is of similar description; here the woof is completely covered by a heavy body of warp. Dutch carpeting is much inferior in quality, and was originally made of cow-hair, but now of the coarsest wool. Neither fabric has great capabilities of design; simple diced patterns are wrought in the Venetian, stripes and chequers in the Dutch.

The Brussels carpet is a very superior texture. It is composed of worsted and linen, and has a rich corded appearance. The figures are raised entirely from the warp, by inserting a series of wires between the linen foundation and the superficial yarn. These wires are afterwards withdrawn, leaving a looped surface. In this manufacture there is a great waste of material, and the colours are usually limited to five. Each colour has its continuous layer of thread, running from end to end of the web, which rises to the surface at intervals indicated by the design, and then sinks into the body of the fabric. Thus there are five layers or covers, only a fifth part of which is visible; and owing to the irregularity of their ascent to the surface, they cannot be placed upon one beam, but each thread is wound on a separate bobbin, with a weight attached to give a proper tension. These bobbins are arranged in five frames jutting out behind the loom—260 bobbins in each frame for the ordinary width. Additional frames are requisite for additional colours introduced; but where more than five are engaged the pattern is rather indistinct. The threads of all the bobbins are then drawn through the harness, heddles, and reed, to unite with the linen yarn in the compound fabric, the Jacquard machine being employed to

[1] The same article is produced in many parts of Asia from the grassy fibres of the ratan. A superior description is now made in this country from cocoa-nut fibre and Manillan flax.

produce the pattern. Brussels carpets were first introduced into Wilton about a century ago, from Tournai in Belgium. Kidderminster is now the chief seat of this manufacture, where upwards of 2000 looms are in operation.

Moquette or Wilton carpets are woven in the same manner, and differ only in this, that the loops are cut open into an elastic velvet pile. To effect this, the wires are not circular as in the Brussels fabric, but flat, and furnished with a groove in the upper edge, wherein the sharp point of a knife is inserted and drawn across the yarn, cutting the pile. These carpets, besides being manufactured in many parts of England and Scotland, are also made in France.

We now proceed to describe a very ingenious improvement in this branch of carpet manufacture—the invention of Mr Richard Whytock of Edinburgh. This is a combination of the arts of printing and weaving, at the same time simplifying both. These arts may be said to be combined when any *woven* fabric is *printed;* but here the process is reversed, the threads being printed before they are in cloth. This, to be sure, is the case when warps are printed and then woven; but the grand novelty of this invention is that the *threads* are printed before even the *warp* is formed. One thread, or two treated as one, in some cases miles in length, are coloured by steps of half an inch, faster than a swift runner would make the distance. When these threads have been all parti-coloured in this manner, they form the elements, as it were, of the intended design or fabric. Singly, they exhibit no regular figure or pattern; but when arranged in their proper order, ready for the weaver's beam, the figure comes into view, much elongated of course, inasmuch as 18 feet of the warp will sometimes be gathered into 4 feet of cloth, in order to secure the due proportions of the intended object. It has been said that the two combined arts of printing and weaving are simplified by this contrivance. With regard to the weaving: *First,* The loom occupies only one-third of the space in length that the Brussels loom requires. *Second,* The latter must have 1300 little beams or bobbins, from which the worsted pile has to be gathered; whereas this loom requires only one beam for the whole of the worsted threads. *Third,* While the Brussels or Wilton, on a web of 27 inches, requires for the best fabric 2860 threads, only 780 are here requisite—one layer instead of five—to produce as good or a better surface. *Lastly,* While the number of colours in succession lengthwise, on the old principle, must not exceed six or seven, upwards of twenty or thirty can be introduced by the new method. Then, again, as a simplification of the printing process: whereas formerly a change of blocks was required for every change of pattern, in this new process the same blocks serve for all patterns—as the pen serves for every form of type. Many of those manufacturers who are now availing themselves of this invention do not see wherein its true economy consists. If an object, say a rosebud, recurs a thousand times in the length of a web, at intervals of 4 feet, the block printer must apply his block a thousand times to point the opening bud; but here the buds are congregated, so that one stroke may dye them all. If it be desired to have a thousand buds in the length of the web, let a thread be wound round a hollow cylinder a thousand times, and a traversing wheel charged with colour be passed across the coil. The thread when uncoiled will be found to be marked in a thousand places, exactly where it is wanted to tip the opening bud with red from end to end of the web. Design-paper, whereon the pattern is indicated in small squares, serves as a guide to the printer; each square being one stroke of the colour-pulley. After the threads are thus streaked across with colour, they are removed from the cylinder or drum, and the dyes are fixed by the action of steam. The threads are then arranged in setting frames, according to the squares of the design-paper, to constitute the warp of the projected web. The Jacquard is now so far at a discount, and the loom restored to nearly the same simplicity as of old, when

"Between two trees the web was hung."

The principle here referred to is only in its infancy. The works of the first masters may yet be multiplied by this process, if they will condescend to furnish the cartoons. Already flowers are produced which the botanist can classify without mistake.

Like every other improvement, this invention met with considerable opposition, particularly on the part of manufacturers and dealers. During the first fourteen years, the number of looms employed gradually increased from one to fifty-six, the greatest number in operation at Lasswade in 1847. Now, so extensive is the manufacture in England, that one house produces to the extent of half a million sterling per annum, having upwards of 300 looms at work by steam-power. It is gratifying to learn that these power-looms, instead of throwing out of employment, engage more operatives with better wages and easier work.[1] Messrs Henderson and Widnell of Lasswade, John Crossley and Sons of Halifax, Pardoe, Hoomans, and Pardoe of Kidderminster, and Sutherland and Tod of Lanark, are the principal manufacturers engaged upon this patent. An extraordinary consequence upon the introduction of this article is that it has not interfered with other branches of the carpet manufacture, not one of which appears to have been diminished. There is, therefore, an addition to the trade of the country, to the whole amount of its produce, itself no mean result; the whole trade being at least doubled, as far as fine carpets are concerned. Whytock's carpets are known under the designation of Patent Tapestry and Velvet Pile Carpets. Rugs, table-covers, fine velvets, and tapestry hangings, are wrought on the same principle.

Another great improvement in carpet-making, which originated also in Scotland, was patented by Mr James Templeton of Glasgow. It is on the chenille principle, and consists of a process of double weaving. First a thin striped fabric is made; and this, when cut up, is again woven into a denser fabric for carpets, rugs, and table-covers. The chenille stripes, like the parti-coloured threads in Whytock's invention, form the elements of the second fabric, only those elements go to compose the woof instead of the warp, as in the former case. Extremely beautiful carpets have been made on this principle, and these being woven in large squares, have interfered much with the Tournai or Axminster carpets, having the same depth of pile, without being so expensive. Hitherto, however, the manufacture has been confined to the place where it originated.

Patent wool mosaic is another novelty. This manufacture was introduced into England from Germany. It is produced by cementing with caoutchouc a close velvet pile on a plain cloth. Messrs John Crossley and Sons of Halifax have brought out some admirable specimens of this mosaic-work, in carpets, rugs, and hangings for walls; but as yet this method has been more extensively applied to the manufacture of small articles.

A very cheap description of carpet is now made near Manchester. It is first woven in plain colours by steam-power, under Seivier's patent, by Bright & Co. It is then printed with coloured blocks by machinery patented by Burch & Co. This article has a large export sale.

The carpet manufacture is rapidly increasing in Great Britain. Upwards of 5000 looms, it is computed, are now in operation, upon every description. The wages of the operatives may average from 15s. to 30s. per week.

It remains to speak of carpet design. This matter is regulated by prevailing fashion and caprice, under the ever-varying semblance of good taste. There are revolutions in decorative art, as in all things else, and in these carpet design is involved. An acute observer can discover here symptomatic indications of national or individual character. The supremacy of Gothic architecture, in our day, implies the revival of mediæval art. Simple ornamental designs, in quiet and subdued colouring, are now about to take the place of their more brilliant predecessors. Many colours will only be tolerated in Moorish and Arabesque ornament, or in the *bizarre* Turkey carpet. But this reformation is not yet general. (A. W—K.)

CARPET-*Knights,* a denomination sometimes given to gown-men and others of peaceable professions, who, when they receive the honour of knighthood, usually kneel on a carpet; and thus are distinguished from knights created in the camp, or on the field of battle.

CARPI, a town of Italy, in the duchy of Modena, 10 miles from the city of that name. Its public buildings worthy of note are the citadel and the cathedral. Pop. 5300.

CARPI, *Girolamo da,* a historical and portrait painter, was born at Ferrara in 1501, and was one of the most promising pupils in the school of Benvenuto Garofalo. On leav-

[1] In the United States there were fifty of Mr Bigelow's power-looms at work upon tapestry carpeting in 1851. An inconsistent prejudice, however, exists there against indigenous produce, and if an article does not come from "Europe" it is in many cases a sufficient cause of condemnation. A similar prejudice prevails here in favour of foreign manufacture.

ing Ferrara he spent several years at Parma and Modena, carefully copying the works of Correggio and Parmigiano; and on his return he executed some original paintings for the churches of Bologna and Ferrara, which so closely resembled the works of Correggio as to have been attributed to that artist. His finest paintings are, *The descent of the Holy Spirit*, in the church of St Francis at Rovigi; a *Madonna, St Giorgio, St Maurelio*, and *St Girolamo*, at Ferrara; the *Adoration of the Magi*, the *Madonna*, and *St Catherine*, at Bologna. He died in 1556.

Carpi, *Ugo da*, an Italian painter who flourished about the year 1500. He is chiefly remarkable as having been supposed the inventor of that species of engraving on wood distinguished by the name of chiaroscuro, in imitation of drawing. Huber, Heinecken, and Breitkopf, however, have distinctly proved that the art of printing in chiaroscuro was known long before in Germany; and have produced existing works of Jan Ulric Pilguin and of Mair, who flourished before the time of Ugo. One of Mair's prints of this sort is dated 1499; the earliest of Da Carpi's is 1518. Printing in chiaroscuro is performed by using several blocks. Ugo da Carpi usually had three; the first for the outline and dark shadows, the second for the lighter shadows, and the third for the half tint. In this manner he struck off prints after several designs, and the cartoons of Raphael, particularly one of the Sibyl, a Descent from the Cross, and the History of Simon the Sorcerer. Carpi died about 1530. The art was brought to a high degree of perfection by Baldassare Peruzzi of Siena, and Parmigiano.

CARPINI, Giovanni di Plano, a Franciscan monk, who about 1246 was sent by pope Innocent IV. to the Great Khan of Tartary, to convert him to Christianity. The mission reached the Mongolian monarch somewhere to the north of the great desert east of the Caspian; where they were long detained, but at last dismissed. Carpini wrote an account of his travels in Latin, an abstract of which, with an Italian translation, appeared in the *Raccolta* of Ramusio, and has been transcribed into the *Navigations and Discoveries* of our own Hakluyt. After his return from his perilous eastern journey, Carpini devoted his life to preaching the gospel in Bohemia, Hungary, Denmark, and Norway. He was born about 1210, and reached extreme old age. For an account of his eastern travels, see Geography.

CARPINO, a city of Italy, in the Neapolitan province Capitanata. It is situated on Mount Gargano. Pop. 5500.

CARPOCRATIANS, a branch of the ancient Gnostics, so called from *Carpocrates*, who in the second century revived the errors of Simon Magus, Menander, Saturinus, and other Gnostics. He owned with them one sole principle and author of all things, whose name as well as nature was unknown. He maintained that the world was created by angels; and he opposed the divinity of Christ—representing him as a mere man, born of Joseph and Mary in the ordinary course of nature, though possessed of uncommon gifts, which set him above other creatures. He inculcated a community of women; and not only gave his disciples license to sin, but imposed on them the necessity of sinning; for he taught that the soul could not be saved till it had committed all kinds of abominations.

CARPOLOGY, that part of botany which treats of the structure of seed-vessels and seeds.

CARRAC or Carraca, the name given by the Portuguese to the vessels which they formerly sent to Brazil and the East Indies. They were of great size and extraordinary depth, and fitted for war as well as burden.

CARRARA, a town of Italy, in the province of Massa-Carrara, about 60 miles S.W. of Modena. N. Lat. 44. 4., E. Long. 10. 7. It stands on a rising ground near the river Avenza, and at a short distance from the Mediterranean. The principal buildings are the collegiate church, the church of La Madonna delle Grazie, and the ducal palace. In the principal square is a colossal statue of one of the duchesses of Modena. The cheapness and excellence of the marble attracts a number of artists to Carrara, where they are formed into an academy. The quarries (from which it derives its name) give employment to the most of the inhabitants. The town is nearly on the site of the ancient Etrurian Luna. Pop. about 6200.

Carrara *Marble*, a species of white marble, which was called *marmor lunense*, and *ligustrium*, by the ancients. It is distinguished from the Parian by the fineness of its grain and superior hardness.

CARRENNO DE MIRANDA, Don Juan, an eminent Spanish painter (1614–1681), studied under Pedro de las Cuevas and Bartolomé Roman. He was appointed painter to the court by Philip IV., and as a colourist is ranked by the Spaniards with Titian and Vandyk. His most celebrated paintings are, a *Magdalen in the Desert*, at Madrid; a *Holy Family*, at Toledo; and a *Baptism of our Saviour*, at Alcala de Henares.

CARRIAGE, a vehicle for the conveyance of persons, goods, merchandise, &c., from place to place. For the construction and mechanical principles of wheel-carriages, see Mechanics.

CARRICK, one of the three districts into which the county of Ayrshire, in Scotland, is divided—Kyle and Cunningham being the other two. The eldest son of the reigning sovereign, as prince of Scotland, enjoys the title of Earl of Carrick.

Carrick-on-Shannon, a market and post-town in the county of Leitrim, Ireland, about 98 miles N.W. from Dublin. N. Lat. 53. 57., W. Long. 8. 5. It stands on the left bank of the Shannon, and contains an Established church, Roman Catholic chapel, county jail, court-house, infirmary, &c. Before the Union it returned two members to the Irish parliament. Its trade and industry are purely local. Pop. 1796.

Carrick-on-Suir, a town of Ireland, county of Tipperary, province of Munster, situated on the Suir, 12 miles south of Clonmel. It was formerly a walled town, and contains some very ancient buildings, such as the bridge, the castle, and the parish church. The other public edifices of importance are the Catholic chapel, the prison, the workhouse of the Union, and the barracks. The town exports a little grain, and has some unimportant cotton manufactures. Pop. (1851) 8202.

CARRICKFERGUS, a maritime county of a town, including the parliamentary borough of the same name, in the province of Ulster, in Ireland. It is surrounded by the county of Antrim on all sides, except the south, which is skirted by the Bay of Carrickfergus (Belfast Lough). It comprises an area of 26 square miles, or 16,700 acres. The surface is in general hilly. Lough Morne, a lake of about 90 acres in extent, is 556 feet above the level of the sea, and the highest mountain, Slieve True, which commands a magnificent prospect, attains an elevation of 1100 feet; but the land near the sea-shore is an alluvial plain. The farms are small, except in the hilly district, where grazing is carried on. The chief crops are oats and potatoes, for which sea-weed, with lime and vegetable matter, forms the manure; and the district has long been famous for the manufacture of cheese. The fisheries are valuable and extensive, and the oysters taken off this coast are highly prized for their size and flavour. About a mile and a-half from the town, on the property of the Marquis of Downshire, rock-salt of remarkable purity and great thickness has recently been discovered, but all searches after coal in this district have proved abortive. The amount of property valued under 6th and 7th Will. IV., c. 84 (Griffith's valuation), is L.13,521.

According to ecclesiastical arrangement, this county forms a single rectory in the diocese of Connor. The population in 1834 numbered 8860 persons, of whom 1387 were of the Established Church; 6499 were Presbyterians and other

Carrickfergus.

Protestant Dissenters, and 974 were Roman Catholics. The entire population of the county and town in 1851 was 8520.

The town of Carrickfergus, from which the county and adjoining bay take their name, is the only place of importance in the district. The town stretches along the shore of Belfast Lough about one mile in length, and consists of the old or walled town in the centre, the Irish quarter on the west, and the Scotch quarter on the east; the latter being chiefly inhabited by fishermen, descendants from a colony driven by religious persecution from Galloway and Argyllshire about the year 1665. The town is irregularly built, and deficient in neatness. The principal building is the old castle, standing on the projecting rock from which the town derives a portion of its name, formerly a place of much strength, and still maintained as an arsenal, and mounted with heavy guns. The ancient donjon or keep, 90 feet in height, is still in good preservation.

The parish church, an antiquated cruciform structure, was originally a chapel or oratory dependant on a Franciscan monastery in another part of the town. The entrance to a subterranean passage between the two establishments is still visible under the communion-table of the church.

The gaol, built on the site of the above-mentioned monastery, was formerly the county of Antrim prison. The court-house, which adjoins the gaol, is a neat building of modern erection, and when Carrickfergus was the county town of Antrim (which it ceased to be in 1850), the assizes were held here. The other public buildings in the town are, the market-place, the Roman Catholic chapel, and meeting-houses for different sects of Protestant Dissenters.

The town has some little trade and manufacture, and vessels of 100 tons burthen can now discharge at the landing pier; but the superior advantages of the neighbouring town of Belfast hinder the extension of the maritime trade of Carrickfergus, which is confined to the import of coal and the export of cattle and grain.

In the reign of Queen Elizabeth the town obtained a charter confirming and extending its former privileges. The corporation was regulated, and the mayor received the jurisdiction of high admiral of the adjoining seas. This charter was confirmed by James I., who added the additional privilege of sending two burgesses to the Irish parliament. The corporation, styled "the mayor, sheriffs, burgesses, and commonalty of the town of Carrickfergus," were superseded, under the provisions of the Municipal Reform act, by a board of municipal commissioners, in whom the corporate property is vested. Originally the corporation property comprised all the land within the county of the town, but by degrees it was wasted down to its present value of about L.330 per annum.

In 1182, John De Courcy, to whom Henry II. had granted all the parts of Ulster he could obtain possession of by the sword, fixed a colony in this district. De Courcy built the castle which afterwards came into possession of the De Lacy family, who, being ejected, invited Edward Bruce to besiege it. After a desperate resistance the garrison surrendered. In 1386, the town was burned by the Scots; and in 1400 destroyed by the combined Scots and Irish. Subsequently, it suffered much by famine and the occasional assaults of the neighbouring Irish chieftains, whose favour the townsmen were at length necessitated to secure by the payment of an annual tribute.

In the reign of Charles I., many Scotch Covenanters settled in this neighbourhood to avoid the persecution directed against them. In the civil wars, in 1641, &c., Carrickfergus was one of the chief places of refuge for the Protestants of the county of Antrim; and on July 10, 1642, the first presbytery held in Ireland met here. In that year the garrison was commanded by General Munroe, who having afterwards relinquished the cause of the English parliament, was, in 1648, surprised and taken prisoner by Sir Robert Adair, who had been sent for the purpose with a troop of horse from Lisburn by General Monk. The town was taken possession of for the English parliament. Carrickfergus was held by the partisans of James II., but surrendered in 1689 to the forces under King William's general Schomberg; and in 1690 was visited by King William, who landed here on his expedition to Ireland.

Carrickmacross ‖ Carrier.

In the beginning of the year 1760 it was unexpectedly surprised by a French squadron under Commodore Thourot, who landed with about 1000 men, and, after holding the place for a few days, evacuated it on the approach of the English troops. The French squadron was attacked two days afterwards near the Isle of Man, by the Æolus, Pallas, and Brilliant frigates, under the command of Captain Elliott, and Commodore Thourot was killed in the action. In the year 1778 the town was alarmed by the sudden appearance of the celebrated Paul Jones in his ship the Ranger; but he left without molesting the town, having, however, succeeded in capturing the Drake, a British sloop-of-war.

The population of the town of Carrickfergus in 1851 was 3543, being 342 less than in 1841. The borough now returns one member to the imperial parliament; the constituency, under 13th and 14th Vict. cap. 69, in 1853, numbered 1195. There is a weekly market on Saturdays, a butter market on Mondays, and a monthly market for the sale of cattle.—(M'Skimin's *History of Carrickfergus;* Thorne's *Irish Almanac for* 1854.) (H. S—R.)

CARRICKMACROSS, a market-town of Ireland, in the county of Monaghan, province of Ulster, 14 miles from Dundalk. The principal public buildings are the parish church and the union workhouse. The ruins of a large castle belonging to the Essex family are to be seen in the neighbourhood. In the town there is a large distillery; and the trade in grain also is considerable. Pop. (1851) 4268, including 1734 in the workhouse.

CARRIER, in its general acceptation, is a person who conveys the goods of another for hire. In its mere colloquial use it was applied to the class of men, now rendered comparatively obsolete by the railway system, who conveyed goods in carts or waggons on the public roads. In jurisprudence, however, the term is collectively applied to all conveyers of property, whether by land or water; and in this sense the late changes and enlargements of the system of transit throughout the world have given additional importance to the subject. The law by which carriers, both by land and sea, are made responsible for the goods intrusted to them, is founded on the prætorian edict of the civil law, to which the ninth title of the fourth book of the Pandects is devoted. The edict itself is contained in these few words, "*Nautæ, Caupones, Stabularii, quod cujusque salvum fore receperint, nisi restituent, in eos judicium dabo.*" The beautiful simplicity of the rule so announced has had a most beneficial influence on the commerce of the world. Throughout the great civilized region, which took its law directly from the Roman fountain, and through the other less civilized countries which followed their commercial code, it laid a foundation for the principle, that the carrier's engagement to the public is a contract of indemnity. It bound him, in the general case, to deliver what he had been intrusted with, or its value; thus sweeping away all secondary questions or discussions as to the conditions of more or less culpability on his part under which loss or damage may have occurred; and it left any limitations on this general responsibility to be separately adjusted by special contract.

The evident utility of the principle caused its adoption in the common law of England, though, without acknowledgment of the source whence it was derived. Lord Mansfield, in Forward *v.* Pittard (1 T. R. 27), thus clearly laid down the principle: "By the custom of the realm—that is, by the common law—a carrier is of the nature of an insurer It is laid down that he is liable for every accident,

Carrier-pigeon.

except by the act of God, or the king's enemies * * * To prevent litigation, collusion, and the necessity of going into circumstances impossible to be unravelled, the law presumes against the carrier, unless it was done by the king's enemies, or by such act as could not happen by the intervention of man; as storms, lightning, or tempests. If an armed force came to rob the carrier of his goods, he is liable; and the true reason is, for fear it may give room to collusion, that the master may contrive to be robbed on purpose, and share the spoil." In the early part of the present century, the law lapsed into a state of confusion by the efforts of carriers to limit their responsibility. They frequently attempted to do so by notices and advertisements, which were only effective so far as they could be brought home to the knowledge of the employer. To obviate the complex inquiries thus arising, the statute called the Carrier's Act, was passed in July 1830, "for the more effectual protection of mail contractors, stage coach proprietors, and other common carriers for hire" (1st Will. IV., cap. 68). It enumerates certain articles of a costly character, beginning with gold and silver, precious stones, jewellery, &c., for which the carrier is not to be responsible, except for the misconduct of himself and his servants, when parcels exceed the value of L.10, unless the nature of the contents have been imparted to him, and any additional charge as insurance premium demanded by him has been paid. It is a condition that a notice of the increased rate so chargeable must be publicly hung up in the carriers' office, and if it be not, he has no benefit from the act. At the same time, the act excludes all limitation of responsibility by mere notice or advertisement, except in the special cases of limitation for which it provides, leaving parties at liberty to make separate contracts. It is understood that canal companies are brought within this act by the 8th and 9th Vict., cap. 42, to enable canal companies to become carriers of goods on their canals. It does not apply to marine navigation; and for the special application of the principle to this great class of carriers the article Charter-party may be consulted. The peculiar statutory laws applicable to railway companies will be found under the head Railway; but here it may be noticed, that questions of considerable delicacy are opened by allowing railway companies the same power of specially stipulating for limited responsibility which belongs to ordinary carriers. The carrier in general has no monopoly, but competes with others; and if one refuse to take a particular risk, another may be found who will not decline it. The railway companies, however, which monopolize the means of transit over so great an area, by self-imposed limitations on their responsibility would virtually abrogate the law over the large districts to which their operations extend; and it becomes questionable how far on grounds of public policy they should possess such a privilege. The public attention was alarmingly directed to this point by an announcement that the directors of one company were determined to relieve themselves of responsibility for the personal safety of passengers conveyed on their line. (J. H. B.)

Carrier-*Pigeon* or *Courier-Pigeon*, a sort of pigeon which is trained to carry letters from one place to another. See Ornithology, *Columba*.

Though these birds be hood-winked, and carried 20, 30, or even 100 miles away, they will return in a very short space of time to the place where they were bred. They are trained to this service in Turkey and Persia; and are carried first, while young, short flights of half a mile, afterwards more, till at length they will return from the farthest part of the kingdom. Every pasha has a basket of these pigeons bred in the seraglio, which, upon any emergency, he despatches, with letters braced under the wings, to the seraglio. Lithgow affirms that one of these birds will carry a letter from Babylon to Aleppo, which is thirty days' journey, in forty-eight hours. The use of carrier-pigeons is very ancient. Hirtius and Brutus, at the siege of Mutina (Modena), maintained a correspondence with each other by means of pigeons. And Ovid relates that Taurosthenes gave notice to his father of his victory at the Olympic games by sending to him at Ægina a pigeon stained with purple.

Carron.

In modern times, the most noted were the pigeons of Aleppo, which served as couriers at Alexandretta and Baghdad. But this use of them was laid aside because the Kurd robbers killed the pigeons. The manner of sending advices by them was this: They took pairs which had young ones, and carried them on horseback to the place whence they wished them to return, taking care to let them have a full view. When the news arrived, the correspondent tied a billet to the pigeon's foot, and let her loose. The bird, impatient to see its young, flew off like lightning, and arrived at Aleppo in ten hours from Alexandretta, and in two days from Baghdad. The carrier-pigeon has nothing very peculiar in its form except its nostrils, which, instead of being smooth and even, are swelled and rough.

In this country there seem to be two other varieties of pigeon frequently used as messengers, namely, the *horseman* and *dragoon*. The following fact is related of the last-named variety:—A gentleman sent a dragoon by the stage-coach to a friend at St Edmund's Bury, along with a note, desiring that the bird, two days after its arrival there, might be thrown up into the air precisely as the town clock struck nine in the morning. This was accordingly done; and the pigeon was observed to fly into a loft in Bishopsgate Street, London, at half-past eleven of the same morning, having flown, probably without any violent exertion, 72 miles in two hours and a half.

Carrier-pigeons are still used to carry occasional despatches from the Bell Rock lighthouse to the northern shore of the Frith of Forth. They refuse, however, to leave the lighthouse during hazy weather; and as in this country considerable training seems necessary, the feats of these aerial messengers, though very admirable, are not so purely instinctive, and consequently not so unerring, as is usually supposed. Their use in obtaining intelligence of changes in the foreign stocks is well known.

CARRON, a small but remarkable river in Scotland, rising about the middle of the isthmus between the Friths of Forth and Clyde. Both its source, and the place where it empties itself into the sea, are within the shire of Stirling, which it divides into two nearly equal parts. The whole length of its course, which is from west to east, is not above fourteen miles. It falls into the Frith of Forth about three miles to the N.E. of Falkirk. The stream is small, and scarcely deserves the notice of a traveller; yet there is no river in Scotland, and few in the whole island of Britain, whose banks have been the scene of so many memorable transactions. When the Roman empire was in all its glory, and had its eastern frontiers upon the Euphrates, the banks of the Carron were its boundaries upon the N.W.; for the wall of Antoninus, which was raised to mark the limits of that mighty empire, stood in the neighbourhood of this river, and ran parallel to it for several miles.

From the valley of Dunipace the river runs for some time in a deep and hollow channel, with steep banks on both sides. Here it passes by the foundations of the ancient Roman bridge, not far from which, as is generally thought, was the scene of the memorable conference between the Scottish patriot William Wallace and Robert Bruce (father of the king of that name), which first opened the eyes of the latter to a just view both of his own true interest and that of his country.

After the river has left the village and bridge of Larbert it soon enters another smaller valley, through the midst of which it has now worn out to itself a straight channel; but in former ages it had taken a considerable sweep round, as appears by the track of the old bed, which is still visible.

The high and circling banks upon the south side give to this valley the appearance of a spacious bay; and, according to the tradition of the country, there was once a harbour here. Nor does the tradition seem altogether groundless—pieces of broken anchors having been found here, and some of them at no distant period. The stream-tides would still flow near the place if they were not kept back by the dam-head built across the river at Stenhouse; and there is reason to believe that the frith flowed considerably higher in former ages than it does at present. In the near neighbourhood of this valley, upon the south, stand the ruins of ancient Camelon, which after it was abandoned by the Romans was probably inhabited for some ages by the natives of the country.

Another ancient monument called *Arthur's Oven* once stood upon the banks of the Carron; but it has been entirely demolished. The corner of a small inclosure between Stenhouse and the Carron iron-works is pointed out as the place where it stood. This is generally supposed to have been a Roman work; though it is not easy to conceive what could be their motive for erecting such a fabric at so great a distance from any other of their works, and in a spot which at that time must have been very remote and unfrequented.

As the Carron extends over half of the isthmus, and runs so near the ancient boundaries of the Roman empire, the adjacent country naturally became the scene of many battles and rencounters. Historians mention a bloody battle fought near the river between the Romans and the confederate army of the Scots and Picts in the beginning of the fifth century. The scenes of some of Ossian's poems were, according to Macpherson, upon the banks of this river. About the distance of half a mile from the river, and near the town of Falkirk, is the field of battle where the English defeated Wallace in the year 1298. It goes by the name of *Graham's muir*, from the valiant Sir John Graham, who fell there, and whose gravestone is still to be seen in the churchyard of Falkirk.

Carron, a small village of Scotland, at which the celebrated iron-works are situated, lies in the parish of Larbert, on the northern bank of the river Carron, about two miles from Falkirk. These works belong to a chartered company established in 1760, with a capital of L.150,000, and afford employment to upwards of 2000 individuals.

CARRONADE, a short piece of ordnance, with a large calibre, and a chamber for the powder, like a mortar. It will throw a ball or a shell, and is very useful in close engagements at sea. This species of cannon takes its name from Carron, where it was first made, or the principle applied to an improved construction.

CARROT (*Daucus carota*, Lin.), a well-known biennial plant, a native of Britain. See Agriculture.

CARROUSAL, a course of chariots and horses, or a magnificent entertainment given by princes or other great personages, who, richly dressed and equipped after the manner of ancient cavaliers, and divided into squadrons, met in some public place to practise jousts, tournaments, and the like. The last carrousals in France were in the reign of Louis XIV. The word comes from the Italian word *carosello*, a diminutive of *carro* a chariot. Tertullian ascribes the invention of carrousals to Circe, and states that they were instituted in honour of the Sun, her father; whence some derive the word from *carrus*, or *carrus solis*. The Moors introduced ciphers, liveries, and other ornaments of arms, with trappings, &c., for their horses; and the Goths added crests, plumes, &c. See Tournament.

CARRUCA, in *Antiquity*, a splendid kind of car or chariot, mounted on four wheels, and richly decorated with gold, silver, ivory, &c., in which the emperors, senators, and people of rank were carried. The word comes from the Latin *carrus*, or British *car*

Carruca, or Caruca, is also used by writers of the middle ages to signify a plough, in French, *charrue*.

CARRUCATE (*carucata*), in our ancient laws, as much land as one team can plough in a year.

In Doomsday Inquisition the arable land is estimated in carrucates, the pasture in hides, and the meadow in acres. Skene makes the *carrucata* the same with *hilda* or *hida terræ*; Littleton, the same with soc.

In the reign of Richard I. a carrucate was estimated at sixty acres, and at one period of the same reign at a hundred acres; in the time of Edward I. it was rated at a hundred and eighty acres; and in the twenty-third of Edward III. a carrucate of land in Burcester contained a hundred and twelve acres, and in Middleton a hundred and fifty acres.

By a statute of William III., charging persons to repair the highways, a plough-land is rated at fifty pounds per annum, and may contain buildings, wood, pasture, &c.

CARRYING, in falconry, signifies a hawk's flying away with the quarry, instead of obeying the lure.

Carrying, among huntsmen, is when a hare runs on ground which sticks to her feet.

CARSE, a word signifying a flat piece of ground by a river, has been applied to three several tracts of country in Scotland, namely, the Carse of Falkirk, the Carse of Gowrie, and the Carse of Stirling.

CARSON, Aglionby Ross, M.A., LL.D., an eminent teacher and scholar, and for 25 years rector of the High School of Edinburgh, was born at Holywood in Dumfriesshire in 1778. He received the elements of his education at the Wallace Hall Academy, where he afterwards acted as assistant for two years. In 1801 he was elected to the rectorship of the Dumfries Grammar School, and in 1806 to a mastership in the High School of Edinburgh. When the rectorship of that latter seminary became vacant in 1820, it was conferred upon Mr Carson, who held it till his retirement in 1845. In 1826 his services to the cause of classical learning in Scotland were acknowledged by the University of St Andrews, which conferred upon him the degree of LL.D. His excellent editions of Phædrus, Tacitus, and other classics, are still extensively used in Scotland; but his most important work is his *Rules for the Construction of the Relative Qui, Quæ, Quod, established by a copious selection of Examples from Classical Authors;* a treatise to whose merits emphatic testimony has been borne by the most eminent scholars of the day. (See Dr Parr's works, vol. viii. pp. 533–54.) Dr Carson died in 1850.

CARSTAIRS or CARSTARES, William, an eminent Scottish divine, born at the village of Cathcart near Glasgow in 1649. He received the rudiments of his education at a school at Ormiston in East Lothian; but on commencing his studies for the church he removed to Edinburgh, and subsequently studied theology and philosophy at the University of Utrecht. While abroad he became acquainted with pensionary Fagel, and warmly espoused the interests of the Prince of Orange. On his return he became disheartened at the arbitrary proceedings of the Episcopal clergy, who were then high in the confidence of the king, and resolved immediately to retire to Holland; but he was speedily brought back to stand his trial on a charge of having been accessory to the Rye-house plot, and of being the medium of communication between the Presbyterian party in Scotland and the exiles in Holland. On manifesting great reluctance to divulge the nature of the correspondence with which he had been intrusted, he was put to the torture, but refused to make any disclosures until he had received the assurance that his replies should not be taken in evidence against himself or his compatriots. Having received the king's pardon, he was dismissed, and retired to Holland, where he rose still higher in the favour of the Prince of Orange. On King William's accession to the throne he

was appointed royal chaplain for Scotland, and contributed greatly to the firm establishment of the Presbyterian form of church government in that country. He still held his chaplaincy in the reign of Queen Anne; and while exercising considerable influence over the minds of the Scottish clergy in inducing them to approve of the Treaty of Union, he exerted himself strenuously to oppose the restoration of patronage in the church. In 1704 he was appointed principal and professor of divinity in the University of Edinburgh, in addition to the ministerial charge, first of the Greyfriars and afterwards of the High Church. He was four times chosen moderator of the General Assembly; and on the accession of George I. was sent on a deputation from the Assembly to congratulate the king. Carstairs died in 1715, and in 1744 was published the volume of *State Papers* from which he is chiefly known. They were edited by the Rev. Dr M'Cormick.

CART, a carriage with two wheels, drawn commonly by horses, and used to carry heavy goods, &c. The word seems formed from the French *charrette*, or the Latin *carreta*, a diminutive of *carrus*. See MECHANICS, *Wheel-carriages*.

CARTS *of War*, a peculiar kind of artillery anciently in use among the Scotch. In an act of parliament passed in 1456 they are thus described: "It is thought speidfull, that the king may requeist to certain of the great burrous of the land that are of ony myght, to mak carts of weir, and in ilk cart twa gunnis, and ilk ane to have twa chalmers, with the remnant of the graith that effeirs thereto, and an cunnand man to shut thame." By another act passed in 1471, the prelates and barons are commanded to provide such carts of war against their old enemies the English.

CARTE, THOMAS, an English historical writer, was the son of a clergyman, and was born at Clifton in Warwickshire in 1686. He took orders in 1713, but on the accession of George I. refused to take the oaths to government, and laid aside his clerical habit. From his open attachment to the house of Stuart he became obnoxious to government; and a reward of L.1000 having been offered for his apprehension, he fled to France, where he prepared an English translation of the works of De Thou. About 1703 he obtained permission to return to England, and began to write *The History of the Life of James, Duke of Ormonde, from his birth in* 1610, *to his death in* 1688. In 1744, when preparing to publish his *History of England*, he again fell under the suspicion of the government and was committed to prison, but was soon released. The last volume of his history did not appear till after his death, which took place in 1754.

CARTE-BLANCHE (French, white paper), a blank paper signed at the bottom with a person's name, and sometimes sealed with his seal, given to another person with power to superscribe what conditions he pleases.

CARTEL, a writing or agreement between two states for the exchange of prisoners of war. Cartel signifies also a letter of defiance or challenge to single combat. See DUEL.

CARTEL *Ship*, a ship employed in the exchange of prisoners, or in carrying propositions between belligerent powers. A cartel ship is allowed to carry no cargo, ammunition, or warlike implements, except one gun for firing signals.

CARTES, RÉNÉ DES, or DESCARTES, RÉNÉ, was born at La Haye, in Touraine, on the 31st of March 1596, and descended of a noble family, who came originally from Bretagne. In infancy his constitution was extremely delicate, or rather weak, a peculiarity which he shared in common with many other men of genius; and, in fact, it is sometimes in the feeblest body that the intellectual faculties exhibit the greatest vigour. He was educated among the Jesuits, then recently established in the college of La Flèche, and early distinguished himself by an extreme passion for study. It was at this seminary that he became first connected with Mersenne, afterwards a monk of the order of Minims, whose friendship was subsequently approved by its usefulness as well as fidelity to the illustrious object of it. Having completed the usual course of scholastic study, and of what was then as it is still in some parts of the world called *philosophy*, Descartes at once perceived the worthlessness of the acquisition he had made; but he was keenly alive to the interest and importance of the mathematical sciences, which nature had destined him to renovate. The first thing which he did on leaving college was, as he tells us in his Discourse on Method, to renounce all books, and to labour to efface from his mind every thing uncertain which he had learned, in order henceforward to admit nothing except what appeared to him to be demonstrated by reason and experience; and, in following out this mode of inquiry, he invented that method of sceptical examination which has since become the first principle of all our positive knowledge. At the present day we are unable to appreciate fully the greatness of such an effort, because we are educated in conformity with this very doctrine, which appears to us as natural as it is reasonable. But if we reflect that, at the period when Descartes lived, the Aristotelian philosophy exercised a despotic dominion over all minds, that it reigned supreme in the world as well as in the colleges, that it seemed a necessary support of religion, and that to doubt its truth was then considered as an act of unpardonable temerity, if not a crime, some conception may be formed of that force of mind which enabled a young man of nineteen to discard this intellectual idolatry, and to undertake the reformation of all his opinions. Nor is it less wonderful that at the period in question Descartes seems to have been in possession of his finest geometrical discoveries. This is sufficiently evinced by the history of his life; but the time had not yet arrived for the publication of his new ideas; and he thought that travelling, by extending his knowledge of mankind, would furnish him with favourable opportunities for improving himself in the only true philosophy.

Accordingly, he went abroad, and, conformably with his condition and the manners of his age, engaged in the profession of arms. He served successively as a volunteer in the army of Holland and in that of the Duke of Bavaria; and, in 1620, he was present at the battle of Prague. But although the ardour of youth led him then to take some pleasure in this tumultuous kind of life, he nevertheless knew how to appreciate rightly the bloody game of war; and seeking neither advancement nor fortune, he consented to take part in it only because it was necessary to accompany the men whom he wished to study closely. In the midst of camps he accordingly continued his metaphysical and mathematical speculations, and, as often as an occasion presented itself, put them to the test of experimental application. While he was in garrison at Breda, chance led him one day to a place where he observed on a wall a placard written in Flemish, with a number of persons assembled in a group before it, and containing the enunciation of a geometrical problem, which some unknown person proposed to mathematicians, according to the usage of the time. Not understanding Flemish, Descartes requested one of the spectators to explain the problem. The person to whom he applied was Beckman, principal of the college of Dort, and himself a mathematician, who, finding the problem very difficult, appeared surprised to see a young soldier inquiring about things of this sort, and, in answering him, assumed that air of pedantry and superiority which is common enough among his tribe; but his astonishment was extreme when the young soldier without hesitation promised a solution of the problem, and

actually transmitted it to him the following day.[1] For several years Descartes continued to lead this meditative and military life; but at length the reverses of which he was a witness in Hungary disgusted him with the profession of arms, which he therefore renounced, and continued his travels as a private individual. At this period an adventure happened to him which had nearly cost him his life. He had completed his travels through the north of Germany, and was returning to Holland by sea, when the crew of the vessel on board of which he had embarked, observing him to be of a quiet and gentle disposition, took him for a young man without experience, and concluded that it would be an easy matter to kill him, in order to take possession of his property, more especially as he was only attended by a single French domestic. Having come to this resolution, they held council together as to the means of executing their project; and they did not scruple to do so in the presence of their intended victim, under the impression that, being a foreigner, he would not understand them. But in this they were fortunately mistaken. Descartes had understood every word that passed, and when he was fully aware of their design, he started up suddenly, drew his sword, and addressing the ruffians in their own tongue, and in a determined manner, threatened to run them through if they dared to offer him the slightest insult. Intimidated by his boldness, the villains relinquished their purpose, and put him ashore in safety at the place where he wished to land. He then visited in succession Holland, France, Italy, Switzerland, the Tyrol, and ultimately spent some time at Venice and at Rome. Whilst in Italy, he did not visit Galileo, who had just entered upon the career of experimental philosophy; and, what is still more remarkable, he seems never to have entertained a proper sense of the merit of this great man; a circumstance which of itself would be sufficient to prove that Descartes, although admirable as a geometrician, was ignorant of the true method by which alone the physical sciences can be advanced.

Having returned from his travels, and taken a survey of the various occupations of men, Descartes perceived that the only one which suited him was the cultivation of reason; but as his ardent temperament naturally led him into extremes, he conceived a notion that, if he remained in France, he would neither be sufficiently solitary nor sufficiently free for the prosecution of the pursuits in which he was anxious to engage. Accordingly, having sold part of his property, he, in 1629, retired into Holland, which he regarded as a tranquil retreat, peculiarly suitable for peaceful and free meditation; and there applied himself to the study of metaphysics, anatomy, chemistry, and astronomy. He composed a treatise on the System of the World, such as he then conceived it; but on the news of the imprisonment of Galileo, he suppressed this production; and it was probably the dread of similar persecution which caused him, at a later period, to adopt the improbable and absurd notion of the sun and the planets revolving round the earth, as Tycho Brahe had done before him. As yet Descartes had published no mathematical work of any extent; but his genius for the exact sciences, and his immense superiority over the greater part of his contemporaries, were already evinced by the extreme facility with which he resolved, almost in sport, the questions which appeared to them the most difficult. The vivacity of his character involved him in quarrels with some of them; and in these he was sometimes in the right, sometimes in the wrong. He was in the right with Roberval, a French mathematician, who, denying his genius, laboured long to represent him as a vile plagiary of the discoveries of others; but he was in the wrong with regard to Fermat, to whom he did not at first do full justice, and who, though able to maintain a contest on equal terms, was ever desirous to render homage to the genius of Descartes, and to seek his friendship. At length, yielding to the solicitations of his friends, and probably influenced by an honourable desire to shut the mouths of his adversaries, Descartes consented to publish his discoveries. But attaching more value to metaphysical speculations, to which he had then devoted himself, than to the geometrical methods of which he was the inventor, and which had already perhaps lost the charm of novelty, he gave his geometry only as a single chapter of his Treatise on Method, and this chapter was worked up slightly and in haste. Posterity, however, has reversed this judgment, and regarded the geometrical labours of Descartes as affording the best proofs of his genius. Before his time considerable progress had been made in researches purely algebraic, and the resolution of equations of the second, third, and fourth order had already been invented; but the notation employed was still rude, and affected by material relations, which intermixed with algebra, strictly so called, ideas of length, of surface, and of solidity. Algebra, however, is a language the special object as well as the principal advantage of which is to express only the abstract relations of quantities. To extend it, therefore, it is necessary to begin by freeing it from all foreign considerations or elements by which it is limited. Descartes was the first who rendered it this important service; for the metaphysical bent of his mind, which was injurious to him in the sciences of application, proved singularly useful in this particular. According to the ancient limitation of algebra, the successive products of the same quantity were represented in the three first dimensions by a square and a cube in perspective, sometimes by the initial letter of the word "square" or the word "cube" placed above the quantity, and sometimes by the repetition of the letter by means of which the quantity was designated. For this embarrassing mode of notation, which impeded the current of thought, Descartes substituted one clear, simple, general, and, above all, adapted to the purposes of calculation. He placed a cipher above the quantity, and by its different values he indicated the different powers of that quantity. But his greatest discovery consisted in the application of algebra to geometry. He imagined that the nature of each curve might be expressed and defined by a certain relation between two variable lines, of which one represented the absciss and the other the ordinate; and he conceived that, in order to find this relation, it would be sufficient to express in algebraic language one of the characteristic properties of the curve, as, for instance, of the circle, which is a plane curve, all the points of which are equidistant from a given point called the centre. And this discovery had the inestimable advantage, that being once translated into a formula, all that remained to be done was to consider in an abstract manner the resultant equation, in order to deduce from it the other geometrical properties involved in the primary definition.

Descartes, however, did not stop here; but, pursuing his investigations, he made a discovery exactly the inverse of the preceding. Having learned to express and to know the properties of curves by algebraic equations, he no longer

[1] It was during his stay at Breda that Descartes composed his *Compendium Musicæ*, which was not printed till after his death. (Utrecht, 1650, 4to.) A French translation by Father Poisson, of the Oratory, will be found at the end of the *Méchanique* of Descartes. Paris, 1668, 4to.

regarded these equations, except as emblems of curves intersected so that the abscisses formed the roots of the equations; and, once in possession of these general methods, he was enabled to enunciate in algebraic language, and to resolve directly, geometrical problems which had baffled all antiquity. This he himself exemplified in the very first question of his geometry; and it is easy to conceive how, possessed of this secret, he was enabled to disport with the greater part of the questions which puzzled the mathematicians of his age. His geometry, at the time when it appeared, was found exceedingly difficult to read; and he himself tells us that he had not sought to develop the different steps of procedure by which he arrived at his results; but at the present day his methods are the first which are taught to youth, and for this reason they appear to us much more easy. In a word, the treatise on geometry does honour to the genius of Descartes, and forms one of his proudest titles to immortality.

His Discourse on Dioptrics also contains many ingenious geometrical applications; but whilst the unequal refrangibility of the different rays of light was unknown, it was impossible that any available progress could be made in this branch of science. Nevertheless it contains another proof of the genius of Descartes in the discovery therein made of the true law of refraction; a discovery which was contested by Huygens after his death, but which, notwithstanding the pretensions of that philosopher, unquestionably belongs to him. The Treatise on Meteors, which is also contained in his Discourse on Method, is much more imperfect than his Dioptrics, inasmuch as he gives rein to his imagination, and undertakes to explain all meteorological phenomena, including even the formation of lightning. It is, however, distinguished by a discovery; for he has given the true theory of the rainbow, as far as it was possible to do so at a period when the unequal refrangibility of light was altogether unknown. His *Principia*, or Principles of Philosophy, were first published in 1644, at the age of forty-nine. This work is divided into four parts; the first, devoted to rational philosophy or metaphysics, contains an exposition of the principles of all human knowledge; the second treats of the principles of natural things; and the last two develop his theory of the system of the world, the once celebrated, but, since the time of Newton, for ever exploded theory of vortices. We abstain from making any observations either as to the metaphysical notions or physical theories of Descartes, both of which have been treated of with consummate ability and sufficient amplitude of detail in the Dissertations prefixed to this work. With regard to the former, we shall merely add, that in his celebrated Discourse on the Method of conducting the Reason, and seeking Truth in the Sciences, published in 1637, Descartes had already made known the principal points of his doctrine, and broached the most abstract questions of metaphysics. These, however, he had treated with greater order and fulness in the not less celebrated work which he published in 1641, three years before his *Principia*, entitled "Meditations concerning the first Philosophy, in which are demonstrated the Existence of God, and the Immortality of the Soul." These Meditations are six in number, forming a book small in itself, but which was considerably enlarged by the objections of several metaphysicians of the time, among whom may be mentioned Arnauld, Gassendi, and Hobbes, and by the answers which Descartes made to these objections. They were originally published in Latin; but, in 1642, the Duke of Luynes translated the Meditations, and Clerselier the Objections and Answers, into French.

The influence which Descartes exercised over his age was very great indeed; his fame spread rapidly, and soon became all but universal. In France, particularly, the novelty of his hypotheses, the grandeur and boldness of his views, and the apparent generality of his methods, swayed more or less the most cultivated minds of the age of Louis XIV. It has been remarked that his partizans were for the most part of the number of those who professed the most independent ideas. Bossuet and Fenelon, Malebranche and the principal members of the congregation of the Oratory, and almost all the writers of the celebrated school of Port-Royal, adopted Cartesianism; and from the same source Pascal derived that spirit of discussion which distinguishes the Provincial Letters. The Jesuits were later in giving in their adherence to the dominant philosophy; and the University admitted it still more reluctantly, and only as it were at the last extremity. But in its transmission the metaphysical doctrine of Descartes experienced the fate which must ever attend all systems of dogmatic philosophy. In adopting it, each modified it according to the bent of his own mind, or the cast of his own character; receiving or rejecting as much of it as suited his convenience, and deducing from it consequences which, in their turn, formed the basis of new systems. Hence the most opposite, not to say contradictory theories, all acknowledged Cartesianism as their common source. From it Malebranche derived his mystical spiritualism, and Berkeley his pure idealism; Spinosa found in it the germ of what has been called his materialism; and the greater part of the schools of philosophy which have succeeded each other in Germany since the time of Descartes, may be considered as originating in the same common source.

The writings of Descartes involved him in controversy, and exposed him to persecution. His disputes with Roberval and Fermat have been already noticed by us when adverting to his geometrical investigations and discoveries. But controversies purely scientific are seldom pursued with exasperation, or calculated to mar the happiness of life; and, in point of fact, if Descartes was misrepresented by Roberval, he was guilty of injustice to Fermat. In the hazy region of metaphysics, however, where it is equally difficult to attain any measure of certainty, and easy to discover pretexts for accusations of error or heresy, the most violent contentions are commonly engendered, and men's passions become excited and envenomed from the very cause which ought to beget charity and forbearance. And so it proved in the case of Descartes. To his metaphysical writings he owed all the disputes which served to disturb the tranquillity of his life; and amongst the clergy he found the bitterest enemies and persecutors. Of the latter, by far the most inveterate was Gisbert Voet, primarius professor of theology in the university of Utrecht; a man whose respectable station and austere manners had secured him a degree of credit much beyond what was due to his ability or learning, and who felt no compunction in accusing of atheism a philosopher who had exhausted all the resources of his genius to discover new demonstrations of the existence of God. But when hatred addresses itself to credulity, it is almost certain to triumph. The fierce theologian of Utrecht attempted in vain to engage Father Mersenne, the intimate and much-loved friend of Descartes, to write publicly against him in defence of the Catholic religion; but though deceived in his expectation of enlisting Mersenne as an auxiliary, he did not relinquish his design; and by continued solicitations and manœuvres he at length succeeded in "impetrating" a sentence against Descartes, condemning him to pay a very considerable fine, and ordaining his works to be burned. Voet is said to have assisted the executioner in carrying into effect the latter part of the sentence. The theologians of Leyden, imitating the example of those of Utrecht, soon stirred up a new persecution against the philosopher; who, harass-

Cartes, René des || Carthage.

ed and vexed by these annoyances, cursed the celebrity he had acquired, and regretting the sweets of his retired and studious life, took as his device *Qui bene latuit, bene vixit.*

Whilst he was in this mood of mind, Descartes received an invitation from Christina, queen of Sweden, to repair to the court of that country, where he was promised an asylum and protection. Although he had always loved independence, and valued his liberty so highly that, as he said, no prince on earth could induce him to surrender it, yet he accepted this proposal, as indeed he had every reason to do. It was made to him at a moment when he was unhappy; whilst the honour of being sought after by a great queen, and called to her presence and society, was calculated to be useful in enabling him to confound his persecutors. He determined therefore to quit his hermitage at Egmont, in order to repair to Sweden and pass his days in the rigorous climate of that country. On his arrival at court, he was received with the greatest distinction by the queen, and obtained, at his own solicitation, the favour of being exempted from all observance of ceremony, and of only appearing at court when he was specially called. But as the price of this dispensation, the queen stipulated that he would come to converse with her every morning at five o'clock in her library. Descartes, however, who always needed repose, and whose health required great attention, was unable to bear up under the change of life which this matutinal duty imposed on him, especially in so cold a climate, and during the rigour of winter. He was attacked by a disease in the chest, accompanied with delirium, and expired on the 11th February 1650, at the comparatively early age of fifty-four. The queen wished his remains to be interred amongst those of the first families of Sweden; but the ambassador of France interposed, and his corpse was conveyed to Paris for sepulture among his countrymen.

Cartesian || Carthage.

The works of Descartes have been collected under the title of *Opera Omnia*, Amsterdam, 1690–1701, 9 vols. 4to, or 1713, also 9 vols. The French edition consists of 13 vols. 12mo, containing, 1. Les Principes de la Philosophie, écrits en Latin par Descartes, et traduits en Français par un de ses Amies (Picot), 1724; 2. L'Homme de René Descartes, et la Formation du Fœtus, avec les Rémarques de Louis de Laforge, 1729; 3. Méditations Métaphysiques, 1724; 4. Les Passions de l'Ame, le Monde, ou Traité de la Lumière, et la Géométrie, &c. 1726; 5. Discours de la Méthode, &c. la Dioptrique et les Météores, la Mécanique et la Musique, 1724; 6. Lettres, 1724–1725; together with Bayle's Recueil de quelques Piéces curieuses concernant la Philosophie de Descartes, 1684. (See *Biographie Universelle*, art. DESCARTES.) (J. B—E.)

CARTESIANS, a sect of philosophers, who adhered to the system of Descartes, founded on two principles, the one metaphysical, the other physical. The metaphysical principle is, *I think, therefore I am;* the physical principle is, that *nothing exists but substance.* Descartes considered substances as of two kinds; the one a substance that thinks, the other a substance extended; and hence actual thought and actual extension are, according to him, the essence of substance. The essence of matter being thus fixed in extension, the Cartesians conclude that there is no vacuum, nor any possibility of one, in nature, and that the universe is absolutely full. Mere space is excluded by this principle, because extension being implied in the idea of space, matter is so too. Upon these principles the Cartesians endeavoured to explain mechanically the formation of the world, and to account for the celestial phenomena.

CARTHAGE,

A FAMOUS city of antiquity, the capital of *Africa Propria,* which for many years disputed with Rome the sovereignty of the world. According to Velleius Paterculus, this city was built 65, according to Justin and Trogus 72, according to others 100 or 140 years, before the foundation of Rome. It is agreed on all hands that the Phœnicians were the founders.

History.

The beginning of the Carthaginian history, like that of all other nations, is obscure and uncertain. In the seventh year of Pygmalion, king of Tyre, his sister Elisa, or Dido, is said to have fled, with some of her companions and vassals, from the cruelty and avarice of her brother, who had put to death her husband Sichæus in order to obtain possession of his wealth. She first touched at the island of Cyprus, where she met with a priest of Jupiter, who expressed a desire of attending her; a proposal to which she readily consented, and fixed the priesthood in his family. At that time it was a custom in the island of Cyprus for the young women to go on certain stated days, before marriage, to the sea side, there to look for the arrival of strangers on their coasts, in order to prostitute themselves for gain, that they might thereby acquire a dowry. Of these strange damsels the Tyrians selected eighty, whom they carried along with them. From Cyprus they sailed directly for the coast of Africa; and at last landed safely in the province called *Africa Propria,* not far from Utica, a Phœnician city of great antiquity. The inhabitants received their countrymen with great demonstrations of joy, and invited them to settle in the country. The common fable is, that the Phœnicians imposed upon the Africans. They desired for their intended settlement only as much ground as an ox's hide would encompass. This request the Africans laughed at; but they were surprised when, upon their granting it, they saw Elisa cut the hide into the smallest shreds, by which means it surrounded a large territory, in which she built the citadel called *Byrsa.* The learned, however, are now unanimous in exploding this fable; and it is certain that the Carthaginians for many years paid an annual tribute to the Africans for the ground they occupied.

Byrsa.

The new city soon became populous and flourishing by the accession of the neighbouring Africans, who resorted thither at first with a view of traffic. In a short time it became so considerable, that Jarbas, a neighbouring prince, thought of making himself master of it without any effusion of blood. To effect this, he desired that an embassy of ten of the most noble Carthaginians might be sent to him; and, upon their arrival, he proposed to them a marriage with Dido, threatening war in the event of refusal. The ambassadors, being afraid to deliver this message, told the queen that Jarbas desired some person might be sent to him who was capable of civilizing his Africans, but that there was no possibility of finding any of her subjects who would leave his relations for the conversion of such barbarians. For this they were reprimanded by the queen, who told them that they ought to be ashamed of refusing to live in any manner for the benefit of their country; upon which they informed her of the true nature of their message from Jarbas, adding that, according to her own decision, she ought to sacrifice herself for the good of her country. The unhappy queen, rather than submit to be the wife of such a barbarian, caused a funeral pile to be erected, and put

Carthage.

Dido kills herself.

an end to her life with a dagger. This is Justin's account of the death of Queen Dido; as to Virgil's story of her amour with Æneas, it is obviously fabulous, and was so considered even in the days of Macrobius.

How long monarchical government continued in Carthage, or what happened to this state in its infancy, we are altogether ignorant, by reason of the Punic archives having been destroyed by the Romans; so that there is a chasm in the Carthaginian history for above 300 years. It appears, however, that from the very beginning the Carthaginians applied themselves to maritime affairs, and were formidable by sea in the time of Cyrus and Cambyses. From Diodorus Siculus and Justin it appears that the principal support of the Carthaginians were the mines of Spain, in which country they seem to have very early established themselves; and by means of the riches drawn from these mines they were enabled to equip the formidable fleets which they are said to have fitted out in the time of Cyrus or Cambyses. Justin insinuates that the first Carthaginian settlement in Spain happened when the city of Gades, now Cadiz, was only in its infancy. The Spaniards finding this new colony beginning to flourish, attacked it with a numerous army, insomuch that the inhabitants were obliged to call to their aid the Carthaginians, who very readily granted their request, and not only repulsed the Spaniards, but made themselves masters of almost the whole province in which their new city stood. By this success they were encouraged to attempt the conquest of the whole country; but having to deal with very warlike nations, they could not push their conquests to any great length at first; and it appears from the accounts of Livy and Polybius, that the greater part of Spain remained unsubdued till the time of Hamilcar, Asdrubal, and Hannibal.

First treaty with Rome.

About 503 years before the birth of Christ the Carthaginians entered into a treaty with the Romans. It related chiefly to matters of navigation and commerce. From it we learn that the whole island of Sardinia, and part of Sicily, were then subject to Carthage; that the Carthaginians were very well acquainted with the coasts of Italy, and had previously made some attempts upon them; and that, even at this early period, a spirit of jealousy had been excited between the two republics.

Sicily invaded.

By degrees the Carthaginians extended their power over all the islands in the Mediterranean, Sicily excepted; and for the entire conquest of this island they made vast preparations about 480 years before Christ. Their army consisted of 300,000 men; their fleet was composed of upwards of 2000 men of war and 3000 transports; and with such an immense armament they made no doubt of conquering the whole island in a single campaign. In this, however, they found themselves miserably deceived. Hamilcar their general having landed his numerous forces, invested Himera, a city of considerable importance, and carried on his approaches with the greatest assiduity; but he was at last attacked in his trenches by Gelon and Theron, the tyrants of Syracuse and Agrigentum, who inflicted on the Carthaginians one of the greatest overthrows mentioned in history. A hundred and fifty thousand were killed in the battle and pursuit, and all the rest taken prisoners, so that of so mighty an army not a single individual escaped. Of the 2000 ships of war and 3000 transports of which the Carthaginian fleet consisted, eight ships only, which happened to be out at sea, made their escape, and immediately set sail for Carthage; but these were all cast away, and every soul perished, except a few who were saved in a small boat, and at last reached Carthage with the dismal news of the total loss of the fleet and army. No words can express the consternation of the Carthaginians upon receiving the news of so terrible a disaster. Ambassadors being immediately dispatched to Sicily, with orders to conclude a peace upon any terms, they put to sea without delay, and landing at Syracuse, threw themselves at the conqueror's feet, begging Gelon, with many tears, to receive their city into favour, and grant them a peace on whatever conditions he should choose to prescribe. Gelon granted their request, upon condition that Carthage should pay him 2000 talents of silver to defray the expenses of the war; that they should build two temples, in which the articles of the treaty might be lodged and kept as sacred; and that for the future they should wholly abstain from human sacrifices. This peace, for which there existed so much necessity, was not thought too dearly purchased; and to show their gratitude for Gelon's moderation, the Carthaginians complimented his wife Demerata with a crown of gold worth a hundred talents.

From this time we find little mention of the Carthaginians for seventy years. During the latter period, however, they greatly extended their dominions in Africa, and likewise shook off the tribute which gave them so much uneasiness. They had also warm disputes with the inhabitants of Cyrene, the capital of Cyrenaica, about a regulation of the limits of their respective territories. The consequence of these disputes was a war, which reduced both nations so low that they consented first to a cessation of hostilities, and then to a peace. At last it was agreed that each state should appoint two commissioners, who should set out from their respective cities on the same day, and that the spot on which they met should be the boundary of both states. In consequence of this, two brothers called Philæni were sent out from Carthage, and advanced with great celerity, whilst those from Cyrene were much slower in their motions. Whether this proceeded from accident, or design, or perfidy, we are not certainly informed; but the Cyreneans, finding themselves greatly outstripped by the Philæni, accused them of breach of faith, asserting that they had set out before the time appointed, and consequently that the convention between their principals was broken. The Philæni desired them to propose some expedient by which their differences might be accommodated, promising to submit to it, whatever it might be. The Cyreneans then proposed, either that the Philæni should retire from the place where they were, or that they should be buried alive upon the spot. With this last condition the brothers immediately complied, and by their death gained a large extent of territory to their country. The Carthaginians ever afterwards celebrated this as a most brave and heroic action, paid the brothers divine honours, and endeavoured to immortalize their names by erecting two altars there, with suitable inscriptions upon them.

Dispute with the Cyreneans.

Sicily again invaded.

About the year before Christ 412, some disputes happening between the Egestines and Selinuntines, inhabitants of two cities in Sicily, the former called in the Carthaginians to their assistance, and occasioned a new invasion of Sicily by that nation. Great preparations were made for this war; and Hannibal, whom they had appointed as general, was empowered to raise an army equal to the undertaking, as well as equip a suitable fleet. They also appropriated certain funds for defraying the expenses of the war, intending to exert their whole force to reduce the island under subjection.

The Carthaginian general having landed his forces, immediately marched for Selinus. In his way he took Emporium, a town situated on the river Mazara; and having arrived at Selinus he immediately invested it. The besieged made a very vigorous defence; but at last the city was taken by storm, and the inhabitants were treated with the utmost cruelty. All were massacred by the savage con-

Carthage. queror, except the women who fled to the temples; and these escaped, not through the merciful disposition of the Carthaginians, but because it was feared that, if driven to despair, they would set fire to the temples, and by that means consume the treasure they expected to find in these places. Sixteen thousand were massacred; 2250 escaped to Agrigentum; and the women and children, about 5000 in number, were carried away into captivity. At the same time the temples were plundered, and the city razed to the ground. After the reduction of Selinus Hannibal laid siege to Himera, a city which he desired above all things to become master of, in order that he might revenge the death of his grandfather Hamilcar, who had been slain before it by Gelon. His troops, flushed with their late success, behaved with undaunted courage; but finding that his battering engines did not answer his purpose sufficiently, he undermined the wall, supporting it with large beams of timber, to which he afterwards set fire, and thus laid part of it flat on the ground. Notwithstanding this advantage, however, the Carthaginians were several times repulsed with great slaughter; but at last they became masters of the place, and treated it in the same manner as they had done Selinus. After this, Hannibal, dismissing his Sicilian and Italian allies, returned to Africa.

The Carthaginians were now so much elated that they meditated the reduction of the whole island. But as the age and infirmities of Hannibal rendered him incapable of commanding the forces alone, they joined in commission with him Imilcar, the son of Hanno, one of the same family. On the landing of the Carthaginian army, all Sicily was alarmed, and the principal cities put themselves into the best state of defence they were able. The Carthaginians immediately marched to Agrigentum, and began to batter the walls with great fury. The besieged, however, defended themselves with incredible resolution, burnt in a sally all the machines raised against their city, and repulsed the enemy with great slaughter. In the mean time, the Syracusans, alarmed at the danger of Agrigentum, sent an army to its relief. On their approach they were immediately attacked by the Carthaginians; but after a sharp contest the latter were defeated, and forced to fly to the very walls of Agrigentum, with the loss of about 6000 men. Had the Agrigentine commanders now sallied out and fallen upon the fugitives, the Carthaginian army must in all probability have been destroyed; but, either through fear or corruption, they refused to stir out of the place, and this occasioned its fall. Immense booty was found in the city; and the Carthaginians behaved with their usual cruelty, putting all the inhabitants to the sword, not excepting those who had fled to the temples.

The next attempt of the Carthaginians was intended to be against the city of Gela; but the Geleans, being greatly alarmed, implored the protection of Syracuse; and, at their request, Dionysius was sent to assist them with 2000 foot and 400 horse. The Geleans were so well satisfied with his conduct, that they treated him with the highest marks of distinction; they even sent ambassadors to Syracuse to return thanks for the important services done them by sending him thither; and soon afterwards he was appointed generalissimo of the Syracusan forces and those of their allies, against the Carthaginians. In the mean time, Imilcar, having razed the city of Agrigentum, made an incursion into the territories of Gela and Camarina, which he ravaged in a dreadful manner, carrying off an immense quantity of plunder, which filled his whole camp. He then marched against the city; but though it was indifferently fortified, he met with a vigorous resistance, and the place held out for a long time without receiving any assistance from its allies. At last Dionysius came to its relief with an army of 50,000 foot and 1000 horse. At the head of this body he attacked the Carthaginian camp, but was repulsed with great loss; upon which he called a council of war, the result of whose deliberations was, that since the enemy was so much superior to them in strength, it would be highly imprudent to put all to the issue of a battle, and that the inhabitants should therefore be persuaded to abandon the country, as the only means of saving their lives. A trumpet was accordingly sent to Imilcar to desire a cessation of hostilities until the next day, in order, as was pretended, to bury the dead, but in reality to give the people of Gela an opportunity of making their escape. About the beginning of the night the greater part of the citizens left the place; and Dionysius himself with the army followed them about midnight. To amuse the enemy, he left 2000 of his light-armed troops behind him, commanding them to make fires all night, and set up loud shouts, as though the army still remained in the town. But at day-break this body took the same route as their companions, and pursued their march with great celerity. The Carthaginians, finding the city deserted by almost all its inhabitants, immediately entered it, putting to death such as remained; after which Imilcar, having thoroughly plundered it, moved towards Camarina. The inhabitants of this city had been likewise drawn off by Dionysius, and it underwent the same fate with Gela.

Notwithstanding these successes, however, Imilcar finding his army greatly weakened, partly by the casualties of war, and partly by a plague which broke out in it, sent a herald to Syracuse to offer terms of peace. His unexpected arrival was very agreeable to the Syracusans, and a peace was immediately concluded, upon the conditions that the Carthaginians, besides their ancient acquisitions in Sicily, should still possess the countries of the Silicani, the Selinuntines, the Himereans, and Agrigentines; that the people of Gela and Camarina should be permitted to reside in their respective cities, which, however, were to be dismantled, upon their paying an annual tribute to the Carthaginians; and that all the Sicilians should preserve their independence, except the Syracusans, who were to continue in subjection to Dionysius.

Carthaginians attacked by Dionysius.

The tyrant of Syracuse, however, had concluded this peace with no other view than to gain time, and to put himself in condition to attack the Carthaginian territories at greater advantage. Having accomplished his object, he acquainted the Syracusans with his design, and they immediately approved of it; upon which he gave up to the fury of the populace the persons and possessions of the Carthaginians who resided in Syracuse, and traded there, relying on the faith of treaties. As there were at that time many of their ships in the harbour, laden with cargoes of great value, the people immediately plundered them, and, not content with this, ransacked their houses in a most outrageous manner. This example was followed throughout the whole island; and in the mean time Dionysius dispatched a herald to Carthage, with a letter to the senate and people, telling them, that if they did not immediately withdraw their garrisons from all the Greek cities in Sicily, the people of Syracuse would treat them as enemies. With this demand, however, he did not allow them time to comply; for, without waiting for any answer from Carthage, he advanced with his army to Mount Eryx, near which stood the city of Motya, a Carthaginian colony of great importance, which he immediately invested. But soon afterwards, leaving his brother Leptines to carry on the attack, he proceeded with the greater part of his forces to reduce the cities in alliance with the Carthaginians. He destroyed their territories with fire and sword, levelled all their trees, and then invested Egesta and Entella, most of the other towns having opened their gates at his approach; but these having baffled his utmost efforts, he returned to

Carthage.

Motya, and pushed on the siege of that place with the utmost vigour. The Carthaginians, in the mean time, though alarmed at the message sent them by Dionysius, and reduced to a miserable condition by the plague, which had broken out in their city, did not despond, but dispatched officers to Europe, with considerable sums, to raise troops with the utmost diligence. Ten galleys were also sent from Carthage to destroy all the ships that might be found in the harbour of Syracuse. The admiral, according to his orders, entered the harbour during the night, without being discerned by the enemy; and having sunk most of the ships he found there, returned without the loss of a man. Meantime the Motyans defended themselves with incredible vigour; whilst their enemies, desirous of revenging the cruelties exercised upon their countrymen by the Carthaginians, fought like lions. At last the place was taken by storm, and the Greek soldiers began a general massacre, which Dionysius was for some time unable to restrain; but at last he ordered the Motyans to fly to the Greek temples, which they accordingly did, and a stop was thus put to the slaughter. The soldiers, however, took care thoroughly to plunder the town, in which they found great treasure.

The following spring Dionysius invaded the Carthaginian territories, and made an attempt upon Egesta; but here he was again disappointed. The Carthaginians were greatly alarmed at his progress; but next year, notwithstanding a considerable loss sustained in a sea-fight with Leptines, Himilco their general landed a powerful army at Panormus, seized upon Eryx, and then advancing towards Motya, made himself master of it before Dionysius could send any forces to its relief. He next proceeded to Messana, which he likewise besieged and took; after which most of the Siculi revolted from Dionysius.

Greeks defeated at sea.

Notwithstanding this defection, Dionysius, finding that his forces still amounted to 30,000 foot and 3000 horse, advanced against the enemy. At the same time Leptines was sent with the Syracusan fleet against that of the Carthaginians, but with positive orders not to break the line of battle upon any account whatsoever. Notwithstanding these orders, he thought proper to divide his fleet, and the consequence was that he suffered a total defeat, above 100 of the Syracusan galleys being sunk or taken, and 20,000 men killed either in the battle or in the pursuit. Dionysius, disheartened by this misfortune, returned with his army to Syracuse, being afraid that the Carthaginian fleet might become masters of that city if he advanced to fight the army. On the other hand, Himilco did not fail immediately to invest the capital; and would certainly have become master of it, and consequently of the whole island, had not a most malignant pestilence obliged him to desist from all further operations. This dreadful malady made great havock among his forces both by land and sea; and, to complete his misfortunes, Dionysius attacked him unexpectedly, totally ruined his fleet, and made himself master of his camp.

Syracuse besieged.

Himilco obliged to return.

Himilco, finding himself altogether unable to sustain another attack, was obliged to come to a private agreement with Dionysius, who for three hundred talents consented to permit him to escape to Africa with the shattered remains of his fleet and army. The unfortunate general arrived at Carthage clad in mean and sordid attire, where he was met by a great number of people bewailing their sad and inauspicious fortune. Himilco joined them in their lamentations; and, being unable to survive his misfortunes, put an end to his own life. Having left Mago in Sicily to take care of the Carthaginian interests in the best manner he could, this person treated all the Sicilians subject to Carthage with the greatest humanity; and, having received a considerable number of soldiers from Africa, he at last formed an army, with which he ventured a battle. But in this he was defeated, and driven out of the field, with the loss of 800 men; which obliged him to desist from further attempts of that nature.

Another invasion of Sicily.

Notwithstanding these terrible disasters, the Carthaginians could not refrain from making new attempts upon the island of Sicily, and about the year before Christ 392 Mago landed in it with an army of 80,000 men. This attempt, however, was attended with no better success than the former ones; and Dionysius found means to reduce him to such straits for want of provisions, that he was obliged to sue for peace, which lasted nine years. At the end of this period the war was renewed with various success, and continued with little interruption till the year before Christ 376, when the Syracusan state being rent by civil dissensions, the Carthaginians thought it a proper time to exert themselves, in order to become masters of the whole island. They fitted out a great fleet, and entered into alliance with Icetas, tyrant of the Leontini, who pretended to have taken Syracuse under his protection. By this treaty the two powers engaged to assist each other in order to expel Dionysius II.; after which they were to divide the island between them. The Syracusans applied for succours to the Corinthians, who readily sent them a body of troops under the command of Timoleon, an experienced general. By a stratagem this commander succeeded in landing his forces at Taurominium. The whole of them did not exceed 1200 in number; yet with these he marched against Icetas, who was at the head of 5000 men, surprised his army at supper, put 300 of them to the sword, and took 600 prisoners. Then marching to Syracuse, he penetrated into one part of the town before the enemy had any notice of his approach. Here he took post, and defended himself with such resolution, that he could not be dislodged by the united power of Icetas and the Carthaginians.

In this place he remained for some time in expectation of a reinforcement from Corinth, till the arrival of which he did not judge it practicable to extend his conquests. But the Carthaginians, being apprised that the Corinthian succours were detained by tempestuous weather at Thurium, posted a strong squadron, under Hanno their admiral, to intercept them in their passage to Sicily. That commander, however, not imagining the Corinthians would attempt a passage to Sicily in such a stormy season, left his station at Thurium, and ordering his seamen to crown themselves with garlands, and adorn their vessels with bucklers of both the Greek and Carthaginian form, sailed to Syracuse in a triumphant manner. Upon his arrival there, he gave the troops in the citadel to understand that he had taken the succours Timoleon expected, thinking by this means to intimidate them into a surrender. But while he thus trifled away his time, the Corinthians marched with great expedition to Rhegium, and, taking the advantage of a gentle breeze, crossed over into Sicily. Mago, the Carthaginian general, no sooner received information of the arrival of this reinforcement, than he was struck with terror; and though the whole Corinthian army did not exceed 4000 men, he soon afterwards weighed anchor, in spite of all the remonstrances of Icetas, and set sail for Africa. But he no sooner arrived, than, overcome with remorse and shame for his unparalleled cowardice, he laid violent hands on himself. His body was hung upon a gallows or cross, in order to deter succeeding generals from forfeiting their honour in so flagrant a manner.

Exploits of Timoleon.

After the flight of Mago, Timoleon carried all before him. He obliged Icetas to renounce his alliance with the state of Carthage, nay even deposed him, and continued his military preparations with the greatest vigour. On the other hand, the Carthaginians prepared for the ensuing campaign with the utmost alacrity. An army of

70,000 men was sent over, with a fleet of 200 ships of war and 1000 transports laden with warlike engines, armed chariots, horses, and all other sorts of provisions. This immense multitude, however, was overthrown on the banks of the Crimesus by Timoleon; 10,000 were left dead on the field of battle, and of these more than 3000 were native Carthaginians of the best families in the city. Above 15,000 were taken prisoners; and all their baggage and provisions, with 200 chariots, 1000 coats of mail, and 10,000 shields, fell into Timoleon's hands. The spoil, which consisted chiefly of gold and silver, was so immense that the whole Sicilian army was occupied three days in collecting it and stripping the slain. After this signal victory, he left his mercenary forces upon the frontiers of the enemy, in order to plunder and ravage the country; whilst he himself returned to Syracuse with the rest of his army, where he was received with the greatest demonstrations of joy. Soon afterwards, Icetas, having grown weary of a private station, concluded a new peace with the Carthaginians, and, assembling an army, ventured an engagement with Timoleon; but in this he was utterly defeated, and Icetas himself, with Eupolemus his son, and Euthymus his general of horse, were brought bound to Timoleon by their own soldiers. The first two were immediately executed as tyrants and traitors, and the last murdered in cold blood; Icetas's wives and daughters were likewise cruelly put to death after a public trial. In a short time afterwards, Mamercus, another of the Carthaginian confederates, was overthrown by Timoleon, with the loss of 2000 men. These misfortunes induced the Carthaginians to conclude a peace on the conditions that all the Greek cities should be set free; that the river Halycus should be the boundary between the territories of both parties; that the natives of cities subject to the Carthaginians should be allowed to withdraw, if they pleased, to Syracuse or its dependencies, with their families and effects; and lastly, that Carthage should not, for the future, give any assistance to the remaining tyrants against Syracuse.

Peace concluded.

War renewed.

About 316 years before Christ, we find the Carthaginians engaged in another bloody war with the Sicilians. Sosistratus, who had usurped the supreme authority at Syracuse, having been forced by Agathocles to raise the siege of Rhegium, returned with his shattered troops to Sicily; but, soon after this unsuccessful expedition, he was obliged to abdicate the sovereignty and quit Syracuse. With him were expelled above 600 of the principal citizens, who were suspected of having formed a design to overturn the plan of government then established in the city. As Sosistratus and the exiles thought themselves ill treated, they had recourse to the Carthaginians, who readily espoused their cause. But the Syracusans, having recalled Agathocles, who had before been banished by Sosistratus, appointed him commander-in-chief of all their forces, principally on account of the known aversion he bore that tyrant. The war, however, did not then continue long; for Sosistratus and the exiles were quickly received again into the city, and peace was concluded with Carthage. The people of Syracuse, however, finding that Agathocles wanted to make himself absolute, exacted an oath from him that he would do nothing to the prejudice of the democracy. But notwithstanding this oath, Agathocles pursued his purpose, and, by a general massacre of the principal citizens of Syracuse, raised himself to the throne. For some time he was obliged to keep the peace he had concluded with Carthage; but at last, finding his authority established, and his subjects ready to second his ambitious designs, he paid no regard to treaties, and immediately made war on the neighbouring states, which he had expressly agreed not to do, after which he carried his arms into the very heart of the island. In these expeditions he was attended with such success, that in two years he brought into subjection all the Greek part of Sicily; and when this was accomplished, he committed great devastations in the Carthaginian territories, their general Hamilcar not offering to give him the least disturbance. Conduct so perfidious greatly incensed the people of those districts against Hamilcar, whom they accused before the senate. He died however, in Sicily, and Hamilcar the son of Gisco was appointed to succeed him in the command of the forces. The last place which held out against Agathocles was Messana, whither all the Syracusan exiles had retired. But Pasiphilus, Agathocles's general, found means to cajole the inhabitants into a treaty, which Agathocles, according to custom, paid no regard to; and as soon as he got possession of the town he cut off all those who had opposed his government; for, as he intended to prosecute the war with the utmost vigour against Carthage, he thought it a point of good policy to destroy as many of his Sicilian enemies as possible.

Agathocles raised to the throne of Syracuse.

In the mean time the Carthaginians having landed a powerful army in Sicily, an engagement soon ensued, in which Agathocles was defeated with the loss of 7000 men. After this defeat he was obliged to shut himself up in Syracuse, which the Carthaginians immediately invested, and most of the Greek states in the island submitted to them.

Agathocles, seeing himself stripped of almost all his dominions, and his capital itself in danger of falling into the hands of the enemy, formed a design, which, were it not attested by writers of undoubted authority, would seem absolutely incredible. This was no less than to transfer the war into Africa, and lay siege to the enemy's capital, at a time when he himself was besieged, and only one city left to him in all Sicily. Before he departed, however, he made all the necessary preparations for the defence of the place, and appointed his brother Antandrus governor. He also gave permission to all who were not willing to encounter the fatigues of a siege to retire out of the city. Many of the principal citizens accepted of this offer; but they had no sooner got out of the place than they were cut off by parties posted on the road for that purpose. Having seized upon their estates, Agathocles raised a considerable sum, which was intended in some measure to defray the expense of the expedition. He carried with him, however, only fifty talents to supply his present wants, being well assured that he should find in the enemy's country whatever was necessary for his subsistence. As the Carthaginians had a much superior fleet, they for some time kept the mouth of the harbour blocked up; but at last a fair opportunity offered, and Agathocles weighing anchor, soon got clear of both the port and city of Syracuse. The Carthaginians pursued him with all expedition; but notwithstanding their utmost efforts, Agathocles kept ahead, and landed his troops with very little opposition.

He invades Africa.

Soon after his forces had disembarked, Agathocles burnt his fleet, in order that his soldiers might behave with the greater resolution, when they saw all possibility of retreat cut off. He first advanced to a place called the Great City, which, after a feeble resistance, he took and plundered. He then marched to Tunis, which surrendered on the first summons; and Agathocles levelled both places with the ground.

He burns his fleet.

The Carthaginians were at first thrown into the greatest consternation. But, soon recovering themselves, the citizens took up arms with so much alacrity, that in a short time they raised an army of 40,000 foot and 1000 horse, with 2000 armed chariots, and intrusted the command to Hanno and Bomilcar, two generals between whom there subsisted a great animosity. But this disunion occasion-

Carthage. ed the defeat of their whole army, with the loss of their camp, although the force of Agathocles did not exceed 14,000 men. Among the rich spoils the conqueror found many chariots of curious workmanship, which carried 20,000 pairs of fetters and manacles which the enemy had provided for their expected prisoners. After this defeat, the Carthaginians, supposing themselves to have fallen under the displeasure of their deities on account of their neglecting to offer in sacrifice children of noble families, resolved to expiate this guilt. Accordingly two hundred children of the first rank were sacrificed to their gods, besides three hundred other persons who voluntarily offered themselves to pacify the wrath of these sanguinary deities.

Carthaginians defeated.

After these expiations Hamilcar was recalled from Sicily. When the messengers arrived, Hamilcar commanded them not once to mention the victory of Agathocles; but, on the contrary, to give out among the troops that he had been entirely defeated, his forces cut off, and his fleet destroyed by the Carthaginians. This threw the Syracusans into the utmost despair; however, one Eurymnon, an Etolian, prevailed upon Antandrus not to consent to a capitulation, but to stand a general assault. Hamilcar, informed of this, prepared his battering engines, and made all the necessary preparations for storming the town without delay. But while matters were in this situation, a galley, which Agathocles had caused to be built immediately after the battle, got into the harbour of Syracuse, and informed the inhabitants of the victory which he had obtained. Hamilcar, observing that the garrison flocked down to the port on this occasion, and expecting to find the walls unguarded, ordered his soldiers to erect scaling ladders, and begin the intended assault. The enemy having left the ramparts quite exposed, the Carthaginians mounted them without being discovered, and had almost possessed themselves of a portion situated between two towers, when the patrole discovered them. Upon this a warm contest ensued; and at last the Carthaginians were repulsed with loss. Hamilcar, therefore, finding it in vain to continue the siege after such glad tidings had revived the spirits of the Syracusans, drew off his forces, and sent a detachment of 5000 men to reinforce the troops in Africa. He still, however, entertained hopes that he might oblige Agathocles to quit Africa, and return to the defence of his own dominions. With this view he spent some time in making himself master of such cities as had sided with the Syracusans; and, after having brought all their allies under subjection, he returned again to Syracuse, hoping to surprise it in a night attack. But being attacked while advancing through narrow passes, where his numerous army had not room to act, he was defeated with great slaughter, taken prisoner, carried into Syracuse, and put to death.

Assault of Syracuse.

The siege raised.

In the mean time the Agrigentines, finding that the Carthaginians and Syracusans had greatly weakened each other by this war, thought it a proper opportunity for attempting to gain the sovereignty of the whole island. They therefore commenced a war against both parties; and prosecuted it with such success, that in a short time they wrested many places of consequence out of the hands both of the Syracusans and Carthaginians.

Success of Agathocles in Africa.

In Africa the tyrant carried every thing before him. He reduced most of the places of any importance in the territory of Carthage; and hearing that Elymas king of Libya had declared against him, he immediately entered Libya Superior, and in a great battle overthrew that prince, putting to the sword a considerable part of his troops, and the general who commanded them; after which he advanced against the Carthaginians with such expedition, that he surprised and defeated them with the loss of two thousand killed, and a great number taken prisoners. He next prepared for the siege of Carthage itself; and, with a view to this, advanced to a post within five miles of that city. On the other hand, notwithstanding the great losses they had already sustained, the Carthaginians encamped with a powerful army between him and their capital. In this situation Agathocles received advice of the defeat of the Carthaginian forces before Syracuse, and also the head of Hamilcar their general; upon which he immediately rode up to the enemy's camp, and showing them the head, gave them an account of the total destruction of their army before Syracuse. This threw them into such consternation, that in all human probability Agathocles would have made himself master of Carthage, had not an unexpected mutiny arisen in his camp, which gave the Carthaginians time to recover from their terror.

Carthage.

The year following an engagement happened, in which neither party gained any great advantage; but soon afterwards, the tyrant, notwithstanding all his victories, found himself unable to carry on the war alone; and he therefore endeavoured to gain over to his interest Ophellas, one of the captains of Alexander the Great. In this he succeeded perfectly; and in order to succour his new ally the more effectually, Ophellas sent to Athens for a body of troops. Having completed his military preparations, Ophellas found his army to consist of 10,000 foot and 600 horse, all regular troops, besides 100 chariots, and a body of 10,000 men, attended by their wives and children, as if he had been going to plant a new colony. At the head of these forces he continued his march towards the position of Agathocles for eighteen days, and then encamped at Automale, a city about three thousand stadia distant from the capital of his dominions. He then advanced through the *Regio Syrtica*, but found himself reduced to such extremities, that his army were in danger of perishing for want of bread, water, and other provisions. They were also greatly annoyed by serpents and wild beasts, with which that desert region abounded. The serpents made the greatest havock among the troops; for, being of the same colour with the earth, and extremely venomous, many soldiers, who trod upon without seeing them, were stung to death. At last, after a very fatiguing march of two months, he approached the position of Agathocles, and encamped at a small distance, to the no small terror of the Carthaginians, who apprehended the most fatal consequences from this junction. Agathocles at first caressed him, and advised him to take all possible care of his troops, who had undergone so many fatigues, but soon afterwards cut him off by treachery, and then by fair words and promises persuaded his troops to serve under himself.

His alliance with Ophellas.

Agathocles, now finding himself at the head of a numerous army, assumed the title of king of Africa, intending soon to complete his conquests by the reduction of Carthage. He began with the siege of Utica, which was taken by assault. He then marched against Hippo Diarrhytus, the Biserta of the moderns, which was also taken by storm; and after this most of the people bordering upon the sea-coasts, and even those who inhabited the inland parts of the country, submitted to him. But in the midst of this career of success, the Sicilians formed an association in favour of liberty, which obliged the tyrant to return home, leaving his son Archagathus to carry on the war in Africa.

Archagathus.

Archagathus, after his father's departure, greatly extended the African conquests. He sent Eumachus at the head of a large detachment to invade some of the neighbouring provinces, whilst he himself, with the greater part of his army, observed the motions of the Carthaginians. Eumachus passing into Numidia, first took the great city of Tocas, and conquered several of the Numidian cantons. Afterwards he besieged and took Phillina, which was at-

Carthage.

tended with the submission of the Asphodelodians, a nation, according to Diodorus, as black as the Ethiopians. He then reduced several cities; and being at last elated with his good fortune, resolved to penetrate into the most remote parts of Africa. And in this he at first met with success; but hearing that the barbarous nations were advancing in a formidable body to give him battle, he abandoned his conquests, and retreated with the utmost precipitation towards the sea-coast, after having lost a great number of men.

Reduced to the utmost distress.

This unfortunate expedition produced a great revolution in the affairs of Archagathus. The Carthaginians, informed of Eumachus's bad success, resolved to exert themselves in order to repair their former losses, and divided their forces into three bodies; one of these they sent to the sea-coast, to keep the towns there in awe; another they dispatched into the Mediterranean parts, to preserve the allegiance of the inhabitants there; and the last body they ordered to Upper Africa, in order to support their confederates in that country. Apprised of the motions of the Carthaginians, Archagathus likewise divided his forces into three bodies. One of these he sent to observe the Carthaginian troops on the sea-coast, with orders to advance afterwards into Upper Africa; another, under the command of Æschrion, one of his generals, he posted at a proper distance in the heart of the country, to observe both the enemy there and the barbarous nations; and with the last, which he led in person, he kept near Carthage, preserving a communication with the other two, in order to send them succours or recal them, as the exigency of affairs might require. The Carthaginian troops sent into the heart of the country were commanded by Hanno, a general of great experience, who, being informed of the approach of Æschrion, laid an ambuscade for him, into which he was drawn, and cut off with 4000 foot and 200 horse. Himilco, who commanded the Carthaginian forces in Upper Africa, having received advice of Eumachus's march, immediately advanced against him; and an engagement ensued, in which the Greeks were almost totally cut off, or perished with thirst after the battle; for out of 8000 foot only thirty, and of 800 horse only forty, had the good fortune to make their escape.

Archagathus having received the melancholy news of these two defeats, immediately called in the detachments he had sent out to harass the enemy, which would otherwise have been instantly cut off. He was, however, in a short time hemmed in on all sides, reduced to the last extremity for want of provisions, and ready every moment to be swallowed up by the numerous forces which surrounded him. In this deplorable situation Agathocles received an express from Archagathus, acquainting him of the losses which the latter had sustained, and the scarcity of provisions he laboured under. Upon this the tyrant, leaving the care of the Sicilian war to one Leptines, got out of the harbour, by a stratagem, eighteen Etruscan ships which came to his assistance; and then engaging the Carthaginian squadron which lay in its neighbourhood, took five of their ships, and made all their men prisoners. In this way he became master of the port, and secured a passage into it for the merchants of all nations, who soon restored plenty where the famine had before begun to make great havoc. Supplying himself, therefore, with a sufficient quantity of necessaries for the voyage which he was about to undertake, he immediately set sail for Africa.

Arrival of Agathocles in Africa.

Upon his arrival in that country, Agathocles reviewed his forces, and found them to consist of 6000 Greeks, and as many Samnites, Celtes, and Etruscans, besides 10,000 Africans and 1500 horse. As he found his troops in a state bordering on despair, he thought this a proper time for offering the enemy battle. The Carthaginians, however, did not think proper to accept the challenge, especially as, by keeping close in their camp, where they had plenty of every thing, they could starve the Greeks into a surrender without striking a blow. Upon this Agathocles attacked the Carthaginian camp with great bravery, made a considerable impression upon it, and might perhaps have carried it, had not his mercenaries deserted him almost at the first onset. By this piece of cowardice he was forced to retire with precipitation to his camp, whither the Carthaginians pursued him very closely, doing great execution in the pursuit.

Disaster in the Carthaginian camp.

The next night, the Carthaginians sacrificed all the prisoners of distinction, as a grateful acknowledgment to their gods for the victory they had gained. Whilst they were employed in this inhuman work, the wind, suddenly rising, carried the flames to the sacred tabernacle near the altar, which was entirely consumed, together with the general's tent, and those of the principal officers adjoining to it. A dreadful alarm was raised throughout the whole camp, which was heightened by the great progress of the fire; for as the soldiers' tents consisted of very combustible materials, and the wind blew in a most violent manner, the whole camp was almost entirely reduced to ashes; and many of the soldiers, endeavouring to carry off their arms and the rich baggage of their officers, perished in the flames. Some of those who made their escape met with a fate equally unhappy; for after the repulse of Agathocles the Africans deserted him, and were at that instant coming over in a body to the Carthaginians. But these the persons who were flying from the flames took to be the whole Syracusan army advancing in order of battle to attack their camp; upon which a dreadful confusion ensued, some taking to their heels, while others fell down in heaps one upon another, and many engaged their comrades, mistaking them for the enemy. Five thousand men lost their lives in this tumult, and the rest thought proper to take refuge within the walls of Carthage; nor could the appearance of daylight for some time dissipate their apprehensions. In the mean time the African deserters, observing the great confusion among the Carthaginians, and not knowing the meaning of it, were so terrified, that they thought proper to return to the place from which they had come. The Syracusans, seeing a body of troops advancing towards them in good order, concluded that the enemy were marching to attack them, and therefore immediately cried out, "To arms;" while the flames ascending from the Carthaginian camp into the air, and the lamentable outcries proceeding thence, confirmed them in this opinion, and greatly heightened their confusion. The consequence was much the same as in the Carthaginian camp; for coming to blows with one another instead of the enemy, they scarcely recovered their senses upon the return of light; and the intestine tumult proved so bloody that it cost Agathocles four thousand men.

Panic in that of Agathocles.

He escapes privately.

This last disaster so disheartened the tyrant, that he immediately set about contriving means for making his escape privately, which he at last effected, though with great difficulty. After his departure his two sons were immediately put to death by the soldiers, who, choosing a leader from among themselves, made peace with the Carthaginians upon the conditions that the Greeks should deliver up all the places which they held in Africa, on receiving from them three hundred talents; that such of them as were willing to serve in the Carthaginian army should be kindly treated, and receive the usual pay; and that the rest should be transported to Sicily, and have the city of Selinus allotted for their habitation.

Causes of the first Punic war.

From this time till the commencement of their first war with the Romans, we find nothing remarkable in the history

Carthage.

of the Carthaginians. The first Punic war, as it is commonly called, happened about 255 years before Christ. At that time the Carthaginians were possessed of extensive dominions in Africa; they had made considerable progress in Spain; they were masters of Sardinia, Corsica, and all the islands on the coast of Italy; and they had extended their conquests to a great part of Sicily. The occasion of the first rupture between the two republics may be briefly stated. The Mamertines, being vanquished in battle, and reduced to great straits, by Hiero, king of Syracuse, had resolved to deliver up Messina, the only city they now possessed, to that prince, with whose mild government and strict probity they were well acquainted. Accordingly, Hiero was advancing at the head of his troops in order to take possession of the city, when Hannibal, who at that time commanded the Carthaginian army in Sicily, prevented him by a stratagem. He came to meet Hiero as if to congratulate him on his victory, and amused him, whilst some of the Carthaginian troops filed off towards Messina. Meanwhile the Mamertines, seeing their city supported by a new reinforcement, were divided into several opinions. Some were for accepting the protection of Carthage, and others were for surrendering to the king of Syracuse; but the greater part declared for calling in the Romans to their assistance. Deputies were accordingly dispatched to Rome, offering the possession of the city to the Romans, and in the most moving terms imploring protection. This, after some debate, was agreed to; and the consul Appius Claudius received orders to attempt a passage to Sicily at the head of a powerful army. Being obliged to stay some time at Rome, however, one Caius Claudius, a person of great intrepidity and resolution, was dispatched with a few vessels to Rhegium. But, on his arrival there, he observed the Carthaginian squadron to be so much superior to his own, that he thought it hopeless to attempt at that time to transport forces to Sicily. He crossed the straits, however, and had a conference with the Mamertines, in which he prevailed with them to accept the proffered protection of Rome; and upon this he made the necessary preparations for transporting his forces. The Carthaginians, being informed of the resolution of the Romans, sent a strong squadron of galleys under the command of Hanno, to intercept the Roman fleet; and accordingly the Carthaginian admiral, coming up with them near the coast of Sicily, attacked them with great fury. During the engagement a violent storm arose, which dashed many of the Roman vessels against the rocks, and did a vast deal of damage to their squadron; in consequence of which Claudius was forced to retire to Rhegium, which he accomplished with great difficulty. Hanno restored all the vessels he had taken, but ordered the deputies sent with them to expostulate with the Roman general upon the infraction of the treaties subsisting between the two republics. This expostulation, however just, produced an open rupture; and Claudius soon afterwards took possession of Messina.

Hanno intercepts the Roman fleet.

Such was the beginning of the first Punic war, which lasted twenty-four years. The first year the Carthaginians and Syracusans laid siege to Messina, but, not acting in concert, as they ought to have done, were overthrown by the consul Appius Claudius; and this defeat so much disgusted Hiero with the Carthaginians, that he soon afterwards concluded an alliance with the Romans. After this treaty, having no enemy to contend with but the Carthaginians, the Romans made themselves masters of all the cities on the western coast of Sicily, and at the end of the campaign withdrew most of their troops to winter quarters in Italy.

Carthaginians and Syracusans defeated.

The second year, Hanno the Carthaginian general fixed his principal magazine at Agrigentum. Strong by nature, this place had been rendered almost impregnable by the new fortification which the Carthaginians had raised during the preceding winter, and was defended by a numerous garrison, commanded by Hannibal, a general of great experience in war. For five months the Romans attempted to reduce the place by famine, and had actually brought the inhabitants to great distress, when a Carthaginian army of 50,000 foot, 6000 horse, and sixty elephants, landed at Lilybæum, and marched thence to Heraclea, within twenty miles of Agrigentum. There the general received a deputation from some of the inhabitants of Erbessa, where the Romans had their magazines, offering to put the town into his hands. It was accordingly delivered up; and by this means the Romans became so much distressed, that they would certainly have been obliged to abandon their enterprise, had not Hiero supplied them with provisions. All the assistance he was able to give, however, would not long have supported them, as their army was so much weakened by famine, that out of 100,000 men, of whom it originally consisted, scarcely a fourth part remained fit for service, and could no longer subsist on such inadequate supplies as were furnished them. But in the mean time Hannibal acquainted Hanno that the city was reduced to the utmost distress; upon which he resolved to venture an engagement, which he had previously declined. In this, however, the Romans were victorious, and the city surrendered at discretion, though Hannibal and the greater part of the garrison made their escape. This ended the campaign; and the Carthaginians being greatly chagrined at their bad success, fined Hanno in an immense sum of money, and deprived him of his command, appointing Hamilcar to succeed him in the command of the army, and Hannibal in that of the fleet.

Carthage.

The third year, Hannibal received orders to ravage the coast of Italy; but the Romans had taken care to post detachments in such places as were judged most proper to prevent his landing, so that the Carthaginian found it impossible to execute his orders. At the same time, the Romans, perceiving the advantages of being masters of the sea, set about building a hundred and twenty galleys. While this work was in progress they made themselves masters of most of the inland cities, but the Carthaginians reduced or kept steady in their interest most of the maritime ones; so that both parties were equally successful during this campaign.

The fourth year Hannibal by a stratagem made himself master of seventeen Roman galleys; after which he committed great ravages on the coast of Italy, whither he had advanced to take a view of the Roman fleet. But he was afterwards attacked in his turn, lost the greater part of his ships, and with great difficulty made his own escape; and soon afterwards he was totally defeated by the consul Duilius, with the loss of eighty ships taken, thirteen sunk, 7000 men killed, and as many taken prisoners. After this victory Duilius landed in Sicily, put himself at the head of the land forces, relieved Segesta, which was besieged by Hamilcar, and made himself master of Macella, though defended by a numerous garrison.

The Carthaginians defeated at sea.

The fifth year a difference arose between the Romans and their Sicilian allies, which proceeded to such a height that they encamped separately. Of this Hamilcar availed himself, and attacking the Sicilians in their entrenchments, put 4000 of them to the sword. He then drove the Romans from their posts, took several cities, and overran the greater part of the country. In the mean time Hannibal, after his defeat, sailed with the shattered remains of his fleet to Carthage. But, in order to secure himself from punishment, he sent one of his friends with all speed, before the event of the battle was known there, to acquaint the senate that the Romans had put to sea

Sicilians defeated.

Carthage.

with a great number of heavy ill-built vessels, each of them carrying some machine, the use of which the Carthaginians did not understand; and he asked whether it was the opinion of the senate that Hannibal should attack them. These machines were the *corvi*, then newly invented, and by means of which, chiefly, Duilius had gained the victory. The senate were unanimous in their opinion that the Romans should be attacked; upon which the messenger acquainted them with the unfortunate event of the battles. As the senators had already declared themselves for the engagement, they spared their general's life, and, according to Polybius, even continued him in the command of the fleet. Accordingly, being reinforced by a good number of galleys, and attended by some officers of great merit, he in a short time sailed for the coast of Sardinia. But he had not been long there before he was surprised by the Romans, who carried off many of his ships, and took great numbers of his men prisoners; which so incensed the rest, that they seized their unfortunate admiral, and crucified him. It does not appear who was his immediate successor.

Corsica and Sardinia reduced.

The sixth year the Romans made themselves masters of the islands of Corsica and Sardinia. Hanno, who commanded the Carthaginian forces in the latter, defended himself at a city called Olbia with incredible bravery; but being at last killed in one of the attacks, the place was surrendered, and the Romans soon became masters of the whole island.

The Roman army rescued from great danger by a legionary tribune.

The seventh year the Romans took the town of Mytestratum, in Sicily, whence they marched towards Camarina; but in their way they were surrounded in a deep valley, and in the most imminent danger of being cut off by the Carthaginian army. In this extremity a legionary tribune, called M. Calpurnius Flamma, desired the general to give him three hundred chosen men, promising, with this small company, to find the enemy such employment as should oblige them to leave a passage open for the Roman army. He performed his promise with a bravery truly heroic; for having seized an eminence in spite of all opposition, and intrenched himself on it, the Carthaginians, jealous of his design, flocked from all quarters to drive him from his post. But the brave tribune kept their whole army in play, till the consul, taking advantage of the diversion, drew his army out of the perilous situation into which he had imprudently brought it. The legions were no sooner out of danger than they hastened to the relief of their brave companions; but all they could do was to save their bodies from the insults of their enemies; for they found them all dead on the spot except Calpurnius, who lay under a heap of dead bodies covered with wounds, but still breathing. His wounds were immediately dressed, and it fortunately happened that none of them proved mortal; and for this glorious enterprise he received a crown of *gramen*. After this the Romans reduced several cities, and drove the enemy out of the territory of the Agrigentines; but they were in turn repulsed with great loss before Lipara.

Regulus.

The eighth year Regulus, who commanded the Roman fleet, observing that of the Carthaginians lying along the coast in disorder, sailed with a squadron of ten galleys, to reconnoitre their number and strength, ordering the rest of the fleet to follow him with all expedition. As he drew too near the enemy, however, he was surrounded by a great number of Carthaginian galleys. The Romans fought with their usual bravery; but being overpowered with numbers, they were obliged to yield. The consul, however, found means to make his escape, and join the rest of the fleet; and then he had his full revenge of the enemy, eighteen of their ships being taken, and eight sunk.

He invades Africa.

The ninth year the Romans made preparations for invading Africa. The fleet prepared for this purpose consisted of 330 galleys, each of them having on board 120 soldiers and 300 rowers. The Carthaginian fleet consisted of 360 sail, and was much better manned than that of the Romans. The two fleets met near Ecnomus, a promontory of Sicily; where, after a bloody engagement, which lasted the greater part of the day, the Carthaginians were entirely defeated, with the loss of thirty galleys sunk and sixty-three taken. The Romans lost only twenty-four galleys, which were all sunk. After this victory, the Romans having refitted their fleet, set sail for the coast of Africa with all expedition, and arrived before Clupea, a city to the east of Carthage, where they made their first descent. No words can express the consternation of the Carthaginians on the arrival of the Romans in Africa. The inhabitants of Clupea were so terrified, that they abandoned the place, which the Romans immediately took possession of, and having left there a strong garrison to secure their shipping, and keep the adjacent territory in awe, moved nearer Carthage, taking a great number of towns in their advance. They likewise plundered a prodigious number of villages, laid many noblemen's seats in ashes, and took above 20,000 prisoners. In short, having plundered and ravaged the whole country, almost to the gates of Carthage, they returned to Clupea loaded with an immense booty which they had acquired in the expedition.

Success of Regulus.

The tenth year Regulus pushed on his conquests with great rapidity. To oppose his progress, Hamilcar was recalled from Sicily, and with him Bostar and Asdrubal were joined in command. Hamilcar commanded an army about equal to that of Regulus. The other two commanded separate bodies, which were to join him or act separately as occasion required. But before they were in a condition to take the field, Regulus, pursuing his conquests, arrived on the banks of the Bagrada, a river which empties itself into the sea at a small distance from Carthage. Having passed this river, he besieged Adis, or Adda, not far from Carthage, which the enemy attempted to relieve; but as they lay encamped among hills and rocks, where their elephants, in which the main strength of their army consisted, could be of no use, Regulus attacked them in their lines, killed 17,000, and took 5000 prisoners and eighteen elephants. On receiving the tidings of this victory, deputations came from all quarters, insomuch that the conqueror in a few days became master of eighty towns, among which were the city and port of Utica. This increased the alarm at Carthage, which was reduced to despair when Regulus laid siege to Tunis, a great city about nine miles distant from the capital. The place was taken in sight of the Carthaginians, who, from their walls, beheld all the operations of the siege, without making the least attempt to raise it. And, to complete their misfortunes, the Numidians, their neighbours and implacable enemies, entered their territories, committing everywhere the most dreadful devastations. In this extremity Regulus advanced to the very gates of Carthage; and, having encamped under the walls, sent deputies to treat of a peace with the senate. The deputies were received with inexpressible joy; but the conditions which they proposed were such that the senate could not listen to them without the greatest indignation. They were, that the Carthaginians should relinquish all claims to Sardinia, Corsica, and Sicily; that they should restore to the Romans all the prisoners they had taken since the beginning of the war; that if they wished to redeem any of their own prisoners, they should pay as much a head for them as Rome should judge reasonable; that they should for ever pay the Romans an annual tribute; and that for the future they should fit out but one man of war for their own use, and fifty triremes to serve in the

The Carthaginians defeated.

His proposals of peace rejected.

Carthage. Roman fleet, at the expense of Carthage, when required by any of the future consuls. These extravagant demands provoked the senators, who loudly and unanimously rejected them; the Roman deputies, however, told them that Regulus would not alter a single letter of the proposals, and that they must either conquer the Romans or accept them.

Xanthippus appointed to command.

In this desperate emergency some mercenaries arrived from Greece, among whom was a Lacedemonian, by name Xanthippus, a man of approved valour and experience in war. This man having informed himself of the circumstances of the late battle, declared publicly that their overthrow was more owing to their own misconduct than to the superiority of the enemy. This discourse having spread abroad, came at last to the knowledge of the senate, by whom, with the concurrence even of the Carthaginian generals themselves, Xanthippus was appointed commander-in-chief of their forces. The first care of this officer was to discipline his troops in a proper manner. He taught them how to march, encamp, widen and close their ranks, and rally after the Lacedemonian manner under their proper colours. He then took the field with 12,000 foot, 4000 horse, and 100 elephants. The Romans were surprised at the sudden alteration which they observed in the enemy's conduct; but Regulus, elated with his former success, came and encamped at a small distance from the Carthaginian army, in a vast plain, where their elephants and horse had room to act. The two armies were separated by a river, which Regulus boldly passed, thus leaving no room for a retreat in case of any misfortune. The engagement began with great fury, but ended in the total defeat of the Romans, who, with the exception of 2000 who escaped to Clupea, were all killed or taken prisoners; and among the latter was Regulus himself. The loss of the Carthaginians scarcely exceeded 800 men. The Carthaginians remained on the field of battle till they had stripped the slain; and then entered their metropolis, which was almost the only place left them, in great triumph. They treated all their prisoners with great humanity, except Regulus; but as for him, he had so insulted them in his prosperity, that they could not forbear showing him the highest marks of their resentment. According to Zonaras and others, he was thrown into a dungeon, where he had only sustenance allowed him sufficient to keep him alive; while his cruel masters, in order to heighten his other torments, directed a huge elephant, at the sight of which animal he was it seems greatly terrified, to be constantly placed near him, and thus prevented him from enjoying any tranquillity or repose.

The Romans defeated, and Regulus taken.

Carthaginians defeated by sea and land.

In the eleventh year of this war, the Carthaginians, elated with their victory over Regulus, began to talk in a very high strain, threatening Italy itself with an invasion. To prevent this, the Romans took care to garrison all their maritime towns, and fitted out a new fleet. In the mean time, the Carthaginians besieged Clupea and Utica in vain, being obliged to abandon their enterprise upon hearing that the Romans were equipping a fleet of 350 sail. The Carthaginians having with incredible expedition refitted their old vessels, and built a considerable number of new ones, met the Roman fleet off Cape Hermea. An engagement ensued, in which the Carthaginians were utterly defeated; 104 of their ships being sunk, thirty taken, and 15,000 of their soldiers and rowers killed in the action. The Romans pursued their course to Clupea, where they had no sooner landed than they found themselves attacked by the Carthaginian army under the two Hannos, father and son. But the brave Xanthippus no longer commanded their army; and, notwithstanding the Lacedemonian discipline he had introduced among them, they were routed at the very first onset, with the loss of 9000 men, among whom were many of their chief lords.

Notwithstanding all their victories, however, the Romans found themselves obliged, for want of provisions, to evacuate both Clupea and Utica, and abandon Africa. But being desirous of signalizing the end of their consulate by some important conquest in Sicily, the consuls steered for that island, contrary to the advice of their pilots, who represented the danger they incurred on account of the season being far advanced. Their obstinacy, however, led to the destruction of the whole fleet; for a violent storm arising, out of 370 vessels only eighty escaped shipwreck, the rest being swallowed up by the sea, or dashed in pieces against the rocks. This was by far the greatest loss that Rome had ever sustained; for besides the ships which were cast away with their crews, a numerous army was destroyed, with all the riches of Africa, which had been amassed by Regulus and deposited in Clupea, and were now being transported thence to Rome. The whole coast from Pachinum to Camerina was covered with dead bodies and wrecks of ships; so that history scarcely affords an example of a more dreadful disaster.

Carthage

Romans abandon Africa.

Their fleet destroyed in a storm.

The twelfth year the Carthaginians, hearing of this misfortune of the Romans, renewed the war in Sicily with fresh fury, hoping the whole island, which was now left defenceless, would fall into their hands. Carthalo, a Carthaginian commander, besieged and took Agrigentum. He laid the town in ashes, and demolished the walls, obliging the inhabitants to fly to Olympium. Upon the news of this success, Asdrubal was sent to Sicily with a large reinforcement of troops and 150 elephants. They likewise fitted out a squadron, with which they retook the island of Corcyra, and marched a strong body of forces into Mauritania and Numidia, to punish the people of those countries for showing a disposition to join the Romans. In Sicily the Romans possessed themselves of Cephalodium and Panormus, but were obliged by Carthalo to raise the siege of Drepanum with great loss.

A new fleet fitted out, and also destroyed.

The thirteenth year the Romans sent out a fleet of 260 galleys, which appeared off Lilybæum in Sicily; but finding this place too strong, they steered from thence to the eastern coast of Africa, where they effected several descents, surprised some cities, and plundered several towns and villages. They arrived safely at Panormus, and in a few days set sail for Italy, having a fair wind till they came off Cape Palinurus, where a violent storm overtook them, and 160 of their galleys, with a great number of their transports, were lost; upon which the Roman senate decreed, that in future not more than fifty vessels should be equipped, and that these should be employed only in guarding the coast of Italy, and in transporting troops into Sicily.

The fourteenth year the Romans made themselves masters of Himera and Lipara in Sicily; and the Carthaginians conceiving new hopes of conquering that island, began to make fresh levies in Gaul and Spain, and to equip a new fleet. Their treasures were exhausted, and they applied to Ptolemy, king of Egypt, intreating him to lend them two thousand talents; but he, being resolved to remain neutral, refused to comply with their request, telling them that he could not, without a breach of fidelity, assist one friend against another. However, the republic of Carthage, by a great effort, equipped a fleet of 200 sail, raised an army of 30,000 men, with 140 elephants, and appointed Asdrubal commander-in-chief both of the fleet and army. Meanwhile the Romans, finding the great advantage of a fleet, resolved to equip one, notwithstanding all former disasters; and whilst the vessels were building, two consuls, men of valour and experience, were chosen to supersede those acting in Sicily. But Metellus, one of the former consuls, being continued with the title of proconsul, found means to draw Asdrubal into a battle on dis-

Carthage.

Carthaginians defeated.

advantageous terms near Panormus, and then sallying out, overthrew him with a terrible slaughter. Twenty thousand of the enemy were killed, and many elephants destroyed. A hundred and four elephants, with their leaders, were taken, and sent to Rome, where they were hunted and put to death in the circus.

The fifteenth year the Romans besieged Lilybæum, and the siege continued during the rest of the first Punic war, being the only thing remarkable that happened during that time. The Carthaginians, on the first news of its being besieged, sent Regulus with some deputies to Rome to treat for a peace; but instead of forwarding the negotiation, Regulus hindered it; and notwithstanding he knew the torments prepared for him at Carthage, could not be prevailed upon to stay at Rome, but returning to captivity, was put to death in a most cruel manner. During this siege, the Roman fleet under Claudius Pulcher was utterly defeated by Adherbal the Carthaginian admiral. Ninety of the Roman galleys were lost in the action, 8000 men were either killed or drowned, and 20,000 taken and sent prisoners to Carthage; while the Carthaginians gained this signal victory without the loss of a single ship, or even a single man. Another Roman fleet met with a still harder fate. It consisted of 120 galleys and 800 transports, and was laden with all sorts of military stores and provisions. Every one of these vessels was lost in a storm, with all they contained, not a single plank being saved that could be used again; so that the Romans found themselves once more deprived of their whole naval force.

Hamilcar Barcas sent into Sicily.

In the mean time the Carthaginian soldiery having shown a disposition to mutiny, the senate sent Hamilcar Barcas, father of the celebrated Hannibal, into Sicily. He received *carte blanche* from the senate to act as he thought proper; and by his excellent conduct and resolution, he showed himself the greatest general of his age. Eryx, which he had taken by surprise, he defended with such vigour that the Romans would never have been able to make themselves masters of it, had they not fitted out, at the expense of private citizens, a fleet which utterly defeated that of the Carthaginians; so that Hamilcar, notwithstanding all his valour, was obliged to yield up the place which he had long and bravely defended. Articles of peace were immediately agreed to between the two commanders. The Carthaginians were to evacuate all the places which they occupied in Sicily, and entirely quit that island; to pay the Romans in twenty years, and by equal payments every year, 2200 talents of silver, or about L.437,250 sterling; to restore the Roman captives and deserters without ransom, and redeem their own prisoners with money; and to refrain from making war upon Hiero king of Syracuse or his allies. These articles being agreed to, Hamilcar surrendered Eryx upon condition that all his soldiers should march out with him, on his paying for each of them eighteen Roman *denarii*. Hostages were mutually given, and deputies sent to Rome to procure a ratification of the treaty by the senate. When the senators had thoroughly informed themselves as to the state of affairs, two more articles were added, namely, that 1000 talents should be paid immediately, and the 2200 in the space of ten years in equal payments; and that the Carthaginians should quit all the little islands about Italy and Sicily, and never more approach them with ships of war, or raise mercenaries in those places. Necessity obliged Hamilcar to consent to these terms; but he returned to Carthage with a hatred of the Romans, which he did not even suffer to die with him, but transmitted to his son the illustrious Hannibal.

Peace.

War with the Mercenaries.

The Carthaginians were no sooner freed from this sanguinary and expensive war than they found themselves engaged in another of the most dangerous kind. It is called by ancient historians the Libyan War, or the War with the Mercenaries. The principal cause of this war may be shortly stated. When Hamilcar returned to Carthage, he found the republic so much impoverished, that, far from being able to give these troops the largesses and rewards promised them, it could not pay them their arrears. He had committed the care of transporting them to one Gisco, an officer of great penetration, who, as if he had foreseen what would happen, did not ship them off all at once, but in small and separate parties, in order that those who landed first might be paid off and sent home before the arrival of the rest. The Carthaginians, however, did not act with the same prudence as Gisco. As the state was almost entirely exhausted by the late war, and the immense sum of money paid to the Romans in consequence of the peace, they judged it proper to endeavour to save something to the public, and with this view they did not pay off the mercenaries as they arrived, thinking it better to wait till they had all arrived, in the hope of obtaining some remission of their arrears. But, being soon made sensible of their error, by the frequent disorders of which these barbarians were guilty in the city, they with some difficulty prevailed on the officers to take up their quarters at Sicca, and canton their troops in that neighbourhood. To induce them to do so, however, they gave them a sum of money for their present subsistence, and promised to comply with their demands when the remainder of the troops should have arrived from Sicily. But the troops, being wholly immersed in idleness, to which they had long been strangers, a neglect of discipline ensued, and of course a petulant and licentious spirit immediately showed itself. They were now determined not to acquiesce in receiving their bare pay, but to insist upon the rewards which Hamilcar had promised them, and even to compel the state of Carthage by force of arms to comply with their demands. The senate being informed of the mutinous disposition of the soldiery, dispatched Hanno, one of the suffetes, to pacify them. Upon his arrival at Sicca, he expatiated largely on the poverty of the state, and the heavy taxes with which the citizens of Carthage were loaded; and, instead of answering their extravagant expectations, he desired them to be satisfied with receiving part of their pay, and to remit the remainder in consideration of the pressing exigencies of the republic. But the mercenaries, highly provoked that neither Hamilcar nor any other of the principal officers who commanded them in Sicily, and were the best judges of their merit, made their appearance on this occasion, but only Hanno, a person utterly unknown, and above all others disagreeable to them, immediately had recourse to arms; and assembling in a body, to the number of 20,000, they advanced to Tunis, and immediately encamped before that city.

The Carthaginians, being greatly alarmed at the approach of so formidable a body to Tunis, made large concessions to the mercenaries, in order to bring them back to their duty; but, far from being softened, the latter grew more insolent upon these concessions, considering them as the effects of fear, and therefore became altogether averse to thoughts of accommodation. Making a virtue of necessity, the Carthaginians showed a disposition to satisfy them in all points, and agreed to refer the points at issue to the opinion of some general in Sicily, as they had all along desired, leaving the choice of such commander entirely to the soldiery themselves. Gisco was accordingly pitched upon to mediate this affair, the mercenaries believing Hamilcar to have been a principal cause of the ill treatment they had met with, since he never appeared amongst them, and, according to the general opinion, had voluntarily resigned his commission. Gisco soon arrived at Tunis with money to pay the troops; and, after confer-

ring with the officers of the several nations apart, he harangued them in such a manner, that a treaty was upon the point of being concluded, when Spendius and Mathos, two of the principal mutineers, occasioned a tumult in every part of the camp. Spendius was by nation a Campanian, and had been a slave at Rome, whence he fled to the Carthaginians. The apprehensions he entertained of being delivered up to his old master, by whom he was sure to be hanged or crucified, prompted him to break off the accommodation. Mathos was an African, and free born; but as he had been active in raising the rebellion, and was well acquainted with the implacable disposition of the Carthaginians, he knew that a peace must infallibly prove his ruin. He therefore joined with Spendius, and insinuated to the Africans the danger of concluding at that juncture a treaty, which could not but leave them exposed singly to the rage of the Carthaginians. This so incensed the Africans, who were much more numerous than the troops of any other nation, that they immediately assembled in a tumultuous manner, and the foreigners soon joined them, being inspired by Spendius with an equal degree of fury. Nothing was now to be heard but the most horrid oaths and imprecations against Gisco and the Carthaginians. Whoever offered to make any remonstrance, or lend an ear to temperate counsels, was stoned to death by the enraged multitude; and many persons lost their lives for attempting to speak, before it could be known whether they were in the interest of Spendius or of the Carthaginians.

In the midst of these commotions Gisco behaved with great firmness and intrepidity, and left no methods untried to soften the officers and calm the minds of the soldiery; but the torrent of sedition was now so strong, that there was no possibility of keeping it within bounds. They therefore seized upon the military chest, dividing the money among themselves as part payment of their arrears; put the person of Gisco under an arrest; and treated him, as well as his attendants, with the utmost indignity. Mathos and Spendius, in order to destroy all hopes of an accommodation with Carthage, applauded the courage and resolution of their men, loaded the unhappy Gisco and his followers with irons, and formally declared war against the Carthaginians. The cities of Africa to which deputies had been sent to exhort them to recover their liberty soon came over to them, except Utica and Hippo Diarrhytus. And the army being thus greatly increased, they divided it into two parts, with one of which they moved towards Utica, whilst the other marched to Hippo, in order that both places might be simultaneously besieged. The Carthaginians, in the mean time, found themselves ready to sink under the pressure of their misfortunes. After they had been harassed twenty-four years by a most cruel and destructive foreign war, they entertained some hopes of enjoying repose. The citizens of Carthage drew their individual subsistence from the rents or revenues of their lands, and the public expenses from the tribute paid by Africa; all which they were not only deprived of at once, but, what was worse, had it directly turned against them. They were destitute of arms and forces either by sea or land, and had made no preparations for sustaining a siege, or the equipping of a fleet. They suffered all the calamities incident to the most ruinous civil war; and, to complete their misery, had not the least prospect of receiving assistance from any foreign friend or ally. Notwithstanding their deplorable situation, however, they did not despair, but pursued all the measures necessary to put themselves in a suitable posture of defence.

Hanno was dispatched to the relief of Utica with a considerable body of forces, 100 elephants, and a large train of battering engines. Having reconnoitred the enemy, he immediately attacked their intrenchments, and, after an obstinate contest, forced them. The mercenaries lost a vast number of men, and consequently the advantages gained by Hanno were so great, that they might have proved decisive had he made a proper use of them; but victory having rendered him too confident, and his troops neglecting their duty, the mercenaries rallied their forces, fell upon him, cut off many of his men, forced the rest to fly into the town, retook and plundered the camp, and seized all the provisions and military stores brought to the relief of the besieged. Nor was this the only instance of Hanno's military incapacity. Notwithstanding he lay encamped in the most advantageous manner, near a town called Gorza, where he twice overthrew the enemy, and had it in his power to ruin them totally, he yet neglected to improve these advantages, and even suffered the mercenaries to possess themselves of the isthmus which joined to the continent of Africa the peninsula on which Carthage stood.

These repeated mistakes induced the Carthaginians once more to place Hamilcar Barcas at the head of their forces. This commander marched against the enemy with 10,000 men, horse and foot, being all the troops the Carthaginians could then assemble for their defence; a proof of the very low state to which they had at that time been reduced. As Mathos, after the occupation of the isthmus, had posted proper detachments in the passes of two hills facing the continent, and guarded the bridge over the Bagrada, which through Hanno's neglect he had taken, Hamilcar saw little probability of engaging him upon equal terms, or indeed of even getting at him. Observing, however, that on the blowing of certain winds the mouth of the river was choked up with sand, so as to become passable, though with no small difficulty, while these winds continued, he halted at the river's mouth, without communicating his design to any person. As soon as the wind favoured his project, he crossed the river privately by night, and immediately after his passage drew up the troops in order of battle; and advancing into the plain, where his elephants were capable of acting, moved towards Mathos, who was posted at the village near the bridge. This daring action greatly surprised and intimidated the Africans. However, Spendius, receiving intelligence of the enemy's motions, drew a body of 10,000 men out of Mathos's camp, with which he attended Hamilcar on one side, and ordered 15,000 from Utica to observe him on the other; thinking by this means to surround the Carthaginians, and cut them off at one stroke. But by feigning a retreat, Hamilcar found means to engage them at a disadvantage, and gave them a total overthrow, with the loss of 6000 killed and 2000 taken prisoners, while the rest fled, some to the town at the bridge, and others to the camp at Utica. He did not give them time to recover from their defeat, but pursued them to the town near the bridge before mentioned, which he entered without opposition, the mercenaries flying in great confusion to Tunis; and upon this many towns submitted of their own accord to the Carthaginians, whilst others were reduced to subjection by force of arms.

Notwithstanding these disasters, Mathos pushed on the siege of Hippo with great vigour, and appointed Spendius and Autaritus, commanders of the Gauls, with a strong body, to observe the motions of Hamilcar. These commanders, therefore, at the head of a choice detachment of 6000 men drawn out of the camp at Tunis, and 2000 Gallic horse, attended the Carthaginian general, approaching him as near as they could with safety, and keeping close to the skirts of the mountains. At last Spendius having received a strong reinforcement of Africans and Numidians, and occupied all the heights surrounding the plain in which Hamilcar lay encamped, resolved not to let

Carthage.

slip so favourable an opportunity of attacking him. Had a battle now ensued, Hamilcar and his army must in all probability have been cut off; but, by the desertion of one Naravasus, a young Numidian nobleman, with 2000 men, he found himself enabled to offer his enemies battle. The fight was obstinate and bloody; but at last the mercenaries were entirely overthrown, with the loss of 10,000 men killed and 4000 taken prisoners. All the prisoners who were willing to enlist in the Carthaginian service Hamilcar received into his army, supplying them with the arms of the soldiers who had fallen in the engagement; and to the rest he gave full liberty to go where they pleased, upon condition that they should never for the future bear arms against the Carthaginians; informing them, at the same time, that every violator of this agreement who fell into his hands must expect no mercy.

Mathos and his associates, fearing that this affected lenity of Hamilcar might occasion a defection among the troops, thought that the best expedient would be to put them upon some action so execrable in its own nature that no hopes of reconciliation should remain. By their advice, therefore, Gisco, and all the Carthaginian prisoners were put to death; and when Hamilcar sent to demand the remains of his countrymen, he received for answer, that whoever presumed hereafter to come upon that errand, should meet with Gisco's fate; after which they came to a resolution to treat with the same barbarity all Carthaginians who should fall into their hands. In return for this enormity, Hamilcar delivered up all the prisoners who fell into his hands to be devoured by wild beasts; being convinced that compassion served only to render his enemies more fierce and untractable.

The war was now carried on generally to the advantage of the Carthaginians; nevertheless, the malcontents still found themselves in a capacity to take the field with an army of 50,000 men. They watched Hamilcar's motions, but kept on the hills, carefully avoiding to come down into the plains, on account of the Numidian horse and Carthaginian elephants. But Hamilcar, being much superior in skill to any of their generals, at last shut them up in a post so situated that it was impossible to get out of it. Here he kept them strictly besieged; and the mercenaries, not daring to venture a battle, began to fortify their camp, and surround it with ditches and intrenchments. But they were soon pressed so sorely by famine, that they were obliged to eat one another; yet as they were rendered desperate by the consciousness of their guilt, they did not desire any terms of accommodation. At last, being reduced to the utmost extremity of misery, they insisted that Spendius, Autaritus, and Zarxas, their leaders, should in person have a conference with Hamilcar, and make proposals to him. Peace was accordingly concluded, upon the conditions that ten of the ringleaders of the malcontents should be left entirely to the mercy of the Carthaginians, and that the troops should all be disarmed, every man retiring only in a single coat. The treaty was no sooner concluded than Hamilcar, by virtue of the first article, seized upon the negotiators themselves; and the army being informed that their chiefs were under arrest, had immediately recourse to arms, suspecting they were betrayed; but Hamilcar, drawing out his army in order of battle, surrounded them, and either cut them to pieces or trod them to death with his elephants. The number of wretches who perished on this occasion amounted to above 40,000.

Terrible defeat of the mercenaries.

After the destruction of the army, Hamilcar invested Tunis, whither Mathos had retired with his remaining forces. The former had another general, named Hannibal, joined in the command with him. Hannibal's quarters were on the road leading to Carthage, and Hamilcar's on the opposite side. The army was no sooner encamped, than Hamilcar caused Spendius and the rest of the prisoners to be led out in the view of the besieged, and crucified near the walls. Mathos, however, observing that Hannibal did not keep so good a guard as he ought to have done, made a sally, attacked his quarters, killed many of his men, made several prisoners, among whom was Hannibal himself, and plundered his camp. Taking down the body of Spendius from the cross, Mathos immediately substituted Hannibal in its stead; and thirty Carthaginian prisoners of distinction were crucified around him. After this disaster, Hamilcar decamped, and posted himself along the sea-coast, near the mouth of the river Bagrada.

The senate, though greatly terrified by so unexpected a blow, omitted no means necessary for their preservation. They sent thirty senators, with Hanno at their head, to consult with Hamilcar about the proper measures for putting an end to this unnatural war; conjuring Hanno in the most pressing manner to be reconciled to Hamilcar, and to sacrifice his private resentment to the public benefit. This was effected with some difficulty; and the two generals came to a full resolution to act in concert for the good of the public. The senate, at the same time, ordered all the youth capable of bearing arms to be pressed into the service; and by these means a strong reinforcement being sent to Hamilcar, he soon found himself in a condition to act offensively. He now defeated the enemy in every rencounter, drew Mathos into frequent ambuscades, and gave him one notable overthrow near Leptis. This reduced the rebels to the necessity of hazarding a decisive battle, which proved fatal to them. The mercenaries fled almost at the first onset, and most of their army fell either in the field of battle or in the pursuit. Mathos, with a few, escaped to a neighbouring town, where he was taken alive, carried to Carthage, and executed; and then, by the reduction of the revolted cities, an end was put to this war, which, from the excesses of cruelty committed in it, went among the Greeks by the name of the *inexpiable war*.

During the Libyan war, the Romans, upon some absurd pretences, wrested from the Carthaginians the island of Sardinia; and the latter, not being able to resist, were obliged to submit to the loss. Hamilcar, finding his country not in a condition to enter into an immediate war with Rome, formed a scheme to put it on a level with that haughty republic. This was by making an entire conquest of Spain, by which means the Carthaginians might have troops capable of contending with the Romans. In order to facilitate the execution of this scheme, he inspired both his son-in-law Asdrubal, and his son Hannibal, with an implacable aversion to the Romans, as the great enemies of his country's grandeur. And having completed all the necessary preparations, Hamilcar, after greatly enlarging the Carthaginian dominions in Africa, entered Spain, where he commanded nine years, during which time he subdued many warlike nations, and amassed an immense quantity of treasure, which he distributed partly amongst his troops and partly amongst the great men at Carthage, by which means he supported his interests with these two powerful bodies. At last he was killed in a battle, and was succeeded by his son-in-law Asdrubal. This general fully answered the expectations of his countrymen, having greatly enlarged their dominions in Spain, and built the city of New Carthage, now Carthagena. He made such progress in his conquests that the Romans began to be alarmed. They did not, however, choose at present to come to an open rupture, on account of the apprehensions which they entertained of an invasion by the Gauls. They judged it most proper, therefore, to have recourse to milder methods; and prevailed upon Asdrubal to conclude a new treaty with them, upon the conditions

Hamilcar's scheme to equal Carthage with Rome.

Asdrubal.

Carthage. that the Carthaginians should not pass the Iberus; and that the Saguntines, a colony of Zacynthians, and a city situated between the Iberus and that part of Spain subject to the Carthaginians, as well as the other Greek colonies there, should enjoy their ancient rights and privileges.

Murder of Asdrubal. Asdrubal, after having governed the Carthaginian dominions in Spain for eight years, was treacherously murdered by a Gaul, whose master he had put to death. Hannibal. Three years before this happened, he had written to Carthage to desire that young Hannibal, then twenty-two years of age, might be sent to him. This request was complied with, notwithstanding the opposition of Hanno; and, from the first arrival of the young man in the camp, he became the darling of the whole army. The great resemblance he bore to Hamilcar rendered him extremely agreeable to the troops. He seemed to possess every talent and qualification that contribute towards forming a great commander. After the death of Asdrubal, he was saluted as general by the army with the highest demonstrations of joy. He immediately put himself in motion; and in the first campaign conquered the Olcades, a nation situated near the Iberus. The next year he subdued the Vaccæi, another nation immediately adjoining. Soon afterwards, the Carpætani, one of the most powerful nations in Spain, declared against the Carthaginians. Their army consisted of 100,000 men, with which they proposed to attack Hannibal on his return from the Vaccæi; but by a stratagem they were utterly defeated, and the whole nation obliged to submit.

Nothing now remained to oppose the progress of the Carthaginian arms but the city of Saguntum, the modern Murviedro. Hannibal, however, for some time did not think proper to come to an open rupture with the Romans by attacking that place. At last he found means to embroil some of the neighbouring cantons, especially the Turdetani, or, as Appian calls them, the Torboletæ, with the Saguntines, and thus furnished himself with a pretext for attacking their city. Siege of Saguntum. On the commencement of the siege, the Roman senate dispatched two ambassadors to Hannibal, with orders to proceed to Carthage in case the general refused to give them satisfaction. But they had scarcely landed, when Hannibal, who was carrying on the siege of Saguntum with great vigour, sent them word that he had something else to do than to give audience to ambassadors. At last, however, he admitted them, and, in answer to their remonstrances, told them that the Saguntines had drawn their misfortunes upon themselves, by committing hostilities against the allies of Carthage; at the same time he desired the deputies, if they had any complaints to make of him, to carry them to the senate of Carthage. They did so, and on their arrival in that capital, demanded that Hannibal might be delivered up to the Romans, to be punished according to his deserts. This of course was not complied with, and war was immediately declared between the two nations.

The Saguntines are said to have defended themselves for eight months with incredible bravery. At last, however, the city was taken, and the inhabitants were treated with the utmost cruelty. After this conquest, Hannibal put his African troops into winter quarters at New Carthage; but, in order to gain the affection of the Spaniards, he permitted them to retire to their respective homes.

Hannibal sets out for Italy. The next campaign, having taken the necessary measures for securing Africa and Spain, he passed the Iberus, subdued the different nations betwixt that river and the Pyrenees, appointed Hanno commander of all the new conquered districts, and immediately began his march for Italy. Upon mustering his forces, after they had been weakened by sieges, desertion, mortality, and a detachment of 10,000 foot and 1000 horse left with Hanno to support him in his new post, he found them to amount to 50,000 foot and 9000 horse, all veteran troops, and the best in the world. As they left their heavy baggage with Hanno, and were all light armed, Hannibal easily crossed the Pyrenees; passed by Ruscino, a frontier town of the Gauls; and arrived on the banks of the Rhone without opposition. This river he passed, notwithstanding some opposition by the Gauls, and for some time remained in doubt whether he should advance to engage the Romans, who, under Scipio, had landed near the mouth of the Rhone, or continue his march for Italy. But he was soon induced to adopt the latter course by the arrival of Magilus, prince of the Boii, who brought rich presents with him, and offered to conduct the Carthaginian army across the Alps. Nothing could have happened more favourable to Hannibal's affairs than the arrival of this prince, since he possessed a local knowledge of the difficult region to be traversed, and there was no room to doubt the sincerity of his intentions; for the Boii bore an implacable enmity to the Romans, and had even come to an open rupture with them upon the first news that Italy was threatened with an invasion from the Carthaginians.

He crosses the Alps. It is not known with absolute certainty where Hannibal began to ascend the Alps, although the subject has been critically examined and discussed by many very able writers.[1] As soon as he began his march, the petty kings

[1] The commonly received opinion now is, that Hannibal, having passed the Rhone in the manner described by Polybius and Livy, advanced northwards along its left bank, cutting across the neck of the peninsula formed by the incurvation of the Rhone towards Lyons, but observing the general direction of the stream; that he then entered the *Insula Allobrogum*, a tract included between the Rhone and the Isère, which he traversed, still keeping a northerly direction; that having cleared the space between the two rivers, he turned off suddenly to the right, proceeded along the valley of the Isère, crossed the Alps by the Little St Bernard, and descended into Insubria, now Piedmont, between the Doria Baltea and the Orca. This route was first traced out by General Melville, who, with Polybius in his hand, surveyed the whole line of march, from the passage of the Rhone to the descent into Piedmont, and found it to agree in almost every particular with the account given by the military historian. As Polybius is remarkable for his general historical fidelity, and as he had himself personally investigated Hannibal's route little more than half a century after the Carthaginian commander had achieved his celebrated passage, his authority in this matter was justly assumed by the general as decisive; and hence, in order to discover what line Hannibal had actually followed, it was only necessary to find one which should, upon the whole, coincide better than any other with the description of Polybius. But of all the lines by which the Alps could have been crossed in the time of Hannibal, that of the Little St Bernard alone answered this condition; and, therefore, General Melville concluded that he had fully resolved the interesting question which he had proposed to himself in regard to this great achievement. The general himself, however, published nothing on the subject. He gave his notes to M. de Luc of Geneva, by whom they were very skilfully worked up into the form of a regular discourse, in which are embodied many additional illustrations of the general's theory, which are due to the learning and research of the redacteur himself. The same subject is treated with much ability and cogency of reasoning in the dissertation of Messrs Wickham and Cramer, which in fact comprehends all that is necessary to be known respecting it. With regard to the theory of Whitaker, who contends that Hannibal went round by Lyons, and crossed the Alps by the Great St Bernard, it is so demonstrably irreconcilable both with time and distance, to say nothing of insurmountable physical obstacles, that it carries its own refutation along with it. A new theory, differing in some respects from all former ones, has been proposed in a small volume recently published at Cambridge; but the anonymous author has failed as signally in the exposition of his own views of the subject, as in the attack he has thought proper to make, in no measured terms, on the joint production of Messrs Wickham and Cramer; and of the route he has proposed, it is sufficient to say, that it is impracticable in itself, and inconsistent with historical authority.

of the country assembled their forces in great numbers, and, taking possession of the eminences over which the Carthaginians must necessarily pass, continued harassing them, and were no sooner driven from one eminence than they seized on another, disputing every foot of ground with the enemy, and, by the local advantages they possessed, destroying great numbers of them. Hannibal, however, having found means to possess himself of an advantageous post, defeated and dispersed the enemy, and soon afterwards took their capital city, where he found the prisoners, horses, and baggage, that had before fallen into their hands, and likewise corn sufficient to serve the army for three days. At last, after a most fatiguing march of nine days, he arrived at the highest point in the route. Here he encamped, and halted two days, to give his wearied troops some repose, and to wait for the stragglers. But as the snow had recently fallen in great quantity, and covered the ground, this sight terrified the Africans and Spaniards, who were much affected with the cold. In order, therefore, to encourage them, the Carthaginian general led them to the top of the highest rock on the side of Italy, and thence gave them a view of the large and fruitful plains of Insubria, informing them that the Gauls, whose country they then beheld, were ready to join them. He also pointed out to them the place whereabout Rome stood, telling them, that by climbing the Alps they had scaled the walls of that rich metropolis; and, having thus animated his troops, he began to descend the mountains. The difficulties the troops met with in their descent were much greater than those which had occurred in the ascent. They had indeed no enemy to contend with, except some scattered parties who came to steal rather than to fight; but the deep snows, the mountains of ice, craggy rocks, and frightful precipices, proved more terrible than any enemy. After they had marched for some days through narrow, steep, and slippery pathways, they came at last to a place which neither elephants, horses, nor men could pass. The way, which lay between two precipices, was exceedingly narrow; and the declivity, which was naturally very steep, had still become more dangerous by the falling away of the earth. Here the guides stopped; and the whole army being terrified, Hannibal proposed at first to march round about, and attempt to turn the obstacle which appeared insurmountable; but all places around being covered with snow, he found himself reduced to the necessity of cutting a path into the rock itself, through which his men, horses, and elephants might descend. This work was accomplished with incredible labour; when Hannibal, having spent nine days in ascending, and six in descending the Alps, at length gained Insubria, and, notwithstanding the disasters he had met with by the way, entered the country with all the boldness of a conqueror.

Hannibal, on his entry into Insubria, reviewed his army, when he found that of the 50,000 foot with whom he had set out from New Carthage five months and fifteen days before, he had now only 20,000, and that his 9000 horse were reduced to 6000. His first care after entering Italy was to refresh his troops, who, after so long a march, and such inexpressible hardships, looked like as many skeletons raised from the dead, or savages born in a desert. He did not, however, suffer them to languish long in idleness; but, joining the Insubrians, who were then at war with the Taurinians, laid siege to Taurinum or Turin, the only city in the country, and in three days carried it by storm, putting all who resisted to the sword. This struck the neighbouring barbarians with such terror, that of their own accord they submitted to the conqueror, and supplied his army with all sorts of provisions.

Taurinum taken.

In the mean time, Scipio, the Roman general, who had been sent in quest of Hannibal to the Rhone, and who had even had an affair with his rear-guard on the banks of that river, was surprised to find that his antagonist had crossed the Alps and entered Italy. He therefore returned with the utmost expedition; and an engagement ensued near the river Ticinus, in which the Romans were worsted. The immediate consequence was, that Scipio repassed that river, and Hannibal continued his march to the banks of the Po, where he was detained two days before he could cross by means of a bridge of boats. He then sent Mago in pursuit of the enemy, who had rallied their scattered forces, repassed the Po, and encamped at Placentia. He next concluded a treaty with several of the Gallic cantons, and having joined his brother with the rest of the army, again offered battle to the Romans; but this they thought proper to decline; and at last the consul, intimidated by the desertion of a body of Gauls, abandoned his camp, passed the Trebia, and posted himself on an eminence near that river, where he drew lines round his camp, and waited the arrival of his colleague with the forces from Sicily.

Battle near the Ticinus.

Hannibal being apprised of the consul's departure, sent the Numidian horse in advance to harass him on his march, and himself moved at the head of the main body to support them in case of need. The Numidians arrived before the rear of the Roman army had quite passed the Trebia, and put to the sword or made prisoners all the stragglers they found there; and Hannibal coming up soon afterwards, encamped in sight of the Roman army on the opposite bank. Here, having learned the character of the consul Sempronius, who had lately arrived, he soon brought him to an engagement, and entirely defeated him. Ten thousand of the enemy retired to Placentia; but the rest were either killed or taken prisoners. The Carthaginians pursued the flying Romans as far as the Trebia, but did not think proper to repass that river, on account of the excessive cold.

Romans again defeated.

After this action upon the Trebia, Hannibal ordered the Numidians, Celtiberians, and Lusitanians, to make incursions into the Roman territories, where they committed great devastations. During his state of inaction, he endeavoured to win the affections of the Gauls, and likewise of the allies of the Romans, declaring to the Gallic and Italian prisoners, that he had no intention of making war upon them, being determined to restore them to their liberty, and protect them against the Romans; and to confirm them in a good opinion of him, he dismissed them all without ransom.

Next year, having crossed the Apennines, and penetrated into Etruria, Hannibal received intelligence that the new consul Flaminius lay encamped with the Roman army under the walls of Aretium; and having learned the true character of this general, who was of a haughty, fierce, and rash disposition, he doubted not of being soon able to bring him to a battle. In order to inflame the impetuous spirit of Flaminius, the Carthaginian general took the road to Rome, and leaving the Roman army behind him, laid waste with fire and sword the country through which he passed; and as that part of Italy abounded with all the elegancies as well as necessaries of life, the Romans and their allies suffered an incredible loss on this occasion. The headstrong consul was inflamed with rage at seeing the ravages committed by the Carthaginians, and therefore approached them with great temerity, as if confident of victory. Hannibal in the mean time kept still advancing towards Rome, having Crotona on the left, and Lake Thrasymenus on the right; and at last having drawn Flaminius into an ambuscade, entirely defeated him. The general himself, with fifteen thousand of his men, fell on the field of battle; a great number were taken prisoners; and a body of six thousand men, who had fled to a town in

Battle near Lake Thrasymenus.

Carthage.

Etruria, surrendered to Maherbal the next day. Hannibal lost only fifteen hundred men on this occasion, most of whom were Gauls; though great numbers both of his soldiers and of the Romans died of their wounds. Being soon afterwards informed that the consul Servilius had detached a body of four thousand, or, according to Appian, eight thousand horse, from Ariminum, to reinforce his colleague in Etruria, Hannibal sent out Maherbal, with all the cavalry, and some of the infantry, to attack him. The Roman detachment consisted of chosen men, commanded by Centenius, a patrician. Maherbal soon fell in with the enemy, and after a short contest entirely defeated them. Two thousand Romans were left dead on the spot; and the rest retiring to a neighbouring eminence, were surrounded by Maherbal's forces, and obliged next day to surrender at discretion. This disaster happening within a few days after the defeat at Lake Thrasymenus, gave almost the finishing stroke to the affairs of Rome.

Fabius Maximus appointed dictator.

The Romans being now in the utmost consternation, named a dictator, as was their custom in seasons of great emergency. The person they chose on this occasion was Fabius Maximus, surnamed Verruscosus, a man as cool and cautious as Sempronius and Flaminius were warm and impetuous. Fabius set out with a design not to engage Hannibal, but only to watch his motions and cut off his provisions, which he knew was the most proper way to destroy him in a country so far from his own. Accordingly he followed him through Umbria and Picenum into the territory of Adria, and then through the territories of the Marucini and Frentani into Apulia. When the enemy marched he followed them; when they encamped he did the same, but for the most part on eminences, and at some distance from their camp, watching all their motions, cutting off their stragglers, and keeping them in a state of continual alarm. This cautious method of proceeding greatly distressed the Carthaginians, but at the same time raised discontents in the Roman army. But neither these discontents, nor the ravages committed by Hannibal, could prevail upon Fabius to alter his measures. The former, therefore, entered Campania, one of the finest countries of Italy; and the ravages he committed there raised such complaints in the Roman army, that the dictator, for fear of irritating his soldiers, was obliged to pretend a desire of coming to an engagement. Accordingly he followed Hannibal with greater expedition than usual; but at the same time avoided, under various pretences, an engagement, with more care than the enemy sought it. Hannibal finding he could not by any means bring the dictator to a battle, resolved to quit Campania, which he found more abundant in fruit and wine than in corn, and to return to Samnium through the pass called Eribanus. Concluding from his march that such was his design, Fabius got there before him, and encamped on Mount Calicula, which commanded the pass, after having placed several bodies in all the avenues leading to it.

He is outwitted by Hannibal.

Hannibal was for some time at a loss what to do; but at last contrived a stratagem, which Fabius could neither foresee nor guard against. Being encamped at the foot of Mount Calicula, he ordered Asdrubal to pick out from among the cattle taken in the country two thousand of the strongest and nimblest oxen, to tie faggots to their horns, and to have them with the herdsmen ready without the camp. After supper, when all was quiet, the cattle were brought in good order to the hill, where Fabius had placed some Roman parties in ambush to stop up the pass. Upon a signal given the faggots upon the horns of the oxen were set on fire; and the herdsmen, supported by some battalions armed with small javelins, drove them on quietly. The Romans seeing the light of the fires, imagined that the Carthaginians were marching by torch-light. However, Fabius kept close in his camp, depending on the troops he had placed in ambuscade; but when the oxen, feeling the fire on their heads, began to run up and down the hills, the Romans in ambush thought themselves surrounded on all sides, and climbing the paths where they saw least light, returned to their camp, leaving the pass open to Hannibal. Fabius, though rallied by his soldiers for being thus overreached by the Carthaginian, still continued to pursue the same plan, marched directly after Hannibal, and encamped on some eminences near him.

Soon after this, the dictator was recalled to Rome; and as Hannibal, notwithstanding the ravages he had committed, had all along spared the lands of Fabius, the latter was suspected of holding a secret correspondence with the enemy. In his absence, Minucius, the general of the horse, gained some advantages, which greatly tended to increase the dissatisfaction with the dictator, insomuch that before his return Minucius was placed upon an equal footing with himself. The general of the horse proposed that each should command his day; but the dictator chose rather to divide the army, hoping by that means to save at least part of it. Hannibal soon found means to draw Minucius into an engagement, and, by his masterly skill in laying ambuscades, the Roman general was surrounded on every side, and would have been cut off with all his troops, had not Fabius hastened to his assistance, and relieved him. Then the two armies uniting, advanced in good order to renew the fight; but Hannibal, not caring to venture a second action, sounded a retreat, and retired to his camp; and Minucius, ashamed of his rashness, resigned the command of the army to Fabius.

Minucius relieved by Fabius.

Battle of Cannæ.

The year following the Romans augmented their army to 87,000 men, horse and foot, under the command of Æmilius Paulus and Terentius Varro, the consuls for the year; and Hannibal being reduced to the greatest straits for want of provisions, resolved to abandon Samnium and penetrate into the heart of Apulia. Accordingly he decamped in the night; and as he left fires burning, and tents standing in his camp, the Romans for some time believed that his retreat was only feigned. When the truth was discovered, Æmilius declared against pursuing him; but in this he was seconded by few besides Servilius, one of the consuls of the preceding year; Terentius and all the other officers being obstinately bent on pursuit. They accordingly overtook the enemy at Cannæ, till this time an obscure village in Apulia, and a battle ensued at this place, as memorable as any mentioned in history. In this desperate conflict the Romans, though almost twice the number of the Carthaginians, were put to flight with terrible slaughter, about 45,000 being left dead on the field of battle, and 10,000 taken prisoners in the action or pursuit. The night was spent in Hannibal's camp in feasting and rejoicings, and next day in stripping the dead bodies of the unhappy Romans; after which the victorious general invested their double camp, where he found 4000 men.

Consequences of the victory.

The immediate consequence of this victory, as Hannibal had foreseen, was a disposition on that part of Italy called the Old Province, Magna Græcia, Tarentum, and part of the territory of Capua, to submit to him. The neighbouring provinces likewise discovered an inclination to shake off the Roman yoke, but wanted first to see whether Hannibal was able to protect them. The latter, accordingly, being informed that the Hirpini and other neighbouring nations were disposed to enter into an alliance with the Carthaginians, marched into Samnium, and advanced to Compsa, which opened its gates to him. In this place he left his heavy baggage, as well as the immense plunder he had acquired; after which he ordered his brother Mago, with a body of troops destined for that purpose, to occupy all the fortresses in Campania, the most

Carthage.

delicious province of Italy. The humanity with which Hannibal had all along treated the Italian prisoners, as well as the fame of the complete victory he had lately obtained, wrought so powerfully upon the Lucani, Bruttii, and Apulians, that they expressed an eager desire of being taken under his protection; nay, even the Campanians themselves, a nation more obliged to the Romans than any in Italy except the Latins, discovered an inclination to abandon their natural friends. Of this the Carthaginian general received intelligence, and immediately bent his march towards Capua, not doubting but that, by means of the popular faction there, he should easily make himself master of the place, which he accordingly did. Soon after this place had submitted, many cities of the Bruttii opened their gates to Hannibal, who ordered his brother Mago to take possession of them. Mago was then dispatched to Carthage, with the important news of the victory at Cannæ, and the consequences attending it. Upon his arrival there, he acquainted the senate that Hannibal had defeated six Roman generals, four of whom were consuls, one dictator, and a general of horse; that he had engaged six consular armies, killed two consuls, wounded one, and driven another out of the field with scarcely fifty men to attend him; that he had routed the general of the horse, who was of equal power with the consuls; and that the dictator was esteemed the only general fit to command an army, merely because he had not the courage to engage him: and as a demonstrative proof of what he advanced, he produced, according to some authors, three bushels and a half of gold rings, taken from knights and senators who had been killed in the various engagements.

Capua submits to Hannibal.

Character of Hannibal.

Hitherto we have seen Hannibal almost uniformly victorious; and, indeed, if we call to mind what he had already done, we must consider his exploits as superior to those of any other general of ancient times. Other commanders have been celebrated for victories gained over barbarous and uncivilized nations. Alexander the Great, for instance, invaded and overran the empire of Persia; but that kingdom was then sunk in debasement and effeminacy; and if that great commander had turned his arms against the western nations, which were of a more martial disposition, it is more than probable he would not have conquered so easily. Hannibal, on the other hand, lived at a time when the Romans were not only the most powerful, but the most warlike nation in the world; yet that nation he attacked with an army of only 26,000 men, without resources either of recruits, money, or provisions, except what he could procure in the enemy's country. With these means he had for three years resisted the Roman armies, which had been hitherto invincible by all other nations. Their armies had been commanded by generals of different tempers, dispositions, and abilities; and the losses they had sustained were by the Roman writers imputed to the faults of the generals themselves; but experience had abundantly proved that these commanders, with all their defects, were able to conquer the most warlike nations when commanded by any one but Hannibal. In the battles fought with the Romans he had destroyed 200,000 of their men, and taken 50,000 prisoners. Yet from the time of the battle of Cannæ, the affairs of this great man totally declined. The reason of this, as stated by the Roman historians, is, that when he put his army into winter quarters in Capua, he so enervated himself and them by debaucheries in that place, that he became no longer capable of coping with the Roman forces. But this seems by no means to have been the case; for the Roman historians themselves own, that, after the battle of Cannæ, he gave their armies many severe defeats, and took a great number of towns in their sight.

Cause of the decline of his affairs.

The true cause of that reverse of fortune which Hannibal now experienced, was his not having sufficient resources for recruiting his army. On the first news, indeed, of his success at Carthage, a body of 4000 Numidian cavalry, 40 elephants, and 1000 talents of silver, were granted by the senate. A large detachment of Spanish forces was also appointed to follow them; and that these last might be ready in due time, Mago set out immediately for Spain to raise in that country 20,000 foot and 4000 horse. Had this ample supply been sent with proper expedition, it is by no means probable that the Romans would have had any occasion to reflect upon Hannibal's conduct at Capua; for that general would undoubtedly have obliged the haughty republic to submit to the superior force of his arms in the course of the next campaign. But, notwithstanding the influence of the Barcinian faction at Carthage, Hanno and his adherents found means not only to retard the march of the supplies intended, but even to diminish their number. Through the artifices of that infatuated party, Mago could obtain an order for only 12,000 foot and 2500 horse; and even with this inconsiderable body of troops he was sent into Spain. Hannibal being thus deserted by his country, found himself obliged to act upon the defensive; his army amounting now to little more than 26,000 foot and 9000 horse. But though obliged to act in this manner, he was only prevented from conquering; the utmost efforts of the Roman power were insufficient to drive this small army out of Italy in less than fourteen years.

Measures of the Romans.

The Romans, however, though greatly reduced, were not yet exhausted. They were still able to send two consular armies into the field, fully recruited and in good order; and as neither the Gauls nor Italians were natural allies of the Carthaginians, they did not fail to abandon them on the first reverse of fortune. After the Romans had recovered from the consternation into which they were thrown by the defeat at Cannæ, they chose a dictator, and recalled Marcellus, the conqueror of Syracuse, from Sicily. All the young Romans above seventeen years of age, of whatsoever rank, were obliged to enlist themselves; as were also those who had already completed their legal term of service. By these means four legions and 10,000 horse were soon raised in the city; while the allies of Rome, the colonies, and the municipia, furnished their contingents as usual. To these were added 8000 of the youngest and strongest slaves in the city, whom the republic purchased of their masters, but did not oblige to serve without their own consent, which they gave, by answering *Volo*, "I am willing;" and hence they were called *volones*, to distinguish them from the other troops. As the Romans, after the loss of so many battles, had no swords, darts, or bucklers, left in their magazines, the *volones* were supplied with the arms which had been formerly taken from the enemy and hung up in the public temples and porticoes. The finances of Rome were no less exhausted; but this defect was supplied by the liberality of her citizens. The senators showing the example, were followed first by the knights, and afterwards by the tribes; who, stripping themselves of all the gold they had, brought it to the public treasury. The senators only reserved their rings, and the *bullæ* about their children's necks. As for the silver coin, it was now, for the first time, alloyed with copper, and increased in value. Thus the finances were put into a tolerable condition, and a competent army raised.

This was plainly the last effort the Romans could make; and if Hannibal had procured a sufficient supply of men and money to enable him to cope with their new army, and to break it as he had done the others before, there would have been no more resistance on their part. He began, however, to be in want of money; and, in order to

Carthage.

procure it, gave the Roman prisoners permission to ransom themselves. These unhappy men agreed to send ten of their body to Rome to negotiate their redemption; and Hannibal required no other security for their return but their oath. Carthalo was sent at their head to make proposals of peace; but upon the first news of his arrival, the dictator dispatched a lictor to command him immediately to quit the Roman territory; and it was resolved not to redeem the captives. Upon this Hannibal sent the most considerable of them to Carthage; and of the rest he made gladiators, obliging them to fight with one another, even relations with relations, for the entertainment of the troops.

Asdrubal defeated by the Romans in Spain.

At this time Cneius and Publius Scipio carried on the war in Spain with great success against the Carthaginians. Asdrubal had been ordered to enter Italy with his army to assist Hannibal; but being defeated by the Romans, was prevented doing so. The dictator and senate of Rome, encouraged by this news, carried on the preparations for the next campaign with the greatest vigour, whilst Hannibal remained inactive at Capua. This inaction, however, seems to have proceeded from his expectation of succours from Africa, which never arrived; and this delay occasioned his ruin. The Roman dictator now released from prison all criminals, and persons confined for debt, who were willing to enlist themselves; and of these he formed a body of 6000 foot, armed with the broad swords and bucklers formerly taken from the Gauls. Then the Roman army, to the number of about 25,000 men, marched out of the city under the command of the dictator; whilst Marcellus kept the remains of Varro's army, amounting to about 15,000 men, at Casilinum, in readiness to march whenever there should be occasion for their services.

Thus the Roman forces were still superior to those of Hannibal; and as they now saw the necessity of following the example of Fabius Maximus, no engagement of any consequence happened during the first year after the battle of Cannæ. Hannibal made a fruitless attempt upon Nola, expecting it would be delivered up to him; but this was prevented by Marcellus, who had entered that city, and who, sallying unexpectedly from three gates upon the Carthaginians, obliged them to retire in great confusion, with the loss of 5000 men. This was the first advantage which had been gained by the Romans where Hannibal commanded in person, and it raised their spirits not a little. But they were as much dejected on learning that the consul Posthumius Albinus, with his whole army, had been cut off by the Boii, as he was crossing a forest. Upon this it was resolved to draw all the Roman forces out of Gaul and other countries, and turn them against Hannibal; so that the Carthaginian stood daily more and more in need of those supplies which as yet never arrived from Carthage. He, however, reduced the cities of Nuceria, Casilinum, Petelia, Consentia, Crotona, Locri, and several others in Magna Græcia, before the Romans gained any advantage over him, except that before Nola, already mentioned. The Campanians, who had espoused the Carthaginian interest, raised an army of 14,000 of their own nation in favour of Hannibal, and placed one Marius Alsius at the head of it; but the latter was surprised by the consul Sempronius, who defeated and killed him, with 2000 of his men. It was now found that Hannibal had concluded a treaty of alliance, offensive and defensive, with Philip king of Macedon; but, in order to prevent any disturbance from that quarter, a Roman army was sent to Macedon. Soon after this Marcellus defeated Hannibal in a pitched battle, having armed his men with long pikes, used generally at sea, and chiefly in boarding ships; by which means the Carthaginians were pierced through, while they were totally unable to hurt their adversaries with the short javelins they carried. Marcellus pursued them closely, and, before they got to their camp, killed 5000, and took 600 prisoners, losing himself about 1000 men, who were trodden down by the Numidian horse, commanded by Hannibal in person. After this defeat the Carthaginian general found himself deserted by 1200 of his best horse, partly Spaniards and partly Numidians, who had crossed the Alps with him. This touched him so sensibly, that he left Campania, and retired into Apulia.

Marcellus gains an advantage over Hannibal.

Hannibal takes several cities.

He is defeated by Marcellus.

The Romans still continued to increase their forces; and Hannibal, not having the same resources, found it impossible to act at once against so many armies. Fabius Maximus advanced into Campania, whither Hannibal was obliged to return, in order to save Capua. He ordered Hanno, however, at the head of 17,000 foot and 1700 horse, to seize Beneventum; but the latter was utterly defeated, and scarcely 2000 of his men were left alive. Hannibal himself, in the mean-time, advanced to Nola, where he was again defeated by Marcellus. He now began to lose ground on all sides. The Romans retook Casilinum, Accua in Apulia, Arpi, and Aternum; but the city of Tarentum was delivered up to him by its inhabitants. The Romans then entered Campania, and ravaged the whole country, threatening Capua with a siege. The inhabitants immediately acquainted Hannibal with their danger; but he was so intent upon reducing the citadel of Tarentum, that he could not be prevailed upon to march to their assistance. In the mean time Hanno was again utterly defeated by Fulvius, his camp taken, and he himself forced to fly into Bruttium with a small body of horse. The consuls then advanced with the design of besieging Capua in form. But, in their way, Sempronius Gracchus, a man of great bravery, and an excellent general, was betrayed by a Lucanian, and killed; which proved a very great detriment to the republic. Capua, however, was soon afterwards invested on all sides; and the besieged having once more sent to Hannibal, he now came to their assistance with his horse, his light-armed infantry, and thirty-three elephants. He also found means to apprize the besieged of the moment when he designed to engage the Romans, and to order them to make a vigorous sally in support of the attack. Upon the first news of the enemy's approach, the Roman generals, Appius and Fulvius, divided their troops; Appius taking upon him to make head against the garrison, and Fulvius to defend the intrenchments against Hannibal. The former found no difficulty in repulsing the garrison, and would have entered the city pell-mell along with them, had he not been wounded at the very gate, which prevented him from pursuing his design. Fulvius found it more difficult to withstand Hannibal, whose troops behaved with extraordinary resolution. A body of Spaniards and Numidians had even the boldness to pass the ditch, and, climbing the ramparts, in spite of all opposition penetrated into the Roman camp; but, not being properly seconded by the rest, they were cut off to a man. The Carthaginian general was so disheartened at this, especially after the garrison was repulsed, that he sounded a retreat, which was effected in good order. His next attempt for the relief of Capua was to march to Rome, where he hoped his approach would strike so much terror that the armies would be recalled from before Capua; and, that the Capuans might not be disheartened by his sudden departure, he found means to apprize them of his design. The news of his approach caused great consternation in the metropolis. Some of the senators were for recalling the armies from all parts of Italy to the neighbourhood of Rome, thinking nothing less sufficient to resist the terrible Carthaginian. But Fabius told them that Hannibal's design was not to take Rome, but relieve Capua; up-

Carthage.

on which Fulvius was recalled to Rome with 15,000 foot and 1000 horse; and this obliged Hannibal again to retire. He then returned so suddenly to Capua, that he surprised Appius in his camp, drove him out of it with the loss of a great number of men, and obliged him to intrench himself on some eminences, where he expected to be soon joined by his colleague Fulvius. As Hannibal, however, now expected to have all the Roman forces upon him, he could do nothing more for the relief of Capua, and consequently it at once was obliged to submit to the Romans.

Capua submits to the Romans.

Centenius Penula defeated by Hannibal;

A little before the surrender of Capua, Hannibal came up with a Roman army commanded by one M. Centenius Penula, who had signalized himself on many occasions as a centurion. This rash man, having been introduced to the senate, had had the assurance to tell them, that if they would entrust him with a body of only 5000 men, he would give a good account of Hannibal. They gave him 8000, and his army was soon increased to double that number. He engaged the Carthaginians on Hannibal's first offering him battle; but, after an engagement of two hours, he was defeated and slain, with all his men except about a thousand. Soon afterwards, having found means to draw the prætor Cneius Fulvius into an ambuscade, Hannibal cut in pieces almost his whole army, consisting of 18,000 men. In the mean time Marcellus was making great progress in Samnium, where the city of Salapia was betrayed to him; but he took two others by assault, in the last of which he found 3000 Carthaginians, whom he put to the sword, at the same time carrying off 240,000 bushels of wheat and 110,000 bushels of barley. This, however, was by no means a compensation for the defeat which Hannibal soon after inflicted on the proconsul Fulvius Centumalus, whom he surprised and cut off, with 13,000 of his men.

Fulvius Centumalus also defeated.

After this defeat Marcellus advanced with his army to oppose Hannibal; and various engagements took place, without any decisive result. In one of these the Romans are said to have been defeated, and in another Hannibal; but notwithstanding this, it was neither in the power of Marcellus nor of any other Roman general totally to defeat or disperse the army commanded by Hannibal in person. Nay, in the eleventh year of the war, Hannibal found means to decoy into an ambuscade and cut off Marcellus himself; the consequence of which was, that the Romans were obliged to raise the siege of Locri, with the loss of all their military engines.

Marcellus drawn into an ambuscade and killed.

Defeat of Asdrubal.

Hitherto the Carthaginians, though no longer the favourites of fortune, had lost but little ground; but now they met with a blow which totally ruined their affairs. This was the defeat of Asdrubal, Hannibal's brother, who had left Spain, and was marching to his assistance. He crossed the Pyrenees without any difficulty; and as the silver mines had supplied him with a great quantity of treasure, he not only prevailed upon the Gauls to grant him a passage through their territories, but likewise to furnish him with a considerable number of recruits. Meeting with many favourable circumstances to expedite his march, he arrived at Placentia sooner than either the Romans or his brother Hannibal expected. Had he continued to use the same expedition with which he set out, and hastened to join his brother, it would have been utterly impossible to save Rome; but, sitting down before Placentia, he gave the Romans time to concentrate their forces in order to attack him. At last he was obliged to raise the siege, and began his march for Umbria. He sent a letter to acquaint his brother of his intended movement; but the messenger was intercepted; and the two consuls, having formed a junction, fell upon the Carthaginians with their united forces. As the latter were inferior both in numbers and resolution, they were utterly defeated, and Asdrubal himself was killed. About the same time Hannibal is said to have suffered several defeats, and retired to Canusium; but on the fatal news of his brother's overthrow and death he was filled with despair, and withdrew to the extremity of Bruttium, where, assembling all his forces, he remained for a considerable time in a state of inaction, the Romans not daring to disturb him; so formidable did they esteem him alone, though every thing about him went to wreck, and the Carthaginian affairs seemed approaching the verge of ruin. Livy tells us, that it was difficult to determine whether his conduct was more wonderful in prosperity or in adversity. But notwithstanding this, Bruttium being a small province, and many of its inhabitants being either forced into the service, or forming themselves into parties of banditti, so that a great part of it remained uncultivated, he found it a difficult matter to subsist there, especially as no manner of supplies were sent him from Carthage. The people of that ill-fated republic were as solicitous about preserving their possessions in Spain, and as little concerned about the situation of affairs in Italy, as if Hannibal had met with an uninterrupted course of success, and as if no disaster had befallen him since he first entered that country.

Carthage.

Progress of Scipio Africanus.

All their solicitude, however, about the affairs of Spain was to no purpose; for their generals, one after another, were defeated by the Romans. They had indeed cut off the two Scipios; but they found a much more formidable enemy in the young Scipio, afterwards surnamed Africanus, who overthrew them in conjunction with Masinissa king of Numidia, who soon afterwards abandoned their interest; an example which was shortly after followed by Syphax king of the Masæsylii. Scipio also inflicted on the Spanish reguli, or petty princes, a great overthrow, and reduced the cities of New Carthage, Gades, and many other important places. At last the Carthaginians began to open their eyes, but it was now too late. Mago was ordered to abandon Spain, and sail with all expedition to Italy. He landed on the coast of Liguria with an army of 12,000 foot and 2000 horse, where he surprised Genoa, and also seized upon the town and port of Savo. A reinforcement was sent him to this place, and new levies went on very briskly in Liguria; but the opportunity was past, and could not be recalled. Scipio having carried all before him in Spain, passed over into Africa, where he met with no enemy capable of opposing his progress. The Carthaginians, then, seeing themselves on the brink of destruction, were obliged to recal their armies from Italy, in order to save their city. Mago, who had entered Insubria, was defeated by the Roman forces there; and having retreated into the maritime parts of Liguria, met a courier, who brought him orders to return directly to Carthage. At the same time Hannibal was likewise recalled. When the messengers acquainted him with the senate's pleasure, he expressed the utmost indignation and concern; groaning, gnashing his teeth, and scarce refraining from tears. Never did banished man, according to Livy, show so much regret in quitting his native country, as Hannibal evinced at leaving that of the enemy.

Scipio lands in Africa.

Mago and Hannibal recalled.

Hannibal's proceedings in Africa.

The Carthaginian general had no sooner landed in Africa than he sent out parties to procure provisions for the army, and buy horses to remount the cavalry. He entered into a league with the regulus of the Arcacidæ, one of the Numidian tribes; and four thousand of Syphax's horse came over in a body to him; but as he did not think proper to repose any confidence in them, he put them all to the sword, and distributed their horses amongst his troops. Vermina, one of Syphax's sons, and Macetulus, another Numidian prince, likewise joined him with a considerable body of horse; and most of the fortresses in Masinissa's kingdom either surrendered to him upon the first sum-

Carthage.

mons, or were taken by force. Narce, a city of considerable note, he obtained possession of by stratagem. Tychæus, a Numidian regulus, and faithful ally of Syphax, whose territories were famous for an excellent breed of horses, reinforced him also with 2000 of his best cavalry; and Hannibal advanced to Zama, a town about five days' journey distant from Carthage, where he encamped. He then sent out spies to observe the position of the Romans, and report. They were however made prisoners and brought before Scipio, who, far from inflicting any punishment upon them, which he might have done by the laws of war, commanded them to be led about the camp, in order that they might take an exact survey of it, and then dismissed them. Hannibal, admiring the noble confidence of his rival, sent a messenger to desire an interview with him, which, by means of Masinissa, he obtained. Escorted by equal detachments of horse, the two generals accordingly met at Nadagara, where, by the assistance of interpreters, they held a private conference. Hannibal flattered Scipio in the most refined and artful manner, expatiating upon all those topics which he thought calculated to influence that general to grant his nation a peace upon tolerable terms, and protesting that the Carthaginians would willingly confine themselves to Africa, since such was the will of the gods, in order to procure a lasting peace, whilst the Romans should be at liberty to extend their conquests to the remotest nations. Scipio answered, that the Romans were not prompted by ambition nor any sinister views to undertake either the former or present war against the Carthaginians, but by justice and a proper regard for their allies. He also observed, that the Carthaginians had, before his arrival in Africa, not only made him the same proposals, but likewise agreed to pay the Romans 5000 talents of silver, to restore all the Roman prisoners without ransom, and to deliver up all their galleys. He insisted on the perfidious conduct of the Carthaginians, who had broken a truce concluded with them; and added, that, so far from granting them more favourable, they ought to expect more rigorous terms, which, if Hannibal would submit to, peace might be concluded; if not, the decision of the dispute must be left to the sword.

His interview with Scipio.

The battle of Zama, and defeat of Hannibal.

This conference betwixt two of the greatest generals the world had ever produced thus ending in nothing, they retired to their respective camps, where they informed their troops, that not only the fate of Rome and Carthage, but that of the whole world, was to be determined by them the next day. An engagement ensued, in which, as Polybius informs us, the surprising military genius of Hannibal displayed itself in an extraordinary manner. Scipio likewise, according to Livy, pronounced a high encomium upon him, on account of his uncommon capacity in taking advantages, the excellent arrangement of his forces, and the manner in which he gave his orders during the engagement. The Roman general, indeed, not only approved his conduct, but openly declared that it was superior to his own. Nevertheless, being vastly inferior to the enemy in horse, and the state of Carthage obliging him to hazard a battle with the Romans at great disadvantage, Hannibal was utterly routed, and his camp taken. He fled first to Thon, and afterwards to Adrumentum, whence he was recalled to Carthage, where on his arrival he advised his countrymen to conclude a peace with Scipio, on whatever terms he thought proper to prescribe.

Peace concluded.

Thus was the second war of the Carthaginians with the Romans concluded. The conditions of peace were very humiliating to the Carthaginians. They were obliged to give up all the Roman deserters, fugitive slaves, prisoners of war, and all the Italians whom Hannibal had obliged to follow him. They also delivered over all their ships of war, except ten triremes, and all their tame elephants, and became bound not to train up any more of these animals for the service. They were not to engage in any war without the consent of the Romans. They engaged to pay to the Romans in fifty years 10,000 Euboic talents, in equal payments. They were to restore to Masinissa all they had usurped from him or his ancestors, and to enter into an alliance with him. They were also to assist the Romans both by sea and land whenever they were called upon to do so, and never to make any levies either in Gaul or Liguria. These terms appeared so intolerable to the populace, that they threatened to plunder and burn the houses of the nobility; but Hannibal having assembled a body of 6000 foot and 500 horse at Marthama, prevented an insurrection, and by his influence completed the accommodation.

Carthaginians oppressed by Masinissa.

The peace between Carthage and Rome was scarcely signed when Masinissa unjustly made himself master of part of the Carthaginian dominions in Africa, on the pretence that these had formerly belonged to his family. The Carthaginians, through the sinister mediation of the Romans, found themselves under the necessity of ceding these countries to that ambitious prince, and of entering into an alliance with him. An apparent good understanding between the two powers continued for many years afterwards; but at last Masinissa violated the treaties subsisting betwixt him and the Carthaginian republic, and not a little contributed to its subversion.

Hannibal flies to Antiochus.

After the conclusion of the peace, Hannibal still kept up his credit among his countrymen; and he was intrusted with the command of an army against some neighbouring nations in Africa; but this being disagreeable to the Romans, he was removed from it, and raised to the dignity of prætor in Carthage. Here he continued for some time, reforming abuses, and putting the affairs of the republic into a better condition; but as this likewise proved disagreeable to the Romans, he was obliged to fly to Antiochus, king of Syria. After his flight the Romans began to look upon the Carthaginians with a suspicious eye; though, to prevent every thing of this kind, the latter had ordered two ships to pursue Hannibal, had confiscated his effects, razed his house, and by a public decree declared him an exile. Soon afterwards, disputes having arisen between the Carthaginians and Masinissa, the latter, notwithstanding the manifest iniquity of his proceedings, was supported by the Romans. That prince, grasping at further conquest, endeavoured to embroil the Carthaginians with the Romans, by asserting that the former had received ambassadors from Perseus, king of Macedon; that the senate had assembled in the temple of Æsculapius in the night time, in order to confer with them; and that ambassadors had been dispatched from Carthage to Perseus, in order to conclude an alliance with him. Not long after this, Masinissa made an irruption into the province of Tysca, where he soon possessed himself of seventy, or, according to Appian, fifty towns and castles. This obliged the Carthaginians to apply with great importunity to the Roman senate for redress; their hands being so tied up by an article in the last treaty that they could not repel force by force, in case of an invasion, without their consent. Their ambassadors requested that the Roman senate would settle once for all what dominions they were to have, that they might from thenceforth know what they had to depend upon; or, if their state had in any way offended the Romans, they begged that the latter would punish them themselves, rather than leave them exposed to the insults and vexations of a merciless tyrant; and then prostrating themselves on the earth, they burst out into tears. But, notwithstanding the impression made by their speech, the matter was left undecided; so that Masinissa remained at liberty to pur-

Proceedings of Masinissa and the Romans.

Carthage. sue what course he pleased. But whatever designs the Romans might have entertained with respect to the republic of Carthage, they affected to show great regard to the principles of justice and honour. They therefore sent Cato, a man who scrupled not to commit enormities under the specious pretence of public spirit, into Africa, to accommodate all differences betwixt Masinissa and the Carthaginians. The latter very well knew their fate had they submitted to such a mediation; they therefore appealed to the treaty concluded with Scipio, as the only rule by which their conduct and that of their adversary ought to be tried. But this reasonable appeal so incensed the righteous Cato, that he pronounced them a devoted people, and from that instant resolved upon their destruction. For some time he was opposed by Scipio Nasica; but the people of Carthage knowing that the Romans were their inveterate enemies, and reflecting upon the iniquitous treatment which they had met with from them ever since the commencement of their disputes with Masinissa, were under great apprehensions of an invasion. To prevent a rupture as much as possible, they, by a decree of the senate, impeached Asdrubal, general of the army, and Carthalo, commander of the auxiliary forces, together with their accomplices, as guilty of high treason, and as being the authors of the war against the king of Numidia. They sent a deputation to Rome to discover what sentiments were entertained there of their late conduct, and to ascertain what satisfaction the Romans required; and their envoys meeting with a cold reception, others were dispatched, who returned with the same success. This led the unhappy citizens of Carthage to believe that their destruction was resolved upon, and consequently threw them into the utmost despair. And indeed they had but too just grounds for such a melancholy apprehension, as the Roman senate now discovered an inclination to adopt the measures suggested by Cato. About the same time the city of Utica, the second in Africa, and famous for its immense riches, as well as its commodious and capacious port, submitted to the Romans. On obtaining possession of so important a fortress, which, by reason of its vicinity to Carthage, might serve as a place of arms in the attack of that city, the Romans declared war against the Carthaginians without the least hesitation; and in consequence of this declaration, the consuls M. Manlius Nepos and L. Marcius Censorinus were dispatched with an army and fleet to commence hostilities with the utmost expedition. The land forces consisted of 80,000 foot and 4000 chosen horse; and the fleet of fifty quinqueremes, besides a vast number of transports. The consuls had secret orders from the senate not to conclude the operations but by the destruction of Carthage, without which, it was pretended, the republic could not but look upon all her possessions as insecure. Pursuant to the plan they had formed, the troops were first landed at Lilybæum in Sicily, whence, after receiving a proper refreshment, it was proposed to transport them to Utica.

War declared against Carthage.

Ambassadors sent to Rome.

The answer brought to Carthage by the last ambassadors had not a little alarmed the inhabitants of that city; but they were not as yet acquainted with the resolutions adopted at Rome. They therefore sent new ambassadors thither, whom they invested with full powers to act as they thought proper for the good of the republic, and even to submit themselves without reserve to the pleasure of the Romans. But the more sensible persons among them expected no great success from this condescension, since the early submission of the Uticans had rendered it infinitely less meritorious than it would have otherwise been. However, the Romans seemed to be in some measure satisfied with it, since they promised them their liberty, the enjoyment of their laws, and, in short, every thing that was dear and valuable to them. This threw them into a transport of joy, and they began to extol the moderation of the Romans. But the senate immediately dashed all their hopes, by acquainting them that this favour was granted upon condition of their sending three hundred young Carthaginian noblemen of the first distinction to the prætor Fabius at Lilybæum, within the space of thirty days, and complying with all the orders of the consuls. These hard terms filled the whole city with inexpressible grief; but the hostages were delivered, and as they arrived at Lilybæum before the thirty days were expired, the ambassadors were not without hopes of softening their hard hearted enemy. But the consuls only told them that upon their arrival at Utica they should learn the further orders of the republic.

Conduct of the Romans.

The ministers no sooner received intelligence of the Roman fleet appearing off Utica than they repaired thither in order to know the fate of their city. The consuls however did not judge it expedient to communicate all the commands of the republic at once, lest they should appear so harsh and severe that the Carthaginians would refuse to comply with them. They first, therefore, demanded a sufficient supply of corn for the subsistence of their troops; secondly, that the Carthaginians should deliver up into their hands all the triremes they were then masters of; thirdly, that they should put them in possession of all their military machines; and, fourthly, that they should immediately convey all their arms into the Roman camp.

As care was taken that there should be a convenient interval of time betwixt every one of these demands, the Carthaginians found themselves ensnared, and could not reject any one of them, though they submitted to the last with the utmost reluctance and concern. Censorinus, now imagining them incapable of sustaining a siege, commanded them to abandon their city, or, as Zonaras says, to demolish it; but kindly gave them permission to build another eighty stadia from the sea, but without walls or fortifications. This barbarous decree threw the senate and every one else into despair; and the whole city became a scene of horror, madness, and confusion. The citizens cursed their ancestors for not dying gloriously in the defence of their country, rather than concluding such ignominious treaties of peace, that had been the cause of the deplorable condition to which their posterity was then reduced. At length, when the first commotion had a little abated, the senators assembled, and resolved to sustain a siege. They were stripped of their arms, and destitute of provisions; but despair raised their courage, and made them find out expedients. They took care to shut the gates of the city, and gathered together on the ramparts great heaps of stones, to serve them instead of arms in case of a surprise. They released the malefactors from prison, gave the slaves their liberty, and incorporated them in the militia. They recalled Asdrubal, who had been sentenced to death only to please the Romans; and he was invited to employ in defence of his country 20,000 men whom he had raised against it. Another Asdrubal was appointed to command in Carthage; and all seemed resolute, either to save their city or perish in its ruins. They wanted arms; but, by order of the senate, the temples, porticoes, and all public buildings, were turned into workhouses, where men and women were continually employed in making arms. As they encouraged one another in their work, and lost no time in procuring to themselves the necessaries of life, which were brought to them at stated hours, they every day made 144 bucklers, 300 swords, 1000 darts, and 500 lances and javelins. As to balistæ and catapultæ, they wanted proper materials for them; but their industry supplied that defect. Where iron and brass were wanting, they made use of silver and gold, melting down the sta-

The Carthaginians resolve to sustain a siege.

Carthage. tues, vases, and even the utensils of private families; for on this occasion even the most covetous became liberal. As tow and flax were wanting to make cords for working the machines, the women, even those of the first rank, freely cut off their hair and dedicated it for that purpose. Without the walls, Asdrubal employed the troops in getting together provisions, and conveying them safely into Carthage; so that there was as great plenty there as in the Roman camp.

In the mean time the consuls delayed drawing near to Carthage, not doubting but the inhabitants, whom they imagined destitute of necessaries for sustaining a siege, would, upon cool reflection, submit; but at length, finding themselves deceived in their expectation, they appeared before the place and invested it. As they were still persuaded that the Carthaginians had no arms, they flattered themselves that they should easily carry the city by assault.

The city attacked, and the Romans repulsed.

Accordingly they approached the walls in order to plant their scaling ladders; but to their great surprise they discovered a prodigious multitude of men on the ramparts, shining in the armour which they had newly made. The legionaries were so terrified at this unexpected sight, that they drew back, and would have retired, if the consuls had not led them on to the attack, which, however, proved unsuccessful; the Romans, in spite of their utmost efforts, being obliged to abandon the enterprise, and lay aside all thoughts of taking Carthage by assault. In the mean time Asdrubal, having collected from all places subject to Carthage a prodigious number of troops, came and encamped within reach of the Romans, whom he soon reduced to great straits for want of provisions. As Marcius, one of the Roman consuls, was posted near a marsh, the exhalations of the stagnant waters, and the heat of the season, infected the air, and caused a general sickness among his men.

The Roman fleet destroyed.

Marcius, therefore, ordered his fleet to draw as near the shore as possible, in order to transport his troops to a healthier place. But Asdrubal being informed of this movement, ordered all the old barks in the harbour to be filled with faggots, tow, sulphur, bitumen, and other combustible materials; and then, taking advantage of the wind, which blew towards the enemy, let them drift against their ships, which were for the most part consumed. After this disaster, Marcius was recalled in order to preside at the elections; and the Carthaginians looking upon the absence of one of the consuls as a good omen, made a brisk sally in the night, and would have surprised the consul's camp, had not Æmilianus, with some squadrons, marched out by the gate opposite to the place where the attack was made, and, coming round, fallen unexpectedly on their rear, which obliged them to return in disorder to the city.

Asdrubal having posted himself under the walls of a city named Nepheris, twenty-four miles distant from Carthage, and situated on a high mountain, which seemed inaccessible on all sides, made incursions thence into the neighbouring country, intercepted the Roman convoys, fell upon their detachments sent out to forage, and even caused parties to insult the consular army in their camp. The consul, therefore, resolved to drive the Carthaginian from his advantageous position, and with this view set out for Nepheris. As he drew near the hills, Asdrubal suddenly appeared at the head of his army in order of battle, and fell upon the Romans with incredible fury. The consular army sustained the attack with great resolution; and Asdrubal retired in good order to his position, hoping the Romans would attack him there. But the consul, being now convinced of his danger, resolved to retire; which Asdrubal no sooner perceived than he rushed down the hill, and falling upon the enemy's rear, cut a great number of them to pieces. But the whole Roman army was saved by the bravery of Scipio Æmilianus. At the head of 300 horse he sustained the attack of all the forces commanded by Asdrubal, and covered the legions while they passed a river in their retreat before the enemy; after which he and his companions threw themselves into the stream, and swam across it.

The Roman army saved by Scipio Æmilianus.

When the army had crossed the river, it was perceived that four manipules were wanting; and soon after they were informed that these companies had retired to an eminence, where they resolved to sell their lives as dearly as possible. Upon receiving this intelligence, Æmilianus, taking with him a chosen body of horse, and provisions for two days, crossed the river, and flew to the assistance of his countrymen. He seized a hill over against that on which the four manipules were posted, and, after some hours' repose, marched against the Carthaginians, who kept them invested; fell upon them at the head of his detachment with the boldness of a man determined to conquer or die; and, in spite of all opposition, opened a way for his fellow-soldiers to escape. On his return to the army, his companions, who had given him over for lost, carried him to his quarters in a kind of triumph; and the manipules he had saved gave him a crown of *gramen*. By these and some other exploits, Æmilianus gained such reputation, that Cato, who is said never to have commended any body before, could not withhold from him the praises he deserved; and, moreover, foretold that Carthage would never be reduced till Scipio Æmilianus was employed in that expedition.

The next year the war in Africa fell by lot to the consul L. Calpurnius Piso; and he continued to employ Æmilianus in several important enterprises, which, under the conduct of the latter, were attended with uncommon success. He took several castles; and in one of his excursions found means to obtain a private conference with Phameas, general, under Asdrubal, of the Carthaginian cavalry; and brought him over, together with 2200 of his horse, to the Roman interest. Under the consul Calpurnius Piso himself, however, the Roman arms were unsuccessful. He invested Clupea, but was obliged to abandon the enterprise, with the loss of a great number of men killed by the enemy in their sallies. He then proceeded to vent his rage against a city newly built, and thence called Neapolis, which professed a strict neutrality, and had even a protection from the Romans. The consul, however, plundered the place, and stripped the inhabitants of all their effects. After this he laid siege to Hippagretta, which occupied the Roman fleet and army the whole summer; and, on the approach of winter, he retired to Utica, without performing a single action worth notice during the whole campaign.

The next year Scipio Æmilianus being chosen consul, was ordered to proceed to Africa; and, upon his arrival, the face of affairs was soon changed. At the time of his entering the port of Utica, 3500 Romans were in imminent danger of being cut in pieces before Carthage. They had seized upon Megalia, one of the suburbs of the city; but, as they had not furnished themselves with provisions to subsist there, and could not retire, being closely invested on all sides by the enemy's troops, the prætor Mancinus, who commanded the detachment, seeing the danger into which he had brought himself, dispatched a light boat to Utica to acquaint the Romans in that place with his situation. Æmilianus received his letter a few hours after landing, and immediately flew to the relief of the besieged Romans, obliged the Carthaginians to retire within their walls, and conveyed his countrymen safely to Utica. Having then drawn together all the troops, Æmilianus applied himself wholly to the siege of the capital.

His first attack was upon Megalia, which he carried by assault, the Carthaginian garrison retiring into the citadel of Byrsa. Asdrubal, who had commanded the Carthagi-

Carthage.

nian forces in the field, and now acted as governor of the city, was so enraged at the loss of Megalia, that he caused all the Roman captives taken in the two years during which the war had lasted to be brought upon the ramparts, and thrown headlong from the top of the wall; after having, with an excess of cruelty, commanded their hands and feet to be cut off, and their eyes and tongues to be torn out. He was of a temper remarkably inhuman; and it is said that he even took pleasure in seeing some of these unhappy men flayed alive. Æmilianus, in the mean time, was busy in drawing lines of circumvallation and contravallation across the neck of land which joined the isthmus on which Carthage stood to the Continent. By this means all the avenues on the land side of Carthage were shut up, so that the city could receive no provisions from the interior. His next care was to raise a mole in the sea, in order to block up the old port, the new one being already blockaded by the Roman fleet; and this great work he effected with immense labour. The mole reached from the western neck of land, of which the Romans were masters, to the entrance of the harbour, and was ninety feet broad at the bottom, and eighty at the top. The besieged, when the Romans first began this surprising work, laughed at the attempt; but they were no less alarmed than surprised, when they beheld a vast mole appearing above water, and the port thereby rendered inaccessible to ships, and useless. Prompted by despair, however, the Carthaginians, with incredible industry, dug a new basin, and cut a passage into the sea, by which they could receive the provisions which were sent them by the troops in the field. With the same diligence and expedition they fitted out a fleet of fifty triremes, which, to the great surprise of the Romans, appeared suddenly advancing into the sea through this new canal, and even ventured to give the enemy battle. The action lasted the whole day, with little advantage on either side. The day after, the consul endeavoured to make himself master of a terrace which covered the city on the side next the sea; and on this occasion the besieged signalized themselves in a most remarkable manner. Great numbers, naked and unarmed, plunged into the water in the dead of the night, with unlit torches in their hands; and having, partly by swimming, partly by wading, got within reach of the Roman engines, they struck fire, lit their torches, and threw them with fury against the machines. The sudden appearance of these naked men, who looked like so many monsters that had started out of the sea, so terrified the Romans who guarded the machines, that they began to retire in the utmost confusion. The consul, who commanded the detachment in person, and had continued all night at the foot of the terrace, endeavoured to stop his men, and even ordered those who fled to be killed. But the Carthaginians, perceiving the confusion among the Romans, threw themselves upon them like so many furies; and having put them to flight by means of their torches alone, they set fire to the machines, and entirely consumed them. This, however, did not discourage the consul; he renewed the attack a few days after, carried the terrace by assault, and effected a lodgment upon it with 4000 men. As this was an important post, because it hemmed in Carthage on the sea side, Æmilianus took care to fortify and secure it against the sallies of the enemy; and then, winter approaching, he suspended all further attacks upon the place till the return of good weather. During the winter season, however, the consul was not inactive. The Carthaginians had a very numerous army under the command of one Diogenes, strongly encamped near Nepheris, whence convoys of provisions were sent by sea to the besieged, and brought in by the new basin. To take Nepheris, therefore, was to deprive Carthage of her chief magazine. This Æmilianus undertook, and succeeded in the attempt. He first forced the enemy's intrenchments, put 70,000 of them to the sword, and made 10,000 prisoners; all the inhabitants of the country who were prevented from retiring to Carthage having taken refuge in this camp. After this he laid siege to Nepheris, which was reduced in twenty-two days. Asdrubal, disheartened by the defeat of the army, and touched with the misery of the besieged, who were now reduced to the utmost extremity for want of provisions, offered to submit to such conditions as the Romans pleased to dictate, provided the city were spared; but this was absolutely refused.

Carthage blockaded by sea and land.

The besieged set fire to the Roman machines.

Great slaughter of the Carthaginians.

Early in the spring Æmilianus renewed the siege of Carthage; and in order to open a passage into the city, he ordered Lælius to attempt the reduction of Cotho, a small island which divided the two ports. Æmilianus himself made a false attack on the citadel, in order to distract the enemy, and withdraw them from the place where the main effort was to be made. The stratagem had the desired effect; for the citadel being a place of the greatest importance, most of the Carthaginians hastened thither, and made the utmost efforts to repulse the aggressors; and in the mean time Lælius having, with incredible expedition, built a wooden bridge over the channel which divided Cotho from the isthmus, entered the island, scaled the walls of the fortress which the Carthaginians had built there, and made himself master of that important post. The proconsul, who was engaged before Byrsa, no sooner understood, by the loud shouts of the troops of Lælius, that he had made himself master of Cotho, than he abandoned the false attack, and unexpectedly fell on the neighbouring gate of the city, which he broke down, notwithstanding the showers of darts that were incessantly discharged upon his men from the ramparts. The approach of night prevented him from proceeding farther, but he effected a lodgment within the gate, and waited there for the return of day, with the design of advancing through the city to the citadel, and attacking it on that side, which was but indifferently fortified. Pursuant to this design, at daybreak he ordered four thousand fresh troops to be sent from the camp; and having solemnly devoted to the infernal gods the unhappy Carthaginians, he began to advance at the head of his men through the streets of the city, in order to attack the citadel. Having advanced to the market-place, he found that the way to the citadel lay through three exceedingly steep streets; while the houses on both sides were of great height, and filled with Carthaginians, who overwhelmed the Romans as they advanced, with darts and stones. It therefore became necessary first of all to clear the houses and streets. With this view Æmilianus in person, at the head of a detachment, attacked the first house, and made himself master of it, sword in hand. His example was followed by the officers and soldiers, who went on from house to house, putting all whom they met to the sword. As fast as the houses were cleared on both sides, the Romans advanced in order of battle towards the citadel, but met with a vigorous resistance from the Carthaginians, who on this occasion behaved with uncommon resolution. From the market-place to the citadel two bodies of men fought their way step by step; one above on the roofs of the houses, the other below in the streets. The slaughter was inexpressibly horrible. The air rung with shrieks and lamentations. Some were cut in pieces, while others threw themselves down from the tops of the houses; so that the streets were filled with dead and mangled bodies. But the destruction was yet greater when the proconsul commanded fire to be set to that quarter of the town which lay next to the citadel. Incredible multitudes who had escaped the sword of the enemy perished in the flames or by the fall of the

Cotho taken.

The Romans enter the city, and set it on fire.

Carthagena.

houses. After the fire had lasted six days, and consumed a sufficient number of houses, Æmilianus ordered the rubbish to be removed, and a large area to be made, where all the troops might have room to act. He then appeared with his whole army before Byrsa; which so terrified the Carthaginians, who had fled thither for refuge, that first twenty-five thousand women, and then thirty thousand men, came out of the gates in such a condition as moved pity even in the Romans, and threw themselves prostrate before the general, asking no favour but life. This was readily granted, not only to them, but to all that were in Byrsa except the Roman deserters, whose number amounted to nine hundred.

Cruelty and cowardice of Asdrubal.

Asdrubal's wife earnestly entreated her husband to suffer her to join the suppliants, and carry with her to the proconsul her two sons, who were as yet very young; but the barbarian denied her request, and rejected her remonstrances with menaces. The Roman deserters seeing themselves excluded from mercy, resolved to die sword in hand, rather than deliver themselves up to the vengeance of their countrymen. Finding them all resolved to defend themselves to the last breath, Asdrubal committed to their care his wife and children, after which, in a most cowardly and mean-spirited manner, he went privately and threw himself at the conqueror's feet. The Carthaginians in the citadel no sooner understood that their commander had abandoned the place, than they threw open the gates and put the Romans in possession of Byrsa. They had now no enemy to contend with but the nine hundred deserters, who, reduced to despair, retreated into the temple of Æsculapius, which formed a sort of second citadel within the first. There the proconsul attacked them; and these unhappy wretches, finding there was no way to escape, set fire to the temple. As the flames spread they retreated from one part of the building to another, till they got to the roof. There Asdrubal's wife appeared in her best apparel, and having uttered the bitterest imprecations against her husband, whom she saw standing below with Æmilianus, "Base coward," she exclaimed, "the mean things thou hast done to save thy life shall not avail thee; thou shalt die this instant, at least in thy two children." Having thus spoken, she stabbed both the infants with a dagger, and, while they were yet struggling for life, threw them from the top of the temple, and then leaped down after them into the flames.

His wife destroys herself and two children.

Carthage plundered and rased.

Æmilianus delivered up the city to be plundered, but in the manner prescribed by the Roman military law. The soldiers were allowed to appropriate to themselves all the furniture, utensils, and brass money, they should find in private houses; but all the gold and silver, the statues, pictures, and the like, were reserved in order to be put into the hands of the quæstors. On this occasion the cities of Sicily, which had often been plundered by the Carthaginian armies, recovered a number of statues, pictures, and other valuable monuments; amongst which the famous brazen bull which Phalaris had ordered to be cast, and used as the chief instrument of his cruelty, was restored to the inhabitants of Agrigentum. As Æmilianus was greatly inclined to spare what remained of this stately metropolis, he wrote on the subject to the senate, from which he received the following orders; 1. The city of Carthage, with Byrsa and Megalia, shall be entirely destroyed, and no traces of them left. 2. All the cities which have lent Carthage any assistance shall be dismantled. 3. The territories of those cities which have declared for the Romans shall be enlarged with the lands taken from the enemy. 4. All the lands between Hippo and Carthage shall be divided among the inhabitants of Utica. 5. All the Africans of the Carthaginian state, both men and women, shall pay an annual tribute to the Romans at so much per head. 6. The whole country formerly subject to the Carthaginian state shall be reduced into a Roman province, and be governed by a prætor, in the same manner as Sicily. Lastly, Rome shall send commissioners into Africa, there to settle jointly with the proconsul the state of the new province. Before Æmilianus destroyed the city, he performed those religious ceremonies which were required on such occasions; he first sacrificed to the gods, and then caused a plough to be drawn round the walls of the city. After this the towers, ramparts, walls, and all the works which the Carthaginians had raised in the course of many ages, and at a vast expense, were levelled with the ground; and, lastly, fire was set to the edifices of the proud metropolis, which were all consumed, not a single house escaping the flames. Though the fire began in many quarters at the same time, and burnt with incredible fury, it continued for seventeen days before all the buildings were consumed.

Thus fell Carthage, about 146 years before the birth of Christ; a city whose destruction ought to be attributed more to the intrigues of an abandoned faction, composed of the most profligate part of its citizens, than to the power of its rival. The treasure which Æmilianus carried off, even after the city had been delivered up to be plundered by the soldiers, was immense, amounting, according to Pliny, to 4,470,000 pounds weight of silver. The Romans ordered Carthage never to be inhabited again, denouncing dreadful imprecations against those who, contrary to this prohibition, should attempt to rebuild any part of it, especially Byrsa and Megalia. Notwithstanding this, however, about twenty-four years afterwards, C. Gracchus, tribune of the people, in order to ingratiate himself with the multitude, undertook to rebuild it, and for that purpose conducted thither a colony of 6000 Roman citizens. The workmen, according to Plutarch, were terrified by many unlucky omens at the time they were tracing the limits and laying the foundations of the new city; and the senate being informed of the circumstance, wished to suspend the attempt. But the tribune, little affected with such presages, continued to carry on the work, and finished it in a few days. Hence it is evident that only slight huts were erected in the first instance; but whether Gracchus executed his design, or whether the work was entirely discontinued, it is certain that Carthage was the first Roman colony ever sent out of Italy. According to some authors, Carthage was rebuilt by Julius Cæsar; and Strabo, who flourished in the reign of Tiberius, affirms, that in his time it was equal, if not superior, to any other city in Africa. It was looked upon as the capital of Africa for several centuries after the commencement of the Christian era. Maxentius laid it in ashes about the sixth or seventh year of Constantine's reign. Genseric, king of the Vandals, took it A. D. 439; but about a century afterwards it was re-annexed to the Roman empire by the renowned Belisarius. At last, towards the close of the seventh century, the Saracens, under Mahommed's successors, so completely destroyed it that there is now scarcely any trace or vestige of it remaining. (J.B—E.)

Rebuilt.

Utterly destroyed by the Saracens.

CARTHAGENA, a famous seaport and naval arsenal of Spain, in the province of Murcia. N. Lat. 37. 36.; W. Long. 1. 1. It occupies the site of the ancient *Carthago Nova*, the foundations of which were laid by Hasdrubal, the son-in-law and successor of Hamilcar Barca in Spain. It was the Carthaginian head quarters in Spain during the

Punic wars; and when taken at last by Scipio (B.C. 210), it received the name of *Colonia Victrix Julia Nova Carthago*, and continued to be a place of considerable importance under the Romans. For their cordage, they made copious use of the *spartum* or broom, which formerly supplied ropes for the navies of Spain, and still grows abundantly in the province. Its mines were wrought both by the Carthaginians and the Romans. To the Goths its maritime advantages presented few attractions, and accordingly the town was allowed by them to fall into decay. It was a flourishing port before the revolt of the Spanish colonies in America, but since that time its trade has been almost entirely destroyed; and the arsenals, from which the finest ships in the Spanish navy used to be equipped, have long been utterly deserted. The town itself is walled, and stands on the declivity of a hill, the centre of which is occupied by the ruins of an old Moorish castle. The houses are built of a fine red marble, and are mostly in the old Moorish style. The streets and pavements are generally very dilapidated, and the friable nature of the stone adds much to their ruinous appearance. Carthagena, being the see of a bishop, contains a cathedral, several churches and schools, hospitals, barracks, &c., but all of them partake of the general decay. The only feature that remains intact is the noble bay, land-locked on either side by high hills, and closed by the island *La Islota*, called also *La Escombrera*, from the mackerel (*scombri*) which are caught on the shore. The entrance is thus rendered very narrow, and is easily defended by forts planted on both heights and on the island. The trade of Carthagena is confined to the produce of the mines and fisheries, and the exportation of barilla. The abundance of raw material for the manufacture of glass induced an English company recently to start a factory. The town is rendered unhealthy by the existence of swamps in the neighbourhood, which breed fever and pestilence. Pop. 28,000.

CARTHAGENA, the capital of the republic of New Granada, South America. N. Lat. 10. 25.; W. Long. 75. 34. It is situated on a sandy island, on the shore of a large and very commodious bay more than two leagues in length. It contains a handsome cathedral, besides several churches, convents, and monasteries. The bay is closed in by another island, called Tierra Bomba, and to the eastward the city is joined by a bridge to a large suburb called Xiximani, which is connected with the continent by another bridge. The city and suburbs are well laid out, and the streets, though narrow, are straight and uniform. The houses are for the most part built of stone. They consist chiefly of one story above the ground floor. All of them have balconies and lattices of wood, which in that climate is more durable than iron. The climate is excessively hot, and the city suffers much from the ravages of yellow fever. In former times, this city was the scene of frequent contests, and in the late war of independence it was taken and retaken by both parties. The narrowness of the entrance to the harbour renders it easily defensible, and the fortresses on the islands are massive and well mounted with artillery. Its commercial facilities are great; but since the revolution its commerce has dwindled down to a mere transit trade, consisting of produce exported from the neighbouring districts, and the importation of manufactured goods in return. Pop. nearly 20,000.

CARTHUSIANS, a religious order, founded by St Bruno in the year 1084. (See BRUNO.) The Carthusians, so called from the desert of Chartreuse near Grenoble, the place of their institution, are remarkable for the austerity of their rules. They may not quit their cells, except to go to church, nor speak to any person without leave of their superior. Their beds are of straw, covered with a felt; their clothing consists of two hair-cloths, two cowls, two pairs of hose, and a cloak, all of coarse texture. In the refectory they are enjoined to keep their eyes on the dish, their hands on the table, their attention on the reader, and their hearts fixed on God. Bruno had given no particular rule to his disciples. Their code was first established in 1228, and was printed, with various additions and modifications, in 1581, under the title of *The Rule of Chartreux*. It was reprinted a century afterwards, and confirmed in 1682 by Innocent XI. In the middle of the eighteenth century, this order possessed in the several states of Europe 172 houses, divided into 16 provinces, each of which had two visitors. In this number were included four nunneries. There have been several canonized saints of this order, six cardinals, two patriarchs, fifteen archbishops, forty-nine bishops, and a great many very learned writers. They are a branch of the great order of Benedictines. The Charter House in London was a Carthusian monastery.

CARTOON (Italian *cartone*, pasteboard), in *Painting*, is a design drawn on thick paper, or other material, which is used as a model for a large picture in fresco, oil, or tapestry. It was also formerly employed in glass and mosaic work. Cartoons are employed in fresco-painting in the following manner: the back of the design is covered with black-lead or other colouring matter; and this side of the picture being applied to the wall, the artist passes over the lines of the design with a point, and thus obtains an impression. The following method has also been practised. The outlines of the figures are pricked with a needle, and the cartoon being placed against the wall, a bag of black colouring matter is drawn over the perforations, and the outlines are thus transferred to the wall. In fresco-painting, the figures were formerly cut out and fixed upon the moist plaster. Their contour was then traced with a pointed instrument, and the outlines appeared upon the plaster after the cartoon was withdrawn. In the manufacture of tapestries upon which it is wished to give a representation of the figures of cartoons, these figures are sometimes cut out, and laid behind or under the woof, to guide the operations of the artist. In this case the cartoons are coloured.

Cartoons have been executed by some of the most distinguished masters; but the greatest performances in this line of art are those of Raphael. They are seven in number, and at present adorn the palace of Hampton Court. With respect to their merits, they were allowed by Barry to be the best of Raphael's productions; and Lanzi pronounces them to be in beauty superior to anything the world has ever seen. Not that they are all endowed with features of perfect loveliness, and limbs of faultless symmetry; but in harmony of design, in the universal adaptation of means to one great end, and in the grasp of soul which they display, they stand unrivalled. The history of these extraordinary works is curious. In Catholic countries, particularly in Italy and Spain, the balconies are generally hung with ornamental tapestries upon festival days, when processions pass through the streets. This custom, which is still preserved, is of very old date. Leo X., that distinguished patron of the arts, employed Raphael in designing a series of Scriptural subjects, which were first to be finished in cartoons, and then to be imitated in tapestry by Flemish artists, and used for the purpose above mentioned. Two principal sets were accordingly executed at Arras in Flanders, but it is supposed that neither Leo nor Raphael lived to see them. The set which went to Rome was twice carried away by invaders, first in 1526, and afterwards in 1798. In the first instance they were restored in a perfect state; but after their return in 1814, one was wanting—the cupidity of a Jew having induced him to destroy it for the sake of the precious metal which it contained. Authorities differ as to their original number, but there appears to have been twenty-five of them. The cartoons after which the tapestries were woven were not, it would seem, restored to Rome, but remained as lumber about the manufactory till after the revolution of the Low Countries, when seven of them which had escaped destruction were purchased by Charles I., on

the recommendation of Rubens. They were found much injured, "holes being pricked in them for the weavers to pounce the outlines, and in other parts they were almost cut through by tracing." It has never been ascertained what became of the other cartoons. Of the seven which remain, various copies have been painted. Among the best are those by Sir James Thornhill in the Royal Academy. They have also been engraved.

CARTOUCHE (French, from the Latin *carta*), in *Architecture* and *Sculpture*, an ornament representing a scroll of paper. It only differs from a modillion in that the latter is set under the cornice in wainscotting, and the former under the cornice at the eaves of a house.

CARTOUCHE, in the military art, a case of wood, about three inches thick at the bottom, girt with marline, and containing about 400 musket balls, besides six or eight iron balls of a pound weight, to be fired from a howitzer, for the defence of a pass, &c.

A cartouche is sometimes made of a globular form, and filled with a ball of a pound weight: sometimes it is made for guns, and filled with balls of half or a quarter of a pound weight (according to the size of the gun), tied in the form of a bunch of grapes on a tompion of wood, and coated over. Cartouche likewise denotes a portable box for charges. (See CARTRIDGE-BOX.) Also a military pass given to a soldier going on furlough.

CARTOUCHE, in hieroglyphics, is the term applied by the French savans to the elliptical ring or oval which incloses every proper name in a monumental inscription. In the hieratic and demotic, enchorial, or civil forms of writing, the cartouche or oval degenerates into rude brackets.

CARTRIDGE, in the military art, a case of pasteboard or parchment, holding the exact charge of a fire-arm. The cartridges for muskets, carabines, and pistols, contain both the powder and ball. Those made for cannon and mortars are cases of pasteboard or tin, sometimes of wood; and simple flannel bags have been found convenient in practice.

CARTRIDGE-BOX, a case of wood or turned iron, covered with leather, with cells for holding a dozen or more cartridges. It is worn upon a belt thrown over the left shoulder, and hangs a little below the pocket-hole on the right side.

CARTWRIGHT, EDMUND, D.D., the inventor of the weaving machinery termed *The Power-loom*, was born April 24, 1743, at Marnham in Nottingham. He was educated at Magdalen College, Oxford, and was successively clergyman of Brampton in Derbyshire, and of Goadly Marwood in Leicestershire. He does not appear to have turned his attention to machinery until the year 1784, when he first conceived the idea of weaving by machinery; yet in April 1785 he produced his first *power-loom*, which he subsequently brought to perfection by numerous improvements. He took out no less than ten different patents connected with this process, one of which, dated in April 1790, was for the combing of wool. The first mill on his plan, which contained 500 of his looms, was destroyed by a wilful fire; and for 19 years, after a large expenditure, this great mechanical genius scarcely derived any advantage from his important inventions; but in 1809 parliament voted him a grant of L.10,000, as expressed in the act, "for the good service Dr Cartwright had rendered the public by his inventions for weaving." Though this sum was less than the money he had actually expended in perfecting his inventions, it rendered his latter days unembarrassed and comfortable. He died October 30, 1823, at the age of 80. It may be mentioned that he was the younger brother of Major John Cartwright, the well-known English Reformer of the reign of George III., to whose memory a bronze statue is erected in Burton Crescent, London.

CARTWRIGHT, *Thomas*, a celebrated Puritan divine, was born in Hertfordshire about the year 1535. He studied divinity at St John's College, Cambridge, but during the reign of Mary was compelled to adopt the legal profession. On the accession of Elizabeth, he resumed his theological studies, and was soon afterwards chosen Fellow of Trinity College. In 1570, he was chosen Margaret divinity professor; and it was during his occupation of this chair that his sentiments on ecclesiastical polity provoked the hostility of Sir William Cecil and Dr Whitgift, by the latter of whom he was deprived of his post in 1571. Immediately after this he removed to the continent, and officiated as clergyman to the English residents, first of Antwerp and afterwards of Middleburg. On his return, he became still further embroiled with Dr Whitgift and the government, and was several times thrown into prison, but always released at the intercession of his friends. He was finally liberated in 1592 and allowed to preach, but the hardships which he had previously endured brought on his death in 1603.

He wrote *A Confutation of the Rhemish translation, glosses, and annotations on the New Testament; Commentaria practica in totam Historiam Evangelicam; A Directory of Church Government; A Body of Divinity;* and also two expository works on Proverbs and Ecclesiastes.

CARTWRIGHT, *William*, a divine and poet of some eminence, was born at Northway, near Tewkesbury in Gloucestershire, in September 1611. He finished his education at Oxford, afterwards went into holy orders, and became a popular preacher in the university. In 1642 he obtained the place of succentor in the church of Salisbury, and was afterwards chosen junior proctor, and metaphysical reader in the university. His wit, judgment, elocution, combined with a graceful person and behaviour, elicited from Dr Fell the remark, "that he was the utmost that man could come to." He was an expert linguist, a good orator, and a respectable poet. His poems and plays were published in 1651. He died in 1643 of the fever called camp disease, which then prevailed.

CARUCATURIUS, in ancient law-books, he who held land in soccage, or by plough tenure.

CARUPANO, a seaport-town of Venezuela, in the province of Cumana, on the Caribbean Sea, not far from Cariaco. It is a place of some trade. Pop. about 8000.

CARVAGE (*carvagium*), the same with CARRUCAGE. Henry III. is said to have taken carvage, that is, two marks of silver for every knight's fee, towards the marriage of his sister Isabella with the emperor. Carvage could only be imposed on tenants *in capite*.

CARVAGE also denoted a privilege by which a person was exempted from the service of carrucage.

CARVER, a cutter of figures and other devices, especially in wood. In this sense carvers correspond to the Roman *sculptores*, who were distinct from the *cœlatores* or engravers, who wrought in metal. See CARVING.

CARVER also denotes one who cuts up the meat at table. The word is formed from the Latin *carptor*, which signifies the same. The Romans also called him *carpus*, *scissor*, and *structor*. In the great families at Rome the carver was an officer of some consequence; and there were masters to teach them the art regularly, by means of figures of animals cut in wood. The Greeks had also their carvers, or distributors. In primitive times the master of the feast carved for all his guests. Thus in Homer, when Agamemnon's ambassadors were entertained at Achilles's table, the hero himself carved the meat. In later times the same office was on solemn occasions performed at Sparta by some of the chief men. Some persons would derive the custom of distributing to every guest his portion from those early ages when the Greeks first learned the use of corn. The new diet was so great a delicacy that, to prevent the guests from quarrelling, it was found necessary to make a fair distribution.

CARVING, the art or act of cutting or fashioning any hard body, by means of a knife or chisel; but it is more particularly applied to the art of engraving or cutting figures.

in wood—in which sense, according to Pliny, it was prior both to statuary and painting.

CARWAR, a town of Hindustan, in the province of North Canara, presidency of Madras, situated in a bay at the mouth of a navigable river. It was formerly a noted seat of European commerce, and exported great quantities of cloth, but has lately fallen into decay. An English factory was established here in the year 1663, from which a contribution was levied in 1665 by Sevajee, the renowned founder of the Mahratta sway. During the reign of Tippoo the town fell completely into decay. Carwar was ceded to the British in 1779. It is 54 miles south by east of Goa. Long. 74. 16. E., Lat. 14. 49. N.

CARY, Lucius, second Viscount Falkland, a nobleman of great accomplishments, was born about 1610 at Burford in Oxfordshire, but as his father was lord-deputy of Ireland, he received his education at Trinity College, Dublin. He left the university to serve in the Low Countries; but being disappointed in obtaining promotion, he returned to England, and became an ardent student of literature. He made great progress in the study of the Greek and Latin historians and fathers, and lived in terms of intimacy with Johnson, Suckling, Cowley, and other celebrated literary men of the day. In 1633 he succeeded to his father's title, and was appointed gentleman of the privy-chamber to Charles I. In 1640 he took his seat in the House of Commons as member for Newport, Isle of Wight, and joined the parliamentary party in their resistance to the arbitrary measures of the king. He took a prominent part in the impeachment of Lord Finch, and in the endeavours to deprive the bishops of their seats in the House of Lords. On the breaking out of the civil war he raised and headed a troop in defence of the king, whom he attended at the battle of Edgehill, at Oxford, and the siege of Gloucester. He fell by a musket-shot in the battle of Newbury, leaving behind him a large collection of poems and political writings, which have since been published.

Cary, *Robert*, LL.D., a learned English chronologer, was born in Devonshire about the year 1615. On the restoration of Charles II., he was preferred to the archdeaconry of Exeter; but was ejected soon after, and spent the remainder of his days at his rectory of Portlemouth, where he died in 1688. He published *Palæologia Chronica*, a chronology of ancient times, in three parts, didactical, apodeictical, and canonical; and translated the church hymns into Latin verse.

CARYA or Caryatis, in Grecian antiquity, a festival celebrated yearly at Caryæ, a village of Laconia, in honour of Diana surnamed *Caryatis*. The chief ceremony was the performance by Lacedæmonian maidens of a lively kind of dance, said to have been first instituted by Castor and Pollux. When Xerxes invaded Greece, the Laconians did not appear before the enemy for fear of displeasing the goddess by omitting to celebrate her festival as usual; but the neighbouring swains assembled at the place and sung pastorals or *bucolismi;* to which circumstance some have referred the origin of bucolic poetry.

CARYATIDES, or Caryates. See Architecture.

CARYL, John, an English poet, was secretary to Queen Mary, the wife of James II., and followed the fortunes of his abdicated master, by whom he was rewarded with the honorary titles of Earl Caryl and Baron Dartford. He was in England in the reign of Queen Anne, and recommended the subject of the Rape of the Lock to Pope, who dedicated it to him. The last of his works, which consisted of a translation of the Psalms, was published in 1700; and he was still alive in 1717.

Caryl, *Joseph*, a nonconformist divine (1602–1673), was educated at Oxford, and held for some time the office of preacher to the society of Lincoln's Inn. He frequently preached before the long parliament, and held several important offices among the nonconformist clergy. He was a licenser of their theological books, one of the assembly of divines, and one of the board for the approbation of ministers. On the restoration of Charles II. he was silenced by the Act of Uniformity, but continued to preach privately in London, where, besides other works, he wrote an *Exposition of the Book of Job*.

CARYOTA, a genus of plants of the order of Palmæ, of which two species are described—*C. urens*, a native of India, and *C. horrida*, of South America. The *C. urens* is described by Dr Roxburgh as a very valuable tree. The yellow berry, which is about the size of our plum, is intensely acrid if applied to the skin; but the stem, during the hot season, yields *Toddy*, the material from which palm wine is made; and the pith affords an excellent sago, much used by the Indians.

CASA, Santa, the chapel of the Holy Virgin at Loretto. The *Santa Casa* is properly the chamber in which the blessed Virgin is said to have been born, where she was betrothed to Joseph, where the angel saluted her, and where the Son of God was incarnated. Of this building the Catholics relate many wonderful legends. See Loretto.

CASAL MAGGIORE, a town of Lombardy, in the delegation of Cremona, on the Po, twenty-two miles E.S.E. of Cremona. It has a gymnasium, hospital, two orphan asylums, theatre, and manufactures of glass, earthenware, and cream of tartar. Pop. 5000.

CASALE, one of the provinces into which the kingdom of Sardinia is divided. It is bounded north and east by Vercelli and Mortara, south by Alessandria, and west by Asti and Turin. It has an area of 340 square miles, and a population (1848) of 120,425, most of whom are engaged in the culture of the vine, the tending of sheep, and the production of silk.

Casale, the capital of the above province, is situated on the right bank of the Po, 38 miles east from Turin. It was anciently a strong fortress, but has been recently (1849) still further strengthened and improved. It is the see of a bishop, and contains a very ancient cathedral. Its churches are possessed of several fine works of art; and that of San Domenico, in which is the tomb of the Paleologhi, is remarkable for the elegance of its design. Among its other buildings are an ancient clock-tower, several palaces of the nobility, a college, and a theatre. The courts of justice for the province are held here. The only manufacture is that of silk. The population is rather more than 20,000.

CASALNUOVO, a town of Naples, province of Calabria Ultra I., 18 miles E.S.E. of Gioja. It is pleasantly situated at the foot of the mountains in a rich olive district, and has about 8000 inhabitants. The town was almost totally destroyed by an earthquake in 1783.

CASAR-de-Caceres, a Spanish town in the province of Estremadura, with 5000 inhabitants, who enjoy a partial freedom, and have among themselves rather a democratical constitution. The tanning of leather is the chief employment here.

CASAS, Bartolommeo de Las, bishop of Chiapa in Mexico, was born of a noble family at Seville in 1474. At the age of nineteen he went to St Domingo with his father, who had accompanied Columbus in his first voyage. Soon after his return he entered the order of Dominicans, with the view of being employed as a missionary to the Indians. In 1533 we find him residing in the island of St Domingo, where, as we learn from Oviedo Valdes, he was successful in putting an end to the wars which had raged between the Spanish settlers and the Indians in consequence of an outrage committed on the wife of their chief in 1519. This peace, however, proved but of short duration, and was followed by the massacre of nearly all the natives.

Before this time Las Casas had presented to Charles V. several memoirs in favour of the Indians; but finding his

efforts in this direction fruitless, he proposed to found a colony, and prevailed on the emperor to appoint him governor of Cumana. He set sail with 300 Castilian emigrants, whom he distinguished by the badge of the white cross, and arrived at Porto Rico in 1519, but immediately after sailed for Cumana. On his arrival there, Gonzalo Ocampo, commandant of the place, refused to recognise his authority, and Las Casas was compelled to repair to St Domingo to lay his case before the governor-general. In his absence the Indians massacred all the colonists except a few who escaped to the small island of Cubagna, and the colony became extinct. His zeal on behalf of the Indians led him several times to Spain, and provoked a hostile attack from Sepulveda, canon of Salamanca, and historiographer to Charles V. The emperor prohibited the publication of this memoir; but it was nevertheless printed at Rome, and circulated throughout Spain by the monks. It was refuted by Las Casas, then bishop of Chiapa, in a work entitled "Brevissima Relacion de la Destruccion de las Indias;" and although Sepulveda still pressed his accusation before the emperor, he procured no decision.

The devotion of Las Casas to the cause of the Indians gave rise to the accusation which has been revived by modern historians, that he recommended to the Spaniards the trade in negroes, in order to substitute the blacks for the Indians in the labours of the colonies. But M. Grégoire, in a memoir entitled *Apologie de B. de Las Casas*, inserted in the fourth volume of the *Mémoires de la Classe des Sciences Morales et Politiques de l'Institut*, has refuted this imputation. In addition to this, there are still extant three manuscript volumes in folio containing the memoirs, official and familiar letters, political and theological works, of Las Casas, which show that the author deeply compassionated the sufferings of the African race.

The works of Las Casas are, 1. *Brevissima Relacion de la Destruccion de las Indias;* 2. *Principia quædam ex quibus procedendum est in disputatione, ad manifestandam et defendendam justitiam Indorum;* 3. *Utrum reges et principes, jure aliquo vel titulo et salva conscientia cives ac subditos a regia corona alienare et alterius dominii particularis ditioni subjicere possint?* Frankfort, 1571; 4. Various tracts and pieces on theology and morals. The original edition of *Las Obras de D. Barth. de Las Casas*, Seville, 1552, was printed in Gothic characters, and is very scarce.

CASATI, Paul, a learned Jesuit (1617–1707), born at Placentia. After having taught mathematics and divinity at Rome, he was sent into Sweden to Queen Christina, and prevailed on her to embrace the popish religion. He afterwards presided over the university of Parma. He wrote, 1. *Vacuum proscriptum;* 2. *Terra machinis mota*, Rome, 1668, 4to; 3. *Mechanicorum libri octo;* 4. *De Igne Dissertationes*, Parma, 1686 and 1695, 2 vols. 4to; 5. *De Angelis Disputatio Theologica;* 6. *Hydrostaticæ Dissertationes;* 7. *Opticæ Disputationes.* The last mentioned treatise he wrote at the age of 88, and after he was blind.

CASAUBON, Isaac de, was born at Geneva, on the 18th February 1559; his family, which was originally from Dauphiné, having taken refuge in that city after embracing the Reformed religion. He received the rudiments of his education from his father, who was latterly minister of Crest; and his progress was so rapid that at the age of nine he spoke Latin with correctness and fluency. At the age of nineteen he entered upon his academical course at Geneva; and having devoted himself to the study of jurisprudence, theology, and the oriental languages, in 1582 he succeeded his master, Francis Portus, in the chair of Greek. He married Florence, daughter of M. Etienne; and in 1596 accepted the chair of Greek and belles-lettres at Montpellier, where, however, as his salary was ill paid, he remained only two years. He was soon after appointed by Henry IV. to a similar situation in Paris; but his religion, the jealousy of the other professors, and perhaps also his untractable temper, produced misunderstandings and occasioned inconveniences, for which, however, he was indemnified by being appointed librarian to the king, with a salary of four hundred francs. He was one of the commissioners at the conference of Fontainebleau, between Cardinal Du Perron and Duplessis-Mornay, and gave his opinion in favour of the former and against the latter. It is known, indeed, that on various important points he dissented from the tenets of the Reformed church; and he was even suspected of a disposition to reconcile himself to the ancient religion; a suspicion which was strengthened when his son embraced the Romish religion, and became a Capuchin. After the death of Henry IV. Casaubon went to England with Sir Henry Wotton, ambassador extraordinary of King James I., and was received with great favour by that monarch, who gave him two prebends, one at Canterbury and the other at Westminster, and also conferred on him a pension of L.200. Casaubon now established himself in England, and died at London on the 1st of July 1614. He was buried at Westminster, where a monument was erected to his memory. The Protestants of France always doubted the sincerity of his attachment to their party: and Pierre Dumoulin, writing to Montague bishop of Bath, said that Casaubon had a great inclination towards popery, and predicted that he would end by changing his religion. This prediction, however, was not verified. Casaubon was an able theologian, a scholar of the first order, a good translator, and an excellent critic. Pithou, De Thou, Heinsius, Grævius, Duperron, and other learned men, have all given him the same character. His Latin is slightly deformed by Gallicisms, and his historical works are not free from inaccuracies. A complete list of his works would of itself fill several columns.

The principal are, 1. *In Diogenem Laërtium Notæ*, 1583, 8vo; 2. *Polyæni Stratagematum, Gr. et Lat. cum Notis Casauboni*, Lyons, 1589, 8vo; 3. *Aristotelis Opera, Gr. et Lat.* Lyons, 1590; 4. *Theophrasti Characteres, Gr. et Lat.* Lyons, 1622; 5. *Suetonii Opera, cum animadversionibus*, Paris, 1606, 4to; 6. *Persii Satyræ, cum Comment.* Paris, 1608, 8vo; 7. *Polybii Opera, Gr. et Lat.* Paris, 1609; 8. *De Satyrica Græcorum Poesi et Romanorum Satyra, libri duo*, Paris, 1605, 8vo; 9. *Exercitationes contra Baronium*, London, 1614, folio; 10. *De Libertate Ecclesiastica, liber singularis*, 1607; 11. *Ad Frontonem Ducæum Epistola*, London, 1611; 12. *Casauboni Epistolæ*, the best edition of which is that of Ameloveen, Rotterdam, 1709.

Casaubon, *Meric*, son of the preceding, was born at Geneva on the 14th of August 1599. He commenced his studies at the Protestant academy of Sedan, but when his father settled in England, he was sent to Christ College, Oxford, and took the degree of M.A. in 1621. He was successively appointed curate of Bledon, Somersetshire, prebendary of Canterbury, and rector of Wickham, and obtained the degree of D.D. from Oxford; but was stripped of his preferments at the Revolution. Cromwell wished him to engage in writing a history of the civil wars, and offered him a gratuity of L.400 to assist him in the undertaking; but Casaubon, whose sentiments were unfavourable to the protector, rejected both the proposal and the gift. He refused also a proposal from Queen Christina, who was anxious to appoint him to a high professional office in her dominions. At the Restoration he was rewarded for his fidelity by being reinstated in all his benefices, which he enjoyed till the period of his death in July 1671. He was interred in the cathedral of Canterbury, where a monument was erected to his memory. Casaubon was a pious man, charitable to the poor, of an honest and affable character, and ever ready to communicate the result of his researches. He applied himself principally to criticism, and his erudition was varied, though far from being so profound as that of his father. To the philosophy of Descartes he ascribed the decline of the taste for the belles-lettres, which formed one of the characteristics of his time.

His principal works are, 1. *Optati Milevitanti libri vii., cum notis et emendationibus*, London, 1631, 8vo; 2. *Notæ et Emendationes in*

M. Antonini libros xii., ibid. 1643, 8vo: 3. *De Verborum Usu et accurata eorum Cognitionis utilitate Diatribe*, 1647, 12mo; 4. *De quatuor Linguis Commentationis pars prior*, 1650, 8vo; 5. *De la Necessité de la Réformation au temps de Luther*, London, 1664; 6. *De la Crédulité et de l'Incrédulité*, 1668 and 1670, 8vo; 7. *La Cause première des Biens et des Maux qui arrivent en ce Monde*, 1642, 4to; 8. *Traité de l'Enthousiasme*, 1655, 8vo; 9. *Veritable et fidèle Rélation de ce qui s'est passé entre Jean Dée et certains Esprits*, 1659, folio; 10. *Défense de l'Oraison Dominicale*, 1669, in reply to Dr Owen. He was also the author of several productions on ecclesiastical subjects, and of notes on Terence, Epictetus, Hierocles, Florus, Diogenes Laertius in the edition of Meibomius, Polybius in the edition of Gronovius, and Persius in the London edition, 1647, 8vo. He left a great number of manuscripts, which are preserved at Oxford.

CASBIN, or CASWEEN, a city of Persia, in the province of Irak. It is situated on a large sandy plain or valley to the S.W. of the lofty ridge of the Elburz. Although the greater portion of it was thrown down by an earthquake, it is still regarded as one of the largest and most populous towns in the kingdom, and carries on a great trade with Ghilan. It is built in the form of a square, each side of which is about a mile long, and surrounded by a wall. There is a palace here built by Nadir Shah, adjoining an old one erected by Shah Abbas the Great. It became the capital of Persia during the reigns of the immediate predecessors of this latter monarch; and when visited by Chardin in 1674, contained many magnificent buildings, which are now mostly in ruins. It has manufactures of carpets of different colours, which are in high repute, and also of sword blades; and still carries on a considerable trade with Georgia, Azerbijan, Ghilan, and the Caspian Sea. The population is estimated at 60,000. E. Long. 49. 33., N. Lat. 36. 12.

CASCADE (French *cascade*, Italian *cascáta*, from *cascáre*, to fall, from the Latin *cadere*), a waterfall, either natural or artificial. The word is applied to falls that are less than a cataract.

CASCAES, a small seaport-town of Portugal, in the province of Estremadura, 15 miles west of Lisbon. Pop. about 3000, principally fishermen.

CASCARILLA, a bitter tonic bark, the produce of *Croton Eleuteria*, and probably of other species of Croton.

CASE (Latin *casus*, from *cado*, I fall), in *Grammar*, the inflection of nouns, or a change of termination, serving to express the different relations they bear to each other, or to the things they represent. All cases except the nominative are called oblique cases.

CASE, in *Printing*, a large flat oblong frame or box, placed aslope, and divided into numerous little square compartments, each containing a number of types of the same kind, whence the compositor takes the particular letters he requires in composing his matter. See PRINTING.

CASE-Shot, in the military art, musket-balls, stones, old iron, &c., put into cases, and shot out of great guns.

CASE-HARDENING, the process of converting the superficies or outer part of iron into steel. This is effected by placing the article in a box with some animal or vegetable charcoal, and exposing it to a red heat. It differs only from the making of steel in the shorter duration of the process. Iron tools, &c., when thus treated, combine the toughness of iron with the hardness of steel.

CASERTA, a town of Naples, capital of the province of Terra di Lavoro, stands in a fine plain 17 miles N.E. of Naples, and 6 miles E.S.E. of Capua. It has about 5000 inhabitants, and is principally noted for its palace and aqueduct, both constructed by Vanvitelli for Charles III. The palace, which is reputed one of the most magnificent royal residences in Europe, is a rectangular building, in the richest style of Italian architecture. The length of the front on the south side is about 780 feet, and the height 125 feet, with five stories, each with a row of 37 windows; the gardens are adorned with numerous cascades supplied with water by an aqueduct upwards of 21 miles long from the skirts of Monte Taburno.

CASHAN, or KASHAN, a flourishing city of Persia, 92 miles north of Ispahan, situated in a stony plain, and very ill supplied with water. N. Lat. 33. 55., E. Long. 51. 20. The manufactures of silks, carpets, cottons, and gold and silver articles, are extensive. It has a palace, and many fine mosques, bazaars, and caravanserais. Pop. probably 30,000.

CASHEL, an inland city and parliamentary borough in the county of Tipperary, Ireland, with a population in 1851 of 4798. The town is rather handsome, with a wide and well built main street, but has been far from prosperous, probably for want of the requisite means of communication with other parts of the country. The chief object of interest is the "Rock of Cashel," which may be seen from a distance of many miles, and which commands a beautiful prospect over the city and the county of Tipperary. This rocky elevation, covered with the most beautiful grass, rises abruptly out of the plain, and stands close to the town. On its summit is the finest assemblage of ruins in Ireland. They consist of the ancient cathedral, the largest and most remarkable ecclesiastical remains in the country; Cormack's chapel, considered to be the oldest stone building in Ireland; and a round tower which differs in the material of which it is composed from all that surrounds it—the other ruins and the rock itself being of limestone, whilst the round tower is built of freestone. The chief buildings in the city are the new cathedral, a spacious modern church; the palace attached to the see, now converted into a deanery house; the Roman Catholic chapel; the market-house; court-house, &c. Cashel, formerly an archiepiscopal see, was reduced to a bishopric by the Church Temporalities act in 1833; and the bishop now resides at Waterford. It returns one member to parliament, and was formerly a corporate town, but the corporation was extinguished by the Municipal Reform act. Constituency in 1853, 126. The Great Western railway passes within 6 miles of the town, which is distant 108 miles S.W. from Dublin. (H. S—R.)

CASHEW (*Anacardium occidentale*), a tree of the West Indies, bearing a kidney-shaped nut attached to the apex of the receptacle, which is as large as an orange. The nut contains an acrid oil, which renders it uneatable till it has been well roasted in the fire. This oil or juice is used as a black dye; and as a marking-ink for linen it is very durable.

CASHIER, a cash-keeper; he who receives and pays the debts of a society. In the generality of foundations the cashier is called *treasurer*. In a banking institution the cashier is the officer who superintends the books, payments, and receipts of the bank. He also signs or countersigns the notes, and superintends all the transactions, under the order of the directors.

CASHMERE, a kingdom in northern India, so called from its principal division, the celebrated valley of that name; and comprehending within its limits the various territories which constitute the dominions of Gholab Singh. Its boundaries are the Karakorum mountains on the north; Thibet on the east; the British possessions of Spiti, Lahoul, and the Punjaub on the south; and the Huzareh country on the west. It extends from Lat. 32. 17. to Lat. 36., and from Long. 73. 20. to Long. 79. 40.; its extreme length from east to west being 350 miles, and its breadth about 270. Area about 25,000 square miles. The population has been estimated at 750,000. Within its limits are included the valley of Cashmere, and the provinces of Jamoo, Ladahk, Bulti or Iskardoh, Chamba, and some others.

The valley of Cashmere is a tract of oval form, surrounded by lofty mountains. Its extent from the snowy Panjal on the S.E. to the Durawar ridge on the north measures 120 miles, with a breadth of 65 miles in the direction of the opposite angles. This country is universally celebrated in the east for its romantic beauties, its fertile soil, and tempe-

 rate climate. According to ancient tradition, the valley, inclosed by mountains rising above the limit of perpetual snow, was the bed of a great lake, into which flowed all the streams from the adjacent hills, carrying with them large quantities of soil. The lake at last opening itself a passage through the mountains, left the valley covered with a rich alluvial deposit, an admirable field for human industry. The valley of Cashmere is not exposed to the periodical rains which deluge the rest of India, the clouds being shut out by the height of the mountains; and it has only light showers. These, however, are in sufficient abundance to feed some thousands of cascades, which roll down into the valley from every part of the lofty barrier that encircles it. The Behut or Jhelum, the Hydaspes of Alexander, is the chief river: it runs through the whole length of the valley with a remarkably smooth current from east to west, and receives numerous tributary streams from every quarter. The plains of Cashmere being abundantly supplied with moisture, yield rich crops of rice, which form the common food of the inhabitants. On the higher grounds, among the hills, all the European grains, namely, wheat, barley, and other species, arrive at maturity. In this elevated region are also found most of the plants, fruit and forest trees, and flowers, common to Europe, such as violets, roses, narcissuses, and other flowers, which grow wild and perfume the air; and of fruits, the apple, the pear, the plum, the apricot, and the nut, with abundance of grapes; and many kitchen herbs peculiar to cold countries. The seeds of the nelumbo growing in the lakes affords an article of food to the lower classes. A superior sort of saffron is also produced in some parts; and iron of excellent quality is found in the high lands.

Some of the mountains which surround Cashmere are of great elevation; and, ascending from the plains, we find various climates and the productions of distant regions concentrated within a short space. The lower ridges of these mountains, which are of a moderate height, are covered with trees and verdure, and afford excellent pasturage for cattle of various species, as well as for wild animals; while they are entirely unfrequented by the ferocious beasts, such as lions and tigers. Above these fertile and romantic regions, the increasing cold gradually stunts the vegetation; and the traveller reaches that highest range of mountains which tower above the clouds into the regions of perpetual snow. Among these mountains are interspersed many fruitful and well-watered valleys; and they afford shelter to a rude and bold class of inhabitants, who, in these deep recesses, bid defiance to conquering armies, and who have little intercourse with the inhabitants of the plains, their poverty offering as little inducement to the visits of merchants as of warriors.

Cashmere has been long famed for the manufacture of shawls, which are distributed all over northern and western Asia, and are exported in great quantities to Europe. These shawls owe their peculiar beauty and fine texture to the wool which is brought from Thibet, lying at a distance of a month's journey to the N.E. The wool forms the inner coat with which the goat is covered, and the breed is peculiar to Thibet; all attempts to introduce it into India or Persia having invariably failed. The wool, which is originally of a dark gray colour, is bleached in Cashmere by the help of a preparation of rice-flour. The process of manufacture is very slow; not more than one inch being added to the finest shawls in the course of a day. It is estimated that about 16,000 looms were at one time employed in this manufacture; but of late years the demand has declined, owing to the decay of the Persian and Ottoman empires, and the desolation and poverty of the eastern countries. When Cashmere was tributary to Afghanistan, a great portion of the public revenue was exacted in shawls. The yarn into which the wool is spun is dyed with various colours, and after being woven, the piece is once washed, and the border, in which is displayed a variety of figures and colours, is attached to the shawls in so dexterous a manner that it is hardly possible to discover the junction. The price varies in proportion to the quality. A species of writing-paper is also made in Cashmere, which is highly praised throughout the East, and was formerly a great article of traffic; as were also its lacquered ware, cutlery, and sugar. A wine resembling Madeira is manufactured, and a spirituous liquor is distilled from the grape. The internal intercourse of the country is chiefly maintained by means of the numerous streams which intersect it, and which are navigated in long and narrow boats moved by paddles.

The aborigines of Cashmere are a distinct nation of the Hindu stock, and differ in appearance, language, and manners from their Tartar neighbours. The men are remarkably stout, active, and industrious; while the females have been celebrated for their beauty and complexion, which approaches to the brunette. They have been on this account much sought after for wives by the Mogul nobility of Delhi. They are naturally a gay and lively people, excessively addicted to pleasure, and notorious for falsehood and cunning all over the East. They are eager in the pursuit of wealth, and are considered as much more acute and intriguing than the natives of Hindustan generally are. They are said to be addicted to literature and poetry, which is probably limited to a few popular songs. The country, although fertile, has but a scanty population, the total number of inhabitants not exceeding 200,000. Of this amount, a considerable proportion consists of Mohammedans, partly Soonies, and partly also of the sect of Ali. All Cashmere is reckoned holy land; and miraculous fountains abound in all parts. There are numerous temples dedicated to the various objects of Hindu superstition, as Siva, Vishnu, Brahma, &c.; though many of these monuments of Brahminical superstition have been destroyed by Mohammedan invaders. The country is subject to the dreadful evil of earthquakes; and, to guard against their effects, all the houses are built of wood, which is abundant. The author of the Ayeen Acbery dwells with rapture on the romantic beauty of the valley of Cashmere, which was said to be the favourite retreat of the Mogul emperors when they relaxed from the cares of government; and this description is so far confirmed by Bernier, who, in 1663, visited this country in the suite of Aurungzebe.

As far as the history of Cashmere can be collected from imperfect traditions, the people appear originally to have been Hindus. The period of its subjugation to its Mohammedan conquerors is uncertain. About the year 1012 Mahmoud of Ghizni invaded and plundered the country, but does not appear to have taken permanent possession of it. In the year 1323 it was invaded by an army of about 70,000 Tartars, whose commander established himself as sovereign of the country, and was soon after converted to Mohammedanism by a priest, who in return was made his prime minister. His descendants reigned in Cashmere till the year 1541, when it was conquered by Mirza Hyder, on the part of the Emperor Humayon, and was annexed by Acbar to his empire in 1588. It was ruled by the house of Timour for 160 years, after which it was betrayed by the Mogul governor, about 1754, to Ahmed Shah Duranny, and constituted a province of the Afghan sovereignty. In 1819 it was conquered by the Sikhs, from which time till the year 1845 it was ruled by a viceroy appointed by Runjeet Singh of the Punjaub. The wanton irruption of the Sikh army into British territory at the close of the last-mentioned year, gave rise to the first Punjaub war, upon the termination of which the hill country between the Beas and the Indus, including the valley of Cashmere, was ceded to the British as indemnification for its expenses. The greater part of the territory thus ceded, the British transferred to Gholab Singh, under the treaty of Umritsur in 1846, in consideration of the payment of £750,000. By the provisions of that treaty, Gholab Singh acknowledges the supremacy of the paramount power, which in return is bound to aid him in defending himself from external aggression.

Cashmere, the capital of the above province, is a large city, which extends 4 miles on each side of the river Jhelum, over which there are seven wooden bridges. It is of un-

equal breadth; but in some places it is nearly 2 miles wide. North of the city, on the summit of the Kohi Maran, a hill rising 250 feet above the bed of the Jhelum, is the citadel, and in the south-eastern quarter is the small fort of Shore Ghur, where the governor resides. The houses are mostly built of wood, with partition walls of brick and mortar. They are high, being many of them three stories, with sloping wooden roofs covered with a bed of fine earth, which in summer is sown with flowers, and exhibits a lively appearance. The town, like most of those in the East, is dirty in the extreme, its narrow streets being covered with the filth of the inhabitants, who, even in the East, are proverbially unclean. The river is, notwithstanding, covered with baths. The public buildings in the city are not remarkable; the most celebrated being the Jama Musjid, or Great Mosque, and the mosque of Shah Hamedan. There is a beautiful lake near the town, which extends from the N.E. quarter in an oval circumference of 5 or 6 miles, and communicates with the Jhelum by a narrow channel near the suburbs. On the east side of the lake is a detached hill called Tukhti Suliman, and on the west an eminence designated Huri Parbut. The verdant and level margin of this beautiful piece of water was the favourite resort of the Mogul emperors, and is still in many places overspread with the relics of their pleasure-grounds and palaces. Of these the most celebrated is the Shalimar, laid down by the Emperor Jehangir, and which has been selected by Moore for the closing scene of Lalla Rookh. The city of Cashmere is generally considered to have been founded by Pravarasena, who reigned from A.D. 128 to 176. Its elevation above the sea is about 5500 feet. Cashmere is also called Sirinagur. Lat. 34. 5., Long. 74. 58.

CASHY, a town and district in Northern Hindustan, tributary to the rajah of Nepaul, and situated between the 28th and 29th degrees of N. Lat., and about the 83d of E. Long. The country is mountainous, and little more is known of it than that it is one of the confederated states called the country of the twenty-four rajahs. The town is situated in E. Long. 82. 49. and N. Lat. 28. 42.

CASIRI, MICHAEL, a learned Maronite, was born at Tripoli in 1710. He studied at Rome, where he afterwards for ten years taught Arabic, Syriac, and Chaldee, and gave lectures in philosophy and theology. In 1748 he went to Spain, and was employed in the royal library at Madrid. He was successively named a member of the royal academy of history, interpreter of oriental languages to the king, and joint librarian of the Escurial, with a royal pension of 200 piastres. In 1763 he became principal librarian, a situation which he appears to have held till his death in 1791.

Casiri published a work entitled *Bibliotheca Arabico-Hispana Escurialensis*, 2 vols. fol., Madrid, 1760–1770. It is a catalogue of above 1800 Arabic MSS. contained in the library of which he was keeper. They are arranged under the heads of Grammar, Rhetoric, Poetry, Philology, and Miscellanies, Lexicons, Philosophy, Politics, Medicine, Natural History, Jurisprudence, Theology, Geography, and History. The last two classes, with a copious index, occupy the whole of the second volume. A full view of its contents, with some political comments, is given in the first appendix to Harris's *Philological Inquiries*, and in the second appendix to Barington's *Literary History of the Middle Ages*.

CASK, a vessel for holding liquors, sugar, &c. It consists of staves and headings, bound together by hoops. Casks are often made by machinery.

CASLON, WILLIAM, an eminent letter-founder, was born in 1692, in Hales Owen, Shropshire. When a boy, he served an apprenticeship to an engraver of ornaments on gun-barrels, and afterwards carried on this business on his own account in Vine Street, near the Minories. He also employed himself in making tools for bookbinders, and for the chasing of silver plate. While engaged in this business, the lettering of a book from tools cut by him attracted the attention of Mr Bowyer, who induced him to take the superintendence of a type-foundry, and lent him L.500 to begin the undertaking. In 1720 the Society for promoting Christian Knowledge engaged Mr Caslon to cut the fount for an edition of the New Testament and Psalter in Arabic. This undertaking he accomplished successfully; and in his subsequent productions he made so great improvement that the importation of type from Holland entirely ceased, and many of his founts were extensively used on the continent. He died in January 1766.

CASPE, a rich and populous city of Spain, in the province of Aragon, containing 8200 inhabitants. It is situated on the banks of the river Martin, which runs into the Ebro. Its prosperity has risen from the mines of iron and of coal which abound in its vicinity, and which have given rise to many manufactories; few, however, in proportion to the mineral wealth of the district and the requirements of the other provinces of Spain.

CASPIAN SEA, the Mare Hyrcanum of the ancients, derives its name from the Caspii, a tribe who settled on its shores. Among the Orientals it is known under a variety of names; by the Russians it is called the Sea of Astracan, and by the Turks Bahri-Ghong. It is situated between 36. 35. and 47. 25. N. Lat., and 46. 15. and 55. 10. E. Long., is the largest inland lake in the world, and has no outlet to the ocean. It is surrounded by the Russian governments of Astracan and Orenburg, the Caucasian countries, Persia, and Tartary; its greatest length is about 760 miles, and its greatest breadth about 400 from east to west; generally, however, only half that breadth, and where narrowest, not more than 120 miles across. Its estimated area is from 120,000 to 140,000 square miles.

The eastern coast of the Caspian Sea, with the exception of the projecting promontory of Tuk-karagan and a few gulfs, extends nearly in a direct line more than 10° in length from north to south, between the parallels of 37 and 47. The small gulf of Aster-âbâd forms its southern limit, whilst its northern boundary is marked by a very large bight at its N.E. extremity, which receives the waters of the Emba. The principal branch of this river expands, before it reaches the sea, into a great many shallow basins like lakes, the northern branch of it being nearly choked up with sand. All this part of the coast, as well as that adjoining to the N. and N.W., is extremely flat and shallow, as the large rivers, namely, the Aral, the Volga, and the Tuck, which here empty themselves into the sea, are constantly bringing along with them a quantity of sand which accumulates on the shores. The whole of the northern part of the Caspian Sea, which, like the adjoining eastern coast, is exceedingly low, is thus rendered so shallow, that for the distance of several miles from the shore the water is only a few feet in depth; and an immense number of small sand-hills and banks of sand, make it difficult to land on any part of it. Similar sand-hills occupy also the shore itself, and extend to a considerable distance inland among the steppes; but it cannot be said that they form a continuous ridge. At the very commencement of this Sinus Mortuus (Mertooi Kultuk) there rises a small chain of calcareous hills, called the Chink, which forms, as it were, the rampart of a remarkable high level, named Ustürt, which extends under the 45th parallel, between the Aral and Caspian Seas, with a breadth of about 160 miles. This high plain is so steep towards both those seas, that it rises above the Caspian 639 English feet; and its fall towards the side of the Aral is not less. The elevation of this plain is never less than 550 feet, and is in some places more than 727 feet above the level of the Caspian; it extends nearly in a direct line between the two seas; and it sinks so insensibly, that there is nowhere to be observed anything like a continuous chain

of hillocks, and it can only be considered in the light of one elevated plain. The extreme headlands of this high plain, namely, the Aksakál, the Sarak, the Kará-úl, and the Kará-tâu, form so many small connected hill-tops round the bight of Tuk-kará-sú, which is the southern branch of the Sinus Mortuus. This continuous range of hills incloses the whole coast from this spot to Alexander's Bay, and extends nearly straight from north to south, with the exception of a small divergence to the east. They consist throughout of a recent tertiary calcareous formation. The depth of this coast is very remarkable; it is seldom so little as 6 fathoms, generally between 10 and 18. This gulf, as in Alexander's Bay, is connected with a large bight, the entrance of which is formed by a precipitous rocky bank, from which the bight widens considerably, and receives several rivers descending from the high plateau, namely, the Sirbâsh, the Kichik and the Kumbenska. Further east, and a little to the south, where we come upon the gulf of Kenderlui, the land shelves off, but as it is entirely surrounded by hillocks, it seems to receive no stream. Here, however, the hills of Kenderlui form again small chains connected with the larger hilly chain of the Karakhteh; and further inland, they are quite lost in the elevated plateau. A coast stream, the Turakhth, here empties itself into the sea, between the Kenderlui and Karâ-hóghâ gulfs. The narrow entrance into this supposed very deep gulf is confined by a number of rocks, forming some dangerous eddies, and is surrounded in all directions by a steep bank; along the whole of its coast there is but one inconsiderable stream, the Makranda. To the east it is bounded by some small hilly knolls, which extend from north to south; but these are less remarkable for their height than for the great number of salt lakes, most of them very small, which are in the lower valleys. Finally, under N. Lat. 40. the gulf of Balkân is bounded by the extreme points of this elevated plateau; here also the hills rise steep and precipitous from the bank, and present at the top porphyritic formations, which in remote times have broken through beds of granite which occur also round the gulf of Krasnovedsk, at the entrance of the bay of Balkân, and in some of the islands in the bay. Here, likewise, this plateau consists of a tertiary calcareous formation which, towards the Balkân, crops out in single protuberances. The Búlân mountain, which shuts in to the east the bay of Balkân, so that the Amu-daryâ, whose old bed Dr Eichwald followed up for 5½ miles, could only fall into the bay between the great and little Balkân, whilst it wound round the southern point of the great Balkân and thus emptied itself into the bay in a direction from south to north. In consequence of the confined outlet of this old river, the bay is continually more and more choked up with sand, and has scarcely a depth of a few feet. Indeed, all this part of the coast is very much sanded up, and is very flat.

On the west shore the whole space between this sea and the Euxine is filled by the immense masses of the Caucasus. From this region the Caspian receives rivers which have their sources nearly 300 miles distant, the principal of which are the Rouma, the Terek, and the Kur; and it is remarkable, that between the Volga and the Terek, a distance of nearly 200 miles, there is only one river mouth, that of the Rouma, in consequence of the land at a little distance from the sea being so elevated as either to leave the running water to be absorbed in the soil, or to direct it towards the Don or the Euxine. The rivers that fall into the basin of the Euxine, Baltic, and Arctic ocean have their sources in this region at so small a distance from each other that a short canal has been cut uniting the Tvertza and Schlina, and connecting the Caspian with the Baltic through the Volga. Much of the timber used in the imperial yard at Petersburg is cut in the woods of Kazan and conveyed by this route up the Volga to its destination. This canal was the work of Peter the Great; and the same prince projected the union of the Caspian and Euxine Seas by connecting two small streams, affluents of the Volga and Don, which in the neighbourhood of Tzaritzen approach each other within two miles.

There are no tides in this sea, nor are there any regular currents; but the high winds which occasionally blow over its large surface cause considerable and irregular agitations in its motions.

The mean depth of the Caspian Sea is from 400 to 600 feet, and in some places is found to be 2700 feet; but its waters are everywhere very shallow near the shore, especially towards the west. Vessels drawing 9 or 10 feet water are thus compelled to unload far from the shore, excepting near Bakou and some other parts of the lake. Navigation is, in general, dangerous, owing to the frequency and violence of the east and west winds; and the contracted space forces the navigator to beat about in order to avoid the sand-banks concealed near its shores. The waters of the Caspian have a slightly bitter taste, communicated by the naphtha which abounds in the surrounding countries, and is carried into it by the streams which it receives; but they are not so salt as those of the ocean, in consequence of the great volume of water poured into it by the Volga and its other tributaries. Horses do not refuse to drink along the shores and near the mouths of the rivers.

Colonel Monteith says, "while in the habit of bathing in the Caspian, I found along the whole of the coast that for 100 yards the sea was not more than three feet deep, which increased like a step to 6, and at a short distance to 10, the intermediate space being perfectly level and the sand hard."

This sea is distinguished by a remarkable phenomenon. It appears to increase and decrease in actual bulk—in periods, according to native report, of about thirty years each. It is difficult to assign any cause for this phenomenon proportionate to the effect.

Monteith found the extra pressure of the atmosphere to be equivalent to a column of 390 feet in height; Burnes, some four or five years later, to one of 800 feet. It is therefore not improbable that the varying level depends in some degree on the varying pressure of the atmosphere. But whatever may be the variations in the surface of this lake, there can be little doubt that it was formerly much more extensive on three sides, north, west, and east, and it seems to be still diminishing. The fact that it never increases nearly in the ratio of the water poured into it, combined with its want of outlet to discharge that water, has led to the most extravagant hypotheses to account for a phenomenon apparently so paradoxical. But the diminution of the waters of this sea may be most reasonably accounted for by the evaporation, which is incredibly great in these regions; not from the temperature, which is lower than might be expected in these latitudes, but from the extreme dryness of the atmosphere. On the E. and N.W. shores the land rises in terraces like the present bed of the lake, and presents incontestible proofs of having been formerly covered with sea-water. The surface abounds in sea-salt, sea-weed, marshes, and salt-pits, together with innumerable shells exactly resembling those of the Caspian Sea, and which are not found in any of the rivers. Towards the east the whole country has the same appearance of a deserted sea-bed. Hence it is inferred that at no distant period the Black Sea, the Caspian, and the Aral formed one body of water. This conclusion is strengthened by the presence of the same species of fish, seals, &c., in the three seas.

It has always been evident that the bed of the Caspian was very low; and in the beginning of the present century Messrs Engleherdt and Parrot, with the view of ascertaining the fact, performed a series of barometric levellings between its shores and those of the Baltic, the result of which gave a depression of 333 feet for the surface of the

Caspian Sea.

Caspian. The accuracy of this measurement was however suspected by Humboldt and others: and to determine the question, the Russian government despatched an expedition, which after two years' labour, completed in 1838 a series of trigonometrical levellings, which were commenced on the 31st October 1836 by Messrs G. Fuss, Sadler, and Sawitsch, at the town of *Kagalnik*, a little to the south of Azov, at the mouth of the Kagalnika, which falls into the Sea of Azov, between Lat. 47. 4. 26·3. N., and Long. 2. 27. 59·5. E. from Paris. Thence they were continued by Stawropol (where the expedition passed the winter), Georgijewsk, Motdock, and Kisljar, to the town of Tschemoi Rynok, on the shore of the Caspian, a little to the north of the mouth of the Terek, where the operations were terminated. The whole extent of this line is about 800 versts (about 600 English miles).

The measurements were of two kinds—trigonometrical and barometrical: the results obtained from six different measurements varied from 73 feet 1 inch to 83 feet 3 inches. The discrepancies in these results arise from the way in which the observers have calculated the measurements for the purpose of removing the effect of terrestrial refraction. We cannot decide as to which of these results is most probably the correct one; but it is evident, that as the uncertainty amounts only to a few feet, we shall not be very far wrong in assuming, as the number most nearly approaching the truth, the mean of the last four (which are those that agree the best with one another), viz., 81·3 English feet. Even should this number not be regarded as a definitive result, yet, at all events, by means of this first trigonometrical survey of the Caucausian isthmus, the fact is established *that the surface of the Caspian Sea is actually at a lower level than that of the ocean*, an opinion which has been lately disputed; and it is likewise ascertained, *that the depression is only about one quarter so great as the older measurements led us to believe.*[1]

Considering the latitude, the temperature of this sea is extremely low. The northern part is frequently frozen, and the ice at the mouth of the Volga does not generally break up till April. The following table shows the temperature at Leukoran, on the west shore of the Caspian (in 38° 44′), Palermo, and Trèves.

Seasons.	Leukoran. 38° 44′.	Palermo. 38° 7′.	Trèves. 49° 46′.
Winter	38·16	52·5	36·1
Spring	55·9	59·0	50·
Summer	76·8	74·3	64·
Harvest	62·1	66·2	50·1
Mean	57·2	62·9	50·

The surrounding country abounds with forests of fine trees, many of them covered with vines and hops, which frequently extend over three and four trees: almost every kind of fruit grows wild in abundance, and this is perhaps the country from which the greater part were originally brought. The largest class of vessels that navigate the Caspian vary in burden from 90 to 100, and sometimes 150 tons burden. Small fisheries are established on most of the rivers, and salmon are taken in large quantities. This fish is found in great abundance in all the clear mountain streams, but never in those proceeding from the swamps. Herrings, although taken in considerable quantities in the Terek and Aras, are never found to the south of the last-mentioned river. The fishermen do not ply their vocation in the open sea, nor have they nets fit for the purpose. Steamboats have been introduced into the Caspian, and the trade of the sea is entirely in the hands of Russia. (Hanway's *Travels;* MacCulloch's *Geograph. Dict.; Edinburgh Philosophical Journal; Journal of the Royal Geograph. Society;* Humboldt's *Central Asia;* Pallas's *Travels;* Eichwald.)

Casque ‖ Cassano.

CASQUE, or CASK, a piece of defensive armour for the head and neck; otherwise called *head-piece* and *helmet.* The word is French, *casque*, from *cassicum* or *cassicus*, a diminutive of *cassis*, a helmet. Le Gendre observes, that anciently in France the gens d'armes all wore casques. The king wore a casque gilt, the dukes and counts silvered, gentlemen of extraction polished steel, and others plain iron. There were great varieties in its form and fashion. F. Joubert makes it the most ancient of all the coverings of the head, as well as the most universal.

CASSANA, NICOLO, called NICOLETTO, an eminent Italian painter, was born at Venice in 1659, and became a disciple of his father Giovanni Francesco Cassana, a Genoese, who had been taught the art of painting by Bernardino Strozzi. Having painted portraits of some of the English nobility, Nicoletto was invited to England and introduced to Queen Anne, who sat to him for her likeness, and conferred on him many marks of favour. He died in London in 1713.

CASSANDER, king of Macedon after Alexander the Great, was the son of Antipater. He made many conquests in Greece, abolished democracy at Athens, and intrusted the government of that state to the orator Demetrius. Olympias, the mother of Alexander, having slain Aridæus and his wife Eurydice, with many others, Cassander besieged Pydna, whither the queen had retired, took it by stratagem, and caused her to be put to death. He married Thessalonica, the half sister of Alexander the Great; and murdered Roxana and Alexander, the wife and son of that conqueror. Ultimately he formed an alliance with Seleucus, Ptolemy, and Lysimachus against Antigonus and Demetrius, over whom he obtained a decisive victory near Ipsus in Phrygia, B. C. 301. Cassander died of dropsy three years after, in the nineteenth year of his reign. See MACEDONIA.

CASSANDRA, in Grecian story, daughter of Priam and Hecuba, was beloved of Apollo, who promised to bestow on her the spirit of prophecy if she would comply with his desires. Cassandra accepted the proposal; but no sooner had she obtained that gift than she laughed at the tempter, and refused to fulfil her promise. Apollo revenged himself by ordaining that her predictions should be discredited; and hence she prophesied in vain the ruin of Troy. On the capture of that city she was ravished by Ajax the son of Oileus, in the temple of Minerva. In the distribution of the booty, Cassandra fell to the lot of Agamemnon, who loved her deeply; but in vain did she predict that he would be assassinated in his own country. Both perished through the intrigues of Clytemnestra, who was herself afterwards slain by Orestes, to avenge his father's death.

CASSANO, a town of Naples, in the province of Calabria Citra, 7 miles E.S.E. of Castrovillari. It stands in a concave recess of a steep mountain, round an isolated rock on which are the ruins of an ancient castle. It has hot sulphureous baths of great local reputation, and is surrounded by beautiful scenery. Pop. 4400, engaged in the manufacture of maccaroni, stamped leather, table-linens, and cotton and silk stuffs. Corn, fruits, timber, &c., are raised in the vicinity.

---

Alexis Sawitsch, entitled *Ueber die Höhe des Caspichen Meeres und der Hauptspitzen des Caucasichen Gebirges* (Dorpat, 1839), and partly from M. G. Sadler's dissertation, entitled *Beobachtungen über die irdische Strahlenbrechung und über die Gesetze der Veränderung derselben* (Dorpat, 1839).—EDIT.

CASSAVA, a species of starch obtained from the roots of *Jatropha manihot*, which is made into a kind of bread by the natives of Africa and the West Indies. It is the celebrated *manioc* of the negroes, and the *tapioca* of Brazil.

CASSEL, a walled town of Western Germany, capital of the electorate of Hesse-Cassel and of the province of Lower Hesse, stands on the river Fulda, 124 miles N.N.E. of Frankfort-on-the-Main, with which it has lately been connected by railway. N. Lat. 51. 19., E. Long. 9. 35. Pop. (1846) 32,516. The town is pleasantly situated on both sides of the Fulda, which here is navigable. The old town and upper new town, with the Wilhelmshöhe and Frankfort suburbs, lie on its left or western side; and the lower new town, with the Leipzig suburb, on the east bank. The streets of the old town, which lies low, are narrow, crooked, and dirty; but the upper or *French* new town (so called from having been laid out by French refugees) is one of the handsomest towns of Germany. The Elector's palace, an edifice nowise remarkable, stands in the *Friedrichsplatz*, the largest square in any German town, being 1000 feet in length, and 450 in breadth. In its centre there is a marble statue of the Elector Frederick II., by whom the town was much improved and embellished. Its finest street is *Königs-strasse*, 5100 feet in length, and 60 in breadth. The handsomest building in Cassel is the museum, which contains a library of 90,000 volumes, with collections of natural history, antiquities, coins, physical and mathematical instruments, &c. St Martin's church, a Gothic edifice, contains the burial-vault of the electoral family. The other chief buildings are the town-hall; the Bellevue palace; the unfinished palace of the Cattenburgh, now overgrown with weeds; the observatory; picture-gallery, with portraits by Rembrandt, Vandyk, Rubens, and others; the arsenal, barracks, mint, opera-house, electoral stables, and riding-school; besides several churches, schools, and hospitals. Cassel has numerous literary and scientific institutions. The manufactures, which are on a small scale, are almost exclusively confined to the wants of the state. The principal of these are, cotton, silk, and woollen goods, leather, earthenware, jewellery, chemicals, tobacco, &c. &c. During the brief reign of Jerome Bonaparte, Cassel was the capital of the kingdom of Westphalia. From the Wilhelmshöhe gate an avenue of lime-trees 3 miles in length leads to the summer palace of the elector, situated in the midst of beautiful gardens, adorned with statues and water-works, which have acquired for it the name of the German Versailles.

CASSEL, a town of France, department of Nord, stands on an isolated hill in the middle of an extensive plain, 28 miles N.W. of Lille. Though only 800 feet high, this hill, from the flatness of all the adjacent country, commands a most extensive view. Pop. 4000. Manufactures—lace, thread, hosiery, oil, soap, earthenware, &c.

CASSIA BARK, the bark of *Cinnamomum Cassia*, is one of our most common species, and is very generally sold in the shops under the name of common cinnamon. In European commerce this bark is known by the name of cassia lignea, and is imported into England from Singapore, Malabar, Mauritius, Bombay, Calcutta, Batavia, and Canton. The bark is imported into this country in bundles, which are from 18 to 24 inches in length, and weigh from $1\frac{1}{2}$ to 3 lb. The bundles consist of quills of bark from $\frac{1}{2}$ to 1 inch in diameter, generally single, rarely double. The bark is much thicker than that of true cinnamon, and the taste is more pungent and less sweet, though somewhat similar to that of cinnamon. The properties of cassia bark depend on the presence of a volatile oil—the oil of cassia, which is imported in a pretty pure state as an article of commerce from Singapore. The comparative cheapness of this agreeable aromatic causes it to be largely used instead of cinnamon. In the year ending 5th January 1852, there were imported into Britain 267,462 lb. of cassia lignea; in 1853, 496,833 lbs.; and in 1854, 220,733 lbs. The oil of cassia is largely sold to the cook and confectioner under the name of oil of cinnamon.

CASSIA BUDS come to us from Singapore, and are probably the flower-buds of the same tree which yields the cassia bark, though this is not precisely known. They possess the same pungency of taste as the cassia bark, and may be substituted for it. The duties on cassia lignea from British possessions from 9th July 1842 have been $\frac{1}{20}$d. per lb., and on that from foreign countries $3\frac{3}{20}$d. per lb. Cassia buds pay no duty.

CASSIANUS, otherwise called JOANNES EREMITA, and JOANNES MASSILIENSIS, a celebrated solitary, and one of the first founders of monastic institutions in western Europe, was probably born about A.D. 360, and is supposed to have died about the year 448. The place of his nativity has been much disputed; but he spent the early part of his life in the monastery of Bethlehem, with his friend Germanus. In company with that monk he visited Egypt, and dwelt for several years among the ascetics of the desert near the banks of the Nile. In 403 he repaired to Constantinople, where he received ordination as deacon from the hands of Chrysostom. Cassianus was afterwards at Rome; and proceeding thence to Marseilles, he there founded two religious societies—a convent for nuns, and the abbey of St Victor, which last is said to have numbered, during his time, 5000 inmates. He was eventually canonized; and a festival in honour of St John Cassian long continued to be celebrated at Marseilles on the 25th of July.

Cassianus left *Collations*, or conferences of the fathers of the desert; *Institutions*, in twelve books; and seven books upon the *Incarnation*. Of these works, which are all written in Latin, various editions have appeared. The most complete and best edition of his collected works is that published at Frankfort, 1722, folio, and reprinted at Leipzig, 1733, folio. Cassianus is reckoned among the first of the Semi-Pelagians; a sect that was condemned by some synods, and rejected by the church. (See *De Joanne Cassiano Massiliensi*, &c., Rostochii, 1824, 1825, 4to, by G. F. Wiggers.)

CASSIMIRE, or CASHMIRE. See CASHMERE.

CASSINI, JOHANNES DOMINICUS, an excellent astronomer, born at Piedmont in 1635; died at Paris in 1712 For the history of his observations and discoveries, see article ASTRONOMY, pp. 802–3.

CASSINI, *James*, the only son of the former, was born at Paris in 1677, and died in that city in 1756. See article ASTRONOMY, pp. 805–6.

CASSINI, *de Thury*, *Cæsar François*, was the second son of James Cassini, and was born in 1714, at Paris, where he died in 1784. See article ASTRONOMY, pp. 805–6.

CASSIODORUS, MAGNUS AURELIUS, secretary of state to Theodoric the Great, was born at Scylacium (Squillace), of an ancient and wealthy Roman family, about A.D. 468. His genius and great attainments were conspicuous at a very early age, and were fully appreciated by Theodoric; under whom and his successors Cassiodorus was successively appointed to the highest offices of state. Having continued for a long series of years to conduct the government of the Ostrogothic kingdom with singular ability and success, at the age of seventy he retired to the monastery of Viviers, in his native province of Bruttium (Calabria); and in this retreat, of which he had been the founder, he devoted the remaining thirty years of his life to study, and the composition of treatises on history, metaphysics, the seven liberal arts, and divinity. He was assiduous also to elevate the standard of education among the ecclesiastics, and particularly encouraged them to make transcripts of ancient works. In his leisure hours, too, he exercised his mechanical ingenuity in the construction of a variety of philosophical toys, such as sun-dials, water-clocks, and perpetual lamps. The writ-

ings of Cassiodorus evince great erudition; but his Latin style partakes much of the corruptions of the age. The best edition of his collected works is that of Father Garet, in 2 vols. folio, published at Rouen in 1679, and reprinted at Venice in 1729. Of these works the most valuable is his *Variarum Epistolarum, libri* xii., a series of state papers drawn up by the command of Theodoric and his successors.

CASSIOPEIA, or CASSIOPE, in fabulous story, was the wife of Cepheus king of Æthiopia, and the mother of Andromeda, whose beauty (or as others say, her own) she extolled above that of the Nereids. At their instigation, Neptune chastised the presumption of Cassiopeia by inundating the country, and sending a sea monster to ravage the land. In order to appease the god, Andromeda was chained to a rock to be devoured by the monster; but she was rescued by Perseus. (See PERSEUS.) Cassiopeia, after death, was placed among the stars; and hence the constellation of that name. (Ov. *Met.* v.; Hyg. *Fab.* 64; Arat. *Phæn.* 187.)

CASSIOPEIA, in *Astronomy*, a constellation in the northern hemisphere, situated near to Cepheus. In 1572 there appeared a new star in this constellation, which in magnitude and brightness surpassed even Jupiter; but it diminished by degrees, and it had at the end of eighteen months disappeared. Several astronomers of that age, as Tycho Brahe, Kepler, Maurolycus, Lycetus, and Gramineus, wrote dissertations on it. Beza the landgrave of Hesse, Rosa, and others wrote to prove it a comet, affirming that it was the same which had appeared to the Magi at the birth of our Saviour, and that it came to declare his second coming. On this subject they were answered by Tycho.

CASSIS, in antiquity, a plated or metallic helmet, different from the *galea*, which was of leather.

CASSIS, a small seaport-town of France, department of Bouches-du-Rhône, stands in a narrow valley on the Mediterranean, 10 miles S.E. of Marseilles. Its harbour is small; but it has some building yards, and a considerable trade in fruits and muscatel wine. The Abbé Barthélémy was born here in 1716. Pop. 2000.

CASSIUS, LONGINUS, or L. CASS. LONGINUS RAVILLA, was tribune of the people in B.C. 137, when he proposed the vote by ballot, which was strenuously resisted by the patricians. In B.C. 127 he was made consul; and two years afterwards censor. Though equitable as a judge, he was so inflexible that his tribunal was called the "Rock of the Impeached." From the judicial severity of this Cassius, very severe judges have been called *Cassiani*.

CASSIUS, *Spurius* (whose full name was *Sp. Cassius Viscellinus*), a renowned Roman general and consul, and the proposer of the first agrarian law; in consequence of which he was accused of aspiring to regal power and condemned to death as a traitor, B.C. 485. He thrice enjoyed the consular dignity, was general of the horse under the first dictator created at Rome, and twice received the honour of a triumph. See ROMAN HISTORY.

CASSIUS, *C. Longinus*, a celebrated Roman jurist, and governor of Syria, A.D. 50, wrote ten books on the civil law, and commentaries on Vitellius and Urseius Ferox, which are quoted in the Digest.

CASSIUS, *Caius*, or *C. Cass. Longinus*, one of the murderers of Julius Cæsar. After his defeat by Antony at the battle of Philippi, he ordered his freedman to put him to death with his own sword, B.C. 42. See ROMAN HISTORY.

CASSIUS, *Powder of* (so named from the inventor), is a beautiful purple colour used in the arts, especially in the staining of glass and porcelain-painting. It is a precipitate obtained by adding solution of protochloride or sesquichloride of tin to solution of gold.

CASSOCK (French *casaque*, a cloak), a kind of robe or gown, worn over the other garments, particularly by the clergy. The modern cassock is a close garment which clergymen wear under their gowns.

CASSOON. See ARCHITECTURE, p. 508.

CASSOWARY. See ORNITHOLOGY.

CAST, a figure or small statue of bronze, plaster, &c.

CASTAGNO, ANDREA DEL, an early painter of the Florentine school, who died about 1477. He imitated Massaccio in boldness of attitude, but was deficient in grace and colouring. His name is rendered infamous by his base assassination of his friend Domenico Veneziano, from whom he had obtained the Flemish secret of *oil-painting*.

CASTALIUS FONS, or *Castalia*, a celebrated fountain at the foot of Mount Parnassus, sacred to Apollo and the Muses, who were thence called *Castalides*. According to some, it was named after the nymph Castalia, who threw herself into the fountain when pursued by Apollo. Its murmurs were deemed prophetic.

CASTANEA, the genus to which the sweet chestnut, *C. vulgaris* vel *vesca*, belongs. See BOTANY.

CASTANET (Spanish *castaneta*, or rather *castañuela*, probably from *castaña*, a chestnut), an instrument much used by the Spaniards and Moors as an accompaniment to their dances and guitars. It is composed of two small pieces of ebony, or other well-dried hardwood, shaped like spoons, which are placed together with the concavities inwards, fastened by a string to the thumb, and beat with the middle finger, so as to produce a rattling sound. This instrument is very similar to the ancient *crotalum*, which appears to have consisted, in its original form, of two pieces of reed, which made a clattering noise when shaken with the hand.

Definition.

CASTE. By this term is here meant the classification and distribution of the members of a community into certain classes or orders, for the performance of certain functions, with the enjoyment of certain privileges, or the endurance of certain burthens; and the establishment of hereditary permanence in these orders, the son being ordained to perform the functions, to enjoy the privileges, or sustain the burthens, of the father, and to marry only in his own tribe, without mixture of classes, in regular succession, throughout all ages.

Origin of the term.

The term *Caste* is borrowed from the Portuguese. It was the term applied by that people, who first of the European nations formed establishments in India, to the classes which they found established upon this principle among the inhabitants of that portion of the globe; and from them, as it was owing to their intercourse that the rest of the nations of modern Europe first derived their familiarity with the manners and institutions of the people of India, the term made its way, and became established in the other languages of Europe.

The institution itself appears to have been very extensively introduced even in the early ages of society.

This institution widely diffused.

In regard to the ancient Egyptians, the fact is universally and familiarly known. The President de Goguet, who, with singular industry, and no ordinary judgment and sagacity, explored the remains of ancient times, comprises a great body of history in a few words. "We may farther observe," says he, "that, in the Assyrian empire, the people were distributed into a number of tribes, and that professions were hereditary, that is to say, children were not permitted to quit their father's occupation and embrace another. We know not the time nor the author of this institution, which from the highest antiquity prevailed over almost all Asia, as well as in several other countries." It is not necessary here to surcharge the reader with the authorities which he quotes. The passage itself (p. i. b. i. ch. i. art. 3) will be consulted by all who distrust the legitimacy of his inference, or desire to prosecute the inquiry.

It is stated in the common histories of Greece that Cecrops distributed into four hereditary classes or tribes all

the inhabitants of Attica. And we are informed by Plutarch, in his Life of Theseus, that by this prince the class of priests, and that of nobles, in other words, the magistrates or military leaders, were united into one, and therefore the society was composed of three classes: 1, The sacerdotal, legislating, and ruling class; 2, the class of husbandmen; and, 3, the class of tradesmen. "To the nobility," says the illustrious biographer, "he committed the choice of magistrates, the teaching and dispensing of the laws, and the interpretation of all holy and religious things; the whole city, as to all other matters, being as it were reduced to an exact equality; the nobles excelling the rest in honour, the husbandmen in profit, and the artificers in number. And Theseus was the first who, as Aristotle says, out of an inclination to popular government, parted with the regal power; which Homer also appears to attest in his catalogue of the ships, where he gives the name of PEOPLE to the Athenians alone." There is a passage near the beginning of Plato's *Timæus*, which, though in a work of fancy, is not without some weight, as evidence either of conclusions which were drawn by men of research, or of traditions which were current among the people. In this passage not only is it asserted, that in the primeval state of the inhabitants of Attica they resembled the Egyptians in their division into hereditary classes and professions, but a very accurate description is given of those classes, five in number, viz. 1, The class of priests; 2, The class of handicrafts; 3, The class of shepherds and hunters; 4, The class of ploughmen; 5, The military class. Πρωτον μεν το των ἱερεων γενος, απο των αλλων χωρις αφορισμενον· μετα δε τουτο το των δημιουργων, ὁτι καθ' ἁυτο ἑκαστον, αλλῳ δε ουκ επιμεμιγμενον, δημιουργει· το τε των νομεων και των θηρευτων· το τε των γεωργων· και δη το μαχιμον γενος, απο παντων των γενων κεχωρισμενον, ὁις ουδεν αλλο πλην τα περι τον πολεμον ὑπο του νομου προσεταχθη μελειν.

We are informed by Aristotle, that the people of Crete were divided into castes, after the manner of the Egyptians, by the laws of Minos. Εοικε δε ου νυν ουδε νεωστι τουτ' ειναι γνωριμον τοις περι πολιτειας φιλοσοφουσιν, ὁτι δει διηρησθαι χωρις κατα γενη την πολιν, και το τε μαχιμον ἑτερον ειναι, και το γεωργουν· εν Αιγυπτῳ τε γαρ εχει τον τροπον τουτον ετι και νυν· τα τε περι την Κρητην. Τα μεν ουν περι Αιγυπτον, Σεσωστριος, ὡς φασι, ὁυτω νομοθετησαντος· Μινω δε τα περι Κρητην. *Polit.* vii. 1.

It is worthy of observation that certain vestiges at least of that ancient institution are still visible in Egypt. "La distinction par familles," says General Reynier (*De l'Egypte*, p. 56), "se retrouve encore dans les villes: l'éxercise des arts et metiers est hereditaire: le fils imite les procedés de son père, et ne les perfectionne pas."

We have a remarkable passage to prove that among the ancient Persians the same division into castes existed which still obtains among the Hindus. In the *Zendavesta*, as translated by M. Anquetil Duperron, it is said,—"Ormusd declared, there are three measures (literally weights, that is, tests or rules) of conduct, four states, and five places of dignity. The states are, that of the priest; that of the soldier; that of the husbandman, the source of riches; and that of the artizan or labourer." "We are told," says Sir John Malcolm (*Hist. of Persia*, i. 205), "that Jemsheed divided his subjects into four classes, and that he allotted to each a separate and fixed station in life, which seems to imply that the condition of the ancient Persians was like that of the modern Hindus; and that the extraordinary institution of cast which now exists in India was once known in Persia." Sir John proceeds to state some reasons which induce him to doubt the reality of the fact; in not one of which, however, is there a particle of weight.

Sir John quotes and translates for us a passage from Strabo, which asserts that a similar institution existed in Iberia. "Four kinds or classes of people inhabited that country. From what they consider the first class, they appoint their kings, according to nearness of kindred and seniority; these administer justice, and head their armies. The second is of priests, who take charge of their political rights with respect to their neighbours; the third of soldiers and husbandmen; the fourth of the people in general, who are slaves of the king, and perform every menial office." This account of the distinctions of the castes is evidently incorrect, and by a man who was not well informed. The fact of the Iberians being distributed in a remarkable and uncommon manner he knew, otherwise there would have been no occasion to single out the fact in the description of this particular people. He knew also that they were divided into four principal classes. With regard to the matters of detail, however, his words bear internal evidence that either his information had been vague and inaccurate, or that his recollection had become so.

From a dissertation of Mr Joinville on the religion and manners of the people of Ceylon (*Asiatic Researches*, vii. 430), we find that there is sufficient evidence to prove the existence of a similar institution anciently among the Buddhists of Ceylon, and by consequence to infer it among the other Buddhists spread over so large a portion of Asia.

After this evidence of the general diffusion of the institution of castes in the rude ages of the world, especially in Asia, there is a temptation, from the following passage of Herodotus (lib. i. cap. 101), to infer its existence among the Medes at the commencement of the monarchy. Εστι δε Μηδων τοσαδε γενεα, Βουσαι, Παρητακηνοι, Αδιζαντοι Βουδιοι, Μαγοι. There is nothing in the passage which serves to fix the meaning of the word γενεα; and the names, it is plain, are words of the ancient Median language. But we know that the Μαγοι were the priests; and hence there is reason to conclude that the other words also are names of classes and professions; in other words, of hereditary castes.

The institution of castes may be traced in places with which we are more intimately connected. Mr Millar, to whom the world is indebted for almost the first lessons which it received, in tracing the facts of history up to the general laws of the human mind, has called our attention to the fact, that in the ancient condition of our Saxon ancestors they were divided into four classes: 1, The artificers and tradesmen; 2, the husbandmen; 3, those who exercised the honourable profession of arms; and, 4, the clergy. Mr Millar adds (*Historical View of the English Government*, b. i. ch. ii.), "From the natural course of things, it should seem, that in every country where religion has had so much influence as to introduce a great body of ecclesiastics, the people, upon the first advances made in agriculture and in manufactures, are usually distributed into the same number of classes or orders. This distribution is accordingly to be found, not only in all the European nations formed upon the ruins of the Roman empire, but in other ages and in very distant parts of the globe. The ancient inhabitants of Egypt are said to have been divided into the clergy, the military people, the husbandmen, and the artificers. The establishment of the four great *castes*, in the country of Indostan, is precisely of the same nature."

Human nature is very uniform in the phenomena which it exhibits. The new world displays a striking resemblance to the old. The same stage of society presents nearly the same results. There is reason to conclude that something which resembled the institution of castes existed among the ancient inhabitants of Peru and Mexico. The Count Carli, the celebrated author of the *Lettres Americaines*, when treating (Lett. xiii. and xiv.) of the

laws of the Peruvians, says, "Les citoyens furent distribués en classes ou tribus.——Il n'étoit pas permis, ni par mariage, ni par changement d'habitation, de confondre une classe avec l'autre; car la loi defendoit de se marier dans une autre famille que celle d'où l'on sortoit.—— N'oublions pas le soin qu'on avoit de l'éducation des enfans. C'étoit toujours le père qui élevoit son fils. L'éducation consistoit à apprendre aux enfans rôturiers le metier que chaque père de famille exerçoit," &c. We are informed by Clavigero (*Hist. of Mexico*, b. iv. § 5), that "the sons in general learned the trades of their fathers, and embraced their professions; thus they perpetuated the arts in families, to the advantage of the state."

Such is the extent to which this institution has existed on the surface of the globe. We shall next endeavour to ascertain the state and condition of the human mind, to which it may be considered as owing its origin.

Origin and causes of the diffusion of this institution.

The lowest and rudest state in which the human race are found to exist, may, in a certain general way, be described as the hunter state. That of the shepherd is the next stage in the progress toward the advantages of civilized life. The agricultural state succeeds; when men begin to cultivate the ground for the means of subsistence, and experience the benefit of fixed habitations. As long as they continue in the condition of hunters or of shepherds, the division of labour is unknown, and all the multitude of blessings which it brings. Every family is itself the author of all the simple accommodations which it knows. The tent or hovel, the waggon or cart, is constructed by the men; the coarse garment is spun and even woven by the women. In this situation of things, the accommodations with which it is possible for human beings to supply themselves are few and imperfect, and life is a scene of privation.

When population has so far multiplied as to render the produce of flocks and herds insufficient for the means of subsistence, and the cultivation of the land has become necessary, the inconveniences arising from the want of the division of labour become still more sensible and oppressive. The labours of the field are neglected while the family are engaged at the loom or in repelling the incursions of an enemy. The accommodations of lodging, of clothing, of taste, and fancy, are wretchedly supplied, when the business of extracting the means of subsistence from the soil requires the greater part of their time and attention.

The progress, however, of human improvement, though not necessarily, is commonly, in point of fact, at least in the more uncultivated ages, exceedingly slow. Men continue to suffer under the inconveniences which their present condition imposes upon them, complaining of their miseries, but unable to form a clear conception of the means of exemption, and doubtful of all the remedies which are pointed out to their attention. In the mean time, as the human mind is essentially progressive, and, unless in very extraordinary circumstances, never fails to make progression, the uneasiness which is felt under the inconveniences of a state to which the mind has become superior, and above which it is rising higher and higher every day, is continually increasing, and at last rises to such a height that some change is unavoidable; and the society are prepared to welcome the most plausible of the schemes which are proposed to them.

The grand steps which are made in improving the condition of mankind, though essentially the result of a progression in the minds of the society taken as a whole, are commonly the immediate suggestion of some one individual, or small number of individuals, whose conception of the necessity of a change, and of the means of relief, is more clear and determinate than that of the rest of the community.

In the earliest stages, when the human mind is weak, and prone to superstition, the individuals who project the great improvements in the state of society endeavour to accelerate the consent of the people, and overcome their reluctance to innovation, by giving to their projects the character of a divine revelation and command. The first legislators of almost every country we find to have represented themselves as depositaries of the divine will, and intrusted with a revelation from heaven.

If we take the Hindus as a model, the people divided into castes with whom our acquaintance is the most complete, we shall conclude that some individual, wise enough to perceive the cause of the inconveniences under which men suffer while the division of labour is unknown, and placed in circumstances which enabled him to clothe himself with a divine authority, overcame in most places the reluctance of the people to so great a change of their manners and habits, and accelerated the date of their improvement, by persuading them that the divine power or divine powers now commanded them to be divided into classes for the performance of certain offices.

In the early stages of society, however, the wants of men are few; and the ideas of the legislator himself are incapable of extending to a great variety of cases. In such periods the power of superstition is always exceedingly great. Unacquainted with the laws of nature, and exposed to the most dreadful vicissitudes, which they are altogether unable to foresee, human life appears to men in that situation to hang altogether upon invisible powers. The human mind is incessantly occupied with conjectures respecting what those unknown powers will produce, and with tormenting apprehensions that they will produce evil rather than good. The persons who, in this state of things, are skilful enough to create a persuasion that they are better acquainted than others with the will of these powers, more especially if accompanied with a persuasion that they have an influence over that will, and can turn it more or less whichever way they please, become an object of supreme regard. Nothing can be done without them. They are the most important class in the community. When society is first divided into classes for the sake of the division of labour, the priests, therefore, are always a separate class, and always in the place of highest distinction.

After the evils to which men in the rude state of society conceive themselves liable from the unknown and invisible authors of physical events, the evils to which they are liable from the incursions of hostile men appear the next in magnitude. While the institutions of society are imperfect, and the human mind is weak, these evils are very great, and present a terrific picture to an imagination perpetually haunted with fear; and, in the same circumstances, the advantages derivable from hostile incursions upon others appear the greatest. In the rude ages of society, therefore, the soldier is always a character of great importance. He is the barrier against those evils which rank next in order after the evils against which the priest affords relief. When classes are first formed, the military are, therefore, always a separate class, and next in rank and veneration to the class of the priests. It is remarkable that the rank and consequence of both classes are chiefly founded upon fear. It is also remarkable, though a natural consequence, that, in all ages, they are most apt to be venerated by the most timid persons, the most timid sex, for example, over whose imagination the priest and the soldier have a proverbial sway. It is further observable, and a necessary consequence, that since the fears with respect to invisible powers, and with respect to the incursions of hostile men, gradually decline as society advances, and have less and less effect upon the imaginations even of those who are most apt to be governed by

the passion of fear, the respect for the castes of priest and soldier are destined to sink in relative importance as the institutions of society are improved, and the human mind becomes strong.

After provision is made, in that early stage of society which we are endeavouring to describe, against the two classes of fears to which the priest and the soldier oppose their respective shields, the care of subsistence is the object of greatest importance. A class of husbandmen, therefore, is a necessary and never-failing institution; and, in the scale of rank and consequence, this order follows immediately after the sacerdotal and the military castes.

Besides the means of subsistence, other accommodations are required. But at first very few are so much as known, and, by consequence, very few are demanded. One class of the community are, therefore, supposed to be sufficient for the supply of all other wants, and the performance of all other services.

It is obvious, that reflection upon the laws of human nature would lead us to draw a picture nearly the same with this, if we were called upon to describe the state of society at the time when the division of labour is first introduced, even if we had no specific facts to direct our inquiries. In a remarkable passage in Plato, in his second book *De Republica*, he ascribes the origin of political association and laws to the benefits which are sought for by the division of labour. *Γιγνεται πολις, ὡς εγ᾽ ὠμαι. επειδαν, τυγχανει ἡμων ἑκαστος, ουκ αυταρχης, αλλα πολλων ενδεης.* As men cannot be supplied with accommodations in any tolerable degree but by the division of labour and employments, one man producing one thing, another producing another, and every man getting what he wants, by exchange with other men, an association of a certain number of men is necessary for the common well-being; and hence society and laws. In exact coincidence with the deduction which we have presented above, he says that the simplest form of a society would consist of four or five orders of men. *Αλλα μεν πρωτη γε και μεγιστη των χρειων ἡ της τροφης παρασκευη, δευτερα δε οικησεως, τριτη εσθητος και των τοιουτων* . . . . . . *Ειη δ᾽ αν ἡ γε αναγκαιοτατη πολις εκ τετταρων η πεντε ανδρων.* The coincidence is very nearly complete between the speculation and the practice; between what is in this manner inferred, and what is recorded of ancient nations, and witnessed among the Hindus.

Amidst all the difficulties under which, especially in rude ages, human society and the human mind make progress, small are the steps which can be taken at once. When professions were separated, and the vast benefits derived from the separation began to be felt, the human mind was not sufficiently strong to perceive that there was no danger whatsoever that they should ever again be combined and confounded. No; it was imagined to be another grand effort of the same wisdom which had made the separation, to take care of its permanence, and to make provision for securing the benefits of it throughout all ages. With this view it was thought necessary to ordain and sanction, by divine authority, that the son should follow the profession of the father, and be subject to the severest punishment if he engaged in any other occupation. To secure also, in each profession, the due succession of sons to fathers, it was necessary that marriage should be strictly regulated; and the method which obviously enough suggested itself for that purpose was, that the members of each class, male and female, should be compelled, under the severest penalties, to marry only among themselves, and never, by intermarriage, to ruin and confound the separate castes.

So far the aim, at any rate, was good. The benefit of the whole society was the object which all these regulations were accounted useful to promote; and no degradation of any of the classes was either intended by any of these enactments, or necessary for the ends which they were destined to serve.

The degradation of one set of the castes, in comparison of another, was the result of an after-thought, and in the pursuit of ends of a different description. When one of the castes, as that of the priests, or the soldiers, found itself possessed of an influence over the minds of the rest of the community, such that it could establish certain points of belief in its own favour, it was never long before it availed itself of that advantage, and pushed it to the utmost. If it could inspire the belief that it was more noble, and worthy of higher privileges and greater honour, than the rest of the community, it never failed to get this point established as an incontrovertible right, not the result of the mere will of the community, but of an absolute law of nature, or even a revelation and command from God.

As every elevation of one class implies a correspondent degradation of another, and as there is no end to the elevation which one class will aim at, there is no end to the degradation which will be imposed upon another, if the state of the human mind is sufficiently weak to give to one class an unbounded influence over the belief of another. How naturally this extreme degradation is grafted upon the institution of castes, will immediately appear.

Of the Indian castes in particular.

As we derive our most minute and practical acquaintance with the shape into which society is moulded by the establishment of castes, from our intercourse with the Hindus, the particulars which are at this day exhibited in Hindustan, and provided for by their laws, afford the most certain means of acquiring precise and specific ideas concerning this remarkable institution.

According to the sacred law book, entitled the *Ordinances of Menu*, the Creator, "that the human race might be multiplied, caused the Brahmin, the Cshatriya, the Vaisya, and the Sudra (so named from *scripture, protection, wealth*, and *labour*), to proceed from his mouth, his arm, his thigh, and his foot." "For the sake of preserving this universe, the Being, supremely glorious, allotted separate duties to those who sprung respectively from his mouth, his arm, his thigh, and his foot. To Brahmins he assigned the duties of reading the Veda, of teaching it, of sacrificing, of assisting others to sacrifice, of giving alms if they be rich, and, if indigent, of receiving gifts; to defend the people, to give alms, to sacrifice, to read the Veda, to shun the allurements of sensual gratification, are, in a few words, the duties of a Cshatriya; to keep herds of cattle, to bestow largesses, to sacrifice, to read the Scripture, to carry on trade, to lend at interest, and to cultivate land, are prescribed or permitted to a Vaisya. One principal duty the Supreme Ruler assigns to a Sudra, namely, to serve the before-mentioned classes, without depreciating their worth." Such is the employment of the castes, and such the authority whence it is derived.

The next great peculiarity is, the degree of elevation which one set of the castes was enabled to usurp, and the correspondent degradation of the others.

Priests.

1. The Brahmins, or the priests. "Since the Brahmin sprung from the most excellent part," says the same divine code immediately quoted, "since he was the first born, and since he possesses the Veda, he is by right the chief of this whole creation. Him the Being who exists of himself produced in the beginning, from his own mouth, that having performed holy rites, he might present clarified butter to the gods, and cakes of rice to the progenitors of mankind, for the preservation of this world. What created being, then, can surpass him, with whose mouth the gods of the firmament continually feast on clarified butter, and the manes of ancestors on hallowed cakes? Of created things, the most excellent are those which are ani-

mated; of the animated, those which subsist by intelligence; of the intelligent, mankind; and of men, the sacerdotal class. When a Brahmin springs to light he is born above the world, the chief of all creatures. Whatever exists in the universe, is all in effect the wealth of the Brahmin; since the Brahmin is entitled to it all by his primogeniture and eminence of birth."

As the Brahmin exclusively, or at least to a supreme degree, engrosses the regard and favour of the deity, so he is entitled to the respect and veneration of mortals. Kings themselves, and the most exalted of men, are infinitely inferior to the meanest of the Brahmins. "Let the king," we again quote the ordinances of Menu, "having risen at early dawn, respectfully attend to Brahmins learned in the three Vedas, &c.... and by their decision let him abide. Constantly must he show respect to Brahmins who have grown old, who know the Scriptures, who are pure." "The king must appoint seven or eight ministers, &c..... To one learned Brahmin, distinguished among them all, let the king impart his momentous counsel. To him, with full confidence, let him intrust all his transactions; and with him, having taken his final resolution, let him begin all his measures." "Let him not, although in the greatest distress, provoke Brahmins to anger, by whom Brahma, the all-devouring fire, was created, the sea with waters not drinkable, and the moon with its wane and increase. What prince would gain wealth by oppressing those who, if angry, could frame other worlds, and agents of worlds,—could give being to new gods and mortals? What men desirous of life would injure those by the aid of whom worlds and gods perpetually subsist,—those who are rich in the knowledge of the Veda? A Brahmin, whether learned or ignorant, is a powerful divinity, even as fire is a powerful divinity, whether consecrated or popular. Thus, though Brahmins employ themselves in all sorts of mean occupations, they must invariably be honoured; for they are something transcendently divine."

The least disrespect shown to one of the sacred order is the most atrocious of crimes. "For contumelious language to a Brahmin," says the code of Menu, "a Sudra must have an iron style, ten fingers long, thrust red-hot into his mouth; and for offering to give instruction to priests, hot oil must be poured into his mouth and ears."

The laws give to the Brahmins the most remarkable advantages over the other classes of the community. Neither the person, nor so much as the property of the Brahmin, can ever be touched, in awarding punishment for the most atrocious crimes. "Never shall the king," says one of the ordinances of Menu, "slay a Brahmin, though convicted of all possible crimes; let him banish the offender from his realm, but with all his property secure, and his body unhurt." This privileged order was entirely exempt from taxes. One of the most important of all duties is to bestow wealth upon the Brahmins, by incessant gifts and donations. See article Brahmin.

Military caste.

2. The Cshatriyas, or the military caste. Though the Brahmins look down upon this class, they are looked up to by all the rest of the classes with a veneration inferior only to that with which the Brahmins are regarded. The difference of rank in India is not a mere ceremonial distinction. The advantages which are conferred by it, or the injuries endured, are immense, and to the suffering party unspeakably degrading. Any infringement, even of the external marks of the abjectness of the degraded party, is punished as a heinous crime. "If a man of an inferior caste," says Halhed's *Gentoo Code*, "proudly affecting an equality with a person of superior caste, should speak at the same time with him, the magistrate in that case shall punish him to the extent of his abilities." It is unnecessary, under this head, to enter into details, which would occupy a disproportionate space.

Agricultural caste.

3. The Vaisyas, the agricultural and commercial class. It is still less necessary to multiply particulars under this head. When the two extremes are sufficiently explained, what modifications of respect or disrespect belong to the intermediate stages may be easily inferred.

Servile caste.

4. As much as the Brahmin is an object of intense veneration, so much is the Sudra an object of contempt, and even of abhorrence, to the other classes of his countrymen. The business of the Sudras is servile labour, and their degradation inhuman. The most abject and grovelling submission is imposed upon them as a religious duty, and enforced by the most dreadful punishments. They are so completely deprived of an equal share in the advantages of the social union, that few of those advantages are reserved to them. The classes above them are restrained from injuring them, even in the case of the greatest crimes, by punishments far slighter than those which are appointed for injuries done to the superior classes. The crimes which they commit are punished with much heavier inflictions than equal crimes committed by individuals of the classes above them. Neither their persons nor their labour is free. "A man of the servile caste," says the sacred ordinance of Menu, "whether bought or unbought, a Brahmin may compel to perform servile duty; because such a man was created by the Self-existent for the purpose of serving Brahmins."

According to the principles of the same code, the Sudra was excluded from the benefits of property. "No collection of wealth must be made by a Sudra, even though he has power, since a servile man who has amassed riches gives pain even to Brahmins." "A Brahmin may seize without hesitation the goods of his Sudra slave; for as that slave can have no property, his master may take his goods."

The degradation of the wretched Sudra extends not only to every thing in this life, but even to religion, and the prospect of future happiness. "Let not a Brahmin," says the above code, "give advice, nor what remains from his table, nor clarified butter of which part has been offered, nor let him give spiritual counsel to such a man, nor inform him of the legal expiation for his sin; surely he who declares the law to a servile man, and he who instructs him in the mode of expiating sin, sinks with that very man into the hell named Asamvrita." Not only are the Sudras not allowed to read any of the sacred books; but, "if," says the *Gentoo Code*, "a man of the Sooder reads the Beids of the Shaster, or the Pooran, to a Brahman, a Chehteree, or a Bice" (Halhed's mode of spelling the names of the four castes), "then the magistrate shall heat some bitter oil, and pour it into the aforesaid Sooder's mouth; and if a Sooder listens to the Beids of the Shaster, then the oil, heated as before, shall be poured into his ears, and arzeez and wax shall be melted together, and the orifice of his ears shall be stopped up therewith. If a Sooder gets by heart the Beids of the Shaster, the magistrate shall put him to death. If a Sooder gives much and frequent molestation to a Brahman, the magistrate shall put him to death." From this specimen of particulars a judgment may be formed with regard to the rest.

Inconveniences of this institution as society advances.

Though this is the primary and original formation of castes, the institution, unless where it happens to be early broken up, does not rest here. The distribution of the members of the community into four classes only, and the appropriation of their services to four species of employment, though a great step in improvement at the time they were instituted, must have become productive of many inconveniences as the wants of society multiplied. The bare necessaries of life, with a few of the rudest accommodations, are all the means of gratification which it af-

fords, or is capable of affording, to mankind. As the desires of mankind, however, speedily extend beyond such narrow limits, a struggle must have early ensued between the first principles of human nature and those of the political establishment.

And this was not the only evil to which, under this primary institution, society was exposed. The different castes were strictly commanded to marry with those exclusively of their own class and profession; and the mixture of the classes by the union of the sexes was guarded against by the most sanguinary laws. This, however, was a result which laws were not sufficiently powerful to prevent. Irregularities occurred, and children were born who belonged to no caste, and for whom there was no occupation. A more calamitous event could not fall upon human society. Unholy and infamous, on account of that violation of the sacred law to which they owed their unwelcome birth, these wretched outcasts had no resource for subsistence except two; either the bounty of the regular classes, to whom they were objects of contempt and abhorrence, not of sympathy; or the plunder of those classes by whom they were oppressed—a resource to which they would naturally betake themselves with all the ingenuity of necessitous, and all the ferocity of injured men.

When a class of this description became numerous, they must have filled society with the greatest disorders. The nature of the case would have drawn the philosophical mind to this conclusion had no testimony existed. It so happens, however, that this is one of the few facts in the ancient history of the Hindus which can be ascertained from their record. In the preface to that compilation of the *Hindu Laws* which was translated by Mr Halhed, it is stated that, after a succession of good kings, who secured obedience to the laws, and under whom the people enjoyed felicity, came a monarch, evil and corrupt, under whom the laws were violated, the mixture of the classes was perpetrated, and a new and impious race were produced. The Brahmins put this wicked king to death, and, by an effect of miraculous power, created a successor, endowed with the most excellent qualities. Nevertheless the kingdom did not prosper, by reason of the Burren Sunker (so were the impure and irregular brood denominated); and it required all the wisdom of this sage and virtuous king to devise a remedy. He resolved to form a classification of the mixed race, and to assign them occupations. This accordingly was the commencement of arts and manufactures. The Burren Sunker became all manner of artizans and handicrafts. Of the classes into which they were distributed, one was appointed to the weaving of cloth, another to works in iron, and so in all other cases, till the subdivisions of the race were exhausted, and the wants of the community were provided for. Among the Hindus thirty-six castes of the impure race are enumerated, all inferior in rank and privileges even to the Sudra. To proceed farther in the detail would be inconvenient and useless. By this supplement to the institution of the four primary castes, two great evils were remedied at once; the increasing wants of an improving society were supplied, and a class of men, who had been the pest of the community, were converted to its service.

How nearly the actual state of things among the Hindus did ever correspond with the written accounts of the institution of castes, we do not know. But even at the time when Europeans first became acquainted with them, many points of the separation were disregarded; and this has been in constant progress; so that at present the principal interruptions to the business of life, occasioned by the niceties of caste, are removed; and the distinctions are felt on certain limited occasions only.

The only remaining inquiry with respect to the institution of castes, which seems appropriate to this article, is that of its utility or inutility as a part of the social establishment. And a few words will, we think, suffice to convey clear and determinate ideas upon this subject.

General view of the effects of this institution.

It is the distinction of man's nature, that he is a progressive being. It is by this grand characteristic that he is separated so widely from the inferior animals. When found in circumstances and situations in which the benefits of progression seem not to have been reaped, he is raised but a slight degree above the condition of some of the more perfect of the inferior animals. His peculiarity is, that he is susceptible of progression, and, unless when he is placed in circumstances which impose extraordinary restraints upon the principles of his nature, does invariably and incessantly make progress. Even when he originates in a state little above that of the inferior animals, he rises, and gradually ascends from one stage to another, till his elevation above all the other inhabitants of this globe is immense; nor is there any limit which our knowledge permits us to set to his final attainments and felicity. In whatever state the other animals originate, in that state they remain throughout all ages, and seem altogether incapable of improvement.

In regard to man, therefore, considered as a class of beings or an order of existence, every thing is to be considered as beneficently important in proportion as it favours his progression; every thing is to be considered as mischievously important in proportion as it obstructs and impedes that progression. And it is by this grand test of all that is good and evil in human institutions that we shall endeavour to estimate the effects of the establishment of castes.

We shall not here adduce the elevation of one set of the classes, and the correspondent degradation of another, obviously the cause of infinite evil; because it may be with justice maintained, that this horrid elevation, and equally horrid depression, are not essential parts of the institution of caste, but arise from other causes, and may, in fact, be separated from that institution.

First of all, it is evident, that at the time when the number of castes and professions is established, unless it could be foreseen what are all the species of operations or arts by which the desires of man, in all their possible varieties, are capable of being gratified, and what are all the possible divisions of labour from which any good can arise, the appointment of fixed, unalterable castes and professions must oppose an insuperable barrier to human advancement in these two grand instruments of progression, the division of labour and the practice of new arts, as invention may suggest them, or the multiplying desires of an improving society may create the demand. Since it is obviously impossible that all these things can be foreseen, it is abundantly certain that the institution of any fixed number of arts and trades is exactly an institution for preventing the progression of mankind. This deduction appears to be conclusive, and, if there were no other argument, affords a complete answer to the question respecting the utility of castes.

Even in the trades and arts which are known and provided for at the time of the institution, it is by no means certain that this fixed order of the persons who are to practise them is a contrivance well adapted for carrying these arts themselves, whether large in number or small, to their highest state of perfection. It by no means follows that a man will do any thing better than any other man, because his father did it before him. To establish a caste for any particular art or profession, is giving a sort of monopoly to that particular description of men. It is a wide monopoly, to be sure; but, as far as the

appropriation of the art to one class is calculated to have any effects, they must so far be such as it is of the nature of a monopoly to produce, and hence unfavourable to the progress of the art. The way which presents itself to the reasoning mind, as that which is best calculated for improving every branch of human industry or skill, is to open, as widely as possible, the doors to competition; not to exclude any man, of whatever origin, who may appear to have an extraordinary genius for any particular thing, but to allow him, through competition, to reap the reward of his superiority, and hence to feel all the motives that can prompt him to excel. The acquirements of one generation are not transmitted to another more surely when they are transmitted from father to son, than when they are transmitted in the way of promiscuous instruction. Nor does it necessarily, or even commonly, happen, that the learner gets more careful instruction from his father, than he would from a man who is not his father; or that he himself is more intent in his application, and careful to learn, because it is his father who instructs him.

In the sciences and the fine arts, the power of excelling in which depends upon rare combinations of circumstances, to limit the number of competitors, and shut up the field from all but the members of a particular tribe, is obviously a powerful expedient for diminishing the chance of progression. In regard to literature and knowledge the case is clear and decisive. To confine the prosecution of it to a particular tribe. is to insure a perpetuity of ignorance and misery to the human race. It will be decidedly the interest of the knowing class to maintain as much ignorance as possible among the rest of the community, that they may be able the more easily to turn and wind them conformably to their own purposes; and, for that end, to study, not real knowledge, nor the means of making mankind wiser and happier, but the means of deluding and imposing upon them the arts of imposture. With this clear and incontrovertible inference, how exactly does the historical fact correspond? How truly and faithfully have the Brahmins acted up to that rule? They have made it a law revealed from heaven to keep the great bulk of the community in ignorance. And what branch of knowledge have they ever studied but the science of delusion? There is first their theology; a mass of absurd fictions, to chain the imagination of ignorant and foolish men. And then there is astrology, which concludes the circle of all their studies, and may be justly styled the second part of the act of imposture; even their mathematics, in which they made some little progress, being studied in no other shape than as a part of the business of astrology.

Another circumstance appears to merit no slight regard. The institution of castes is calculated to multiply the evils, so dreadful in magnitude, which are apt to arise from the principles of population, and is opposed to the measures which are calculated to lessen or prevent them. The evils which are apt to be produced by an occasional superabundance of people in any one of the departments of industry and subsistence, are exceedingly diminished when the greatest possible facility is given to the supernumerary individuals, of distributing themselves through all the other departments of industry and subsistence. And these evils, it is obvious, are all raised to the greatest height when the possibility of that distribution is taken away; and individuals, in whatsoever degree superabundant, are still confined to their own department. As this is a topic, the elucidation of which it is easy to carry on, we shall content ourselves with the bare hint which has thus been given, and leave the development to the reflections of the reader.

It may be added, as a supplement to what was said about the obstruction which, by the institution of castes, is given to progression, not only in the division of labour and the multiplication of arts, but even in perfecting the arts which are known and practised, that the strict confinement of one tribe of men to one tribe of operations must have a strong tendency to create a habit of routine, and hence an aversion to all innovation; a disposition to acquiesce in what has constantly been done, and hence to deaden that activity of mind which is on the alert to catch at every chance of improvement,—that admirable temper, on which the greatest rapidity in the march of human amelioration essentially depends.

It was intended, after thus presenting the reasons on which we conclude that the institution of castes is an arrangement altogether opposite to the interests of human nature, to have stated and answered the reasons which have been advanced by Dr Robertson, in the appendix to his *Historical Disquisition concerning India*, and more recently by the Abbé Dubois in his *Description of the Character, &c. of the People of India*, to prove that the institution of castes is really beneficial. But after looking over these reasonings with a view to that answer, they have appeared to us to be so weak and insignificant as to be altogether unworthy the trouble of transcription. A sufficient answer to every point which they adduce will be found in the considerations which we have already urged upon the subject; and we doubt not that we may safely intrust the decision to the judgment of the reader. (J. M—L.)

CASTEL, Louis Bertrand, a learned mathematician, was born at Montpellier in 1688, and entered the order of the Jesuits in 1703. At first he was a student of literature, but afterwards devoted himself entirely to mathematics and natural philosophy. He wrote a *Traité de la Pésanteur Universelle*, Paris, 1724; *Mathématique Universelle; Le plan du Mathématique abregé*, and other works. But the work which attracted most attention at the time was his *Optique des Couleurs*, or treatise on the melody of colours, a subject which he endeavoured to illustrate by a *Clavelin Oculaire*, or ocular harpsichord. The treatise and the illustration were, however, quickly forgotten. He also published a critical account of the system of Sir Isaac Newton in French. Castel died in 1757.

CASTEL-A-MARE, or Castellamare, a city and seaport on the gulf of Naples, 17 miles S.E. of the city of that name. It is pleasantly situated on the lower slopes of a hill, and along a sheltered beach, commanding an extensive view of the Bay of Naples from Vesuvius to Misenum. It stands near the site of the ancient *Stabiæ*, destroyed by Sulla in the social war, but which continued to exist as a small place till A.D. 79, when it was overwhelmed along with Pompeii and Herculaneum by the great eruption of Vesuvius. It was here that the elder Pliny met his death on that occasion. The city takes its name from the castle which was erected by Frederick II., surrounded by walls and towers in the thirteenth century by Charles I. of Anjou, and strengthened by additional fortifications by Alfonso I. of Aragon. It is the seat of a bishopric, and has a royal palace, cathedral, several churches and convents, military hospital, barracks, handsome quay, royal arsenal, and dockyard, where the large ships of the Neapolitan navy are built. There are manufactures of linen, silk and cotton goods, and leather. The port is small, and divided by two forts. The hill immediately above the town is covered with villas and casini; among which is the royal Casino of Quisisana, more remarkable for its fine prospect than for its magnificence as a palace. The town is connected by railway with Naples. Pop. 18,000.

Castel-a-Mare, a seaport-town of Sicily, on the gulf of the same name, in the province of Trapani. It is a small dirty town, but has a considerable export trade in wine, fruit, grain, &c. Pop. 6000.

CASTEL GRANDOLFO, a small village of Italy, standing on an eminence above the N.W. margin of Lake Albano, 14 miles from Rome, and chiefly remarkable for its palace, the summer residence of the pope. Pop. 1200.

CASTEL-NAUDARY, a town of France, capital of an arrondissement of the same name, in the department of Aude, 21 miles west by north of Carcassonne. It is pleasantly situated on an elevation near the Canal du Midi; but is very indifferently built, having few public buildings worthy of notice except the church of St Michael, said to be the finest in the department. There are manufactures of woollen and cotton goods, leather, earthenware, and a considerable trade. It was founded by the Visigoths on the site of the ancient *Sostomagus*, and took the name of *Castrum Novum Arianorum*—of which the present is a corruption. It suffered severely in the crusade against the Albigenses; but is chiefly noted in history for the battle fought there in 1632 between the forces of Louis XIII. and of Gaston Duc d'Orleans, in which the Duc de Montmorency was wounded and made prisoner, and soon after conveyed thence to Toulouse and executed. Pop. (1851) 9712.

CASTEL SARRASIN, a town of France, capital of an arrondissement of the same name, in the department of Tarn et Garonne, pleasantly situated on the Songuine, near its influx into the Garonne, 12 miles west of Montauban. The walls which formerly surrounded the town have been converted into promenades. It has manufactures of serges and other woollen stuffs, hats, leather, &c., and some trade in corn grown in the vicinity. Pop. (1851) 6950.

CASTEL VETRANO, a town of Sicily, near the S.E. extremity of the island, 12 miles east of Mazzara. It is well and regularly built, and has a population of about 14,000. Near it are the ruins of the ancient city Selinus, which was destroyed by the Carthaginians, B.C. 409.

CASTELL, DR EDMUND (1606–1685), a learned English divine and orientalist. He was educated at Cambridge, where he became master of Catharine Hall and Arabic professor; and was afterwards appointed canon of Canterbury. He had a large share in the publication of the London Polyglott, and wrote the *Lexicon Heptaglotton* or dictionary of seven languages. On this latter work, which occupied a great part of his life, he expended no less than L.12,000. When printed, the copies remained unsold, and were afterwards destroyed by vermin so as to be utterly unsaleable. He obtained several ecclesiastical preferments; and at the time of his death was rector of Higham Gobyon, in Bedfordshire. He bequeathed his oriental MSS. to the university of Cambridge, on condition that his name should be written on every copy.

CASTELLAN, a governor or constable of a castle. Also the name of a dignity or function in Poland. The castellans were senators of the lower class, who in diets sat on low seats behind the palatines. They were a kind of lieutenants of provinces, and commanded a part of the palatinate under the palatine.

CASTELLATION, the act of fortifying a house and rendering it a castle; which by the ancient English laws required the king's license.

CASTELLI, BERNARDO (1557–1629), a Genoese portrait and historical painter, was the intimate friend of Tasso, and took upon himself the task of designing and etching the figures of the *Gierusalemme Liberata*.

Valerio Castelli, son of the preceding (1625-1659), surpassed his father, and particularly excelled in painting battle-scenes. He painted the *Rape of the Sabines* for the ducal palace at Florence, and decorated the cupola of the church of the Annunciation at Genoa. In these works he is regarded as combining the fire of Tintoretto with the fine taste of Paolo Veronese.

CASTELLI, *Giovanni Battista* (1500-1570), an eminent Italian historical painter, was employed to decorate the Nunziata di Portoria in Genoa, the saloon of the Lanzi Palace at Gorlago, and the Pardo Palace of Charles V. of Spain. His best known works are the *Martyrdom of St Sebastion*, and the picture of our *Saviour as Judge of the world.*

CASTELLIO, SEBASTIAN, was born about the year 1515. Chatillon, Dauphiny, and Savoy, are mentioned by different authors as the place of his birth. He early gained the esteem of Calvin, who lodged him in his own house at Strasburg, and procured him a regent's place in the college of Geneva. In this office Castellio continued till 1544, when he was forced to quit it on account of his peculiar opinions concerning Solomon's Song and Christ's descent into hell. He retired to Basle, where he was made Greek professor; and died in great poverty in 1564. He incurred the displeasure of Calvin and Beza by differing from them in his doctrines concerning predestination and the punishment of heretics. His works are numerous. In 1545 he printed at Basle four books of dialogues, containing the principal histories of the Bible, in elegant Latin; but his principal work is a Latin and French translation of the Scripture.

The Latin translation he began at Geneva in 1542, and finished at Basle in 1550. It was printed at Basle in 1551, and dedicated to Edward VI. king of England. The French version was dedicated to Henry II. of France, and printed at Basle in 1555. The translation is greatly disfigured by the affectation of using only classical terms. Besides these Castellio wrote a Latin translation of the Sibylline verses, a Greek poem on John the Baptist, a translation of several treatises of Bernardo Ochino, and notes on the Epistle to the Romans.

CASTELLON DE LA PLANA, a town of Valencia, Spain, about 4 miles from the sea, and 40 miles N.N.E. of Valencia. N. Lat. 39. 57; W. Long. 0. 4. It derives its name from an extensive plain in which it is situated, and which is watered artificially by an aqueduct brought for the most part through solid rock from the Mijares, a stream about 5 miles distant. It is walled, and contains several excellent churches, in which there are paintings by Ribalta a native artist. The climate is mild and salubrious, and the soil fertile. There are no manufactures of any consequence, but it possesses a brisk local trade. Pop. estimated at 16,000.

CASTELLORUM OPERATIO, castle-work, or service and labour done by tenants for the building and upholding of castles. This was one of the three necessary charges to which all lands among the Anglo-Saxons were subjected.

CASTELO BRANCO, a town of Portugal, in the province of Beira, on a hill near the Liria, 64 miles east by south of Coimbra. It is surrounded by walls flanked by towers, and has a ruined castle on the summit of the hill. Pop. about 6000.

CASTELO DE VIDE, a walled town of Portugal, in the province of Alemtejo, 10 miles north of Portalegre. Pop. 5000.

CASTELVETRO, LUDOVICO (1505–1571), was a native of Modena, and the author of a *Commentary on Aristotle's Poetics*. At the instance of his rival Annibale Caro, he was cited before the inquisition to answer for a certain book of Melancthon which he had translated into Italian. Being afraid of the issue of his trial he fled to Basle, where he spent the rest of his days.

CASTI, GIAMBATTISTA, an Italian poet, born of humble parents in 1721, at Montefiascone, in the States of the Church. There, too, he commenced his studies, in which he made such progress that he was appointed in early youth professor of Greek and Latin in an academy of that town. He soon, however, quitted this obscure situation, and repaired to Rome, where his learning, acuteness, and agreeable disposition, recommended him to the notice and friendship of many eminent individuals. He was admitted a member of the academy *Degli Arcadi;* and might easily have risen from a canonship in the cathedral of Montefiascone, which he had already obtained, to much higher pre-

ferment in the church, had such been his ambition. But his love of freedom and restless disposition interfered with his ecclesiastical advancement. He gladly accepted the invitation of Prince Rosenberg (tutor to the Grand Duke Leopold) to accompany him to Vienna, where he was presented to the Emperor Joseph. He then visited most of the capitals of Europe, from Petersburg to Lisbon, and from Constantinople to Stockholm. On his return to Vienna he was appointed *Poeta Cesario* or poet-laureate, in the room of Metastasio; a situation which he held till some time after the death of the Emperor Leopold, when he resigned it, and retired to Florence in 1796. After two years' residence in that city, during which period he composed a great number of his works, he took up his residence at Paris; and though now far advanced in life, neither his habitual gaiety nor his ardour of literary composition were in any degree abated. Scarcely a day passed that he did not add something to his principal poem *Gli Animali Parlanti*, or write one of his poetical novels. At the same time he was the delight of society from the liveliness of his conversation, which was rendered yet more entertaining by his knowledge of the world. Though in 1803 he had passed the age of eighty-two, his strength both of mind and body afforded the promise of a yet longer life; but he died during that year, from a severe cold caught in returning home at a late hour. His funeral was attended by a great concourse of persons distinguished by literary eminence; and an eloquent funeral oration was pronounced on the occasion by Corona, an Italian physician.

The chief work of Casti is *Gli Animali Parlanti, Poema Epico, Diviso in XXVI. Canti.* In 1792 and 1793 the French revolution had attracted the attention and speculations of all Europe; and in this work Casti resolved to exhibit, under an allegorical veil, what he conceived to be the predominant feelings of the multitude, their avowed hopes, and secret designs. With this view, as he himself has expressed it, "he contrived a grand apologue, in which, through the medium of animals as speakers and actors, a complete political story might be exhibited, exposing the defects and absurdities of various political systems."

This work, which raised Casti to a very high rank among the modern poets of his country, was begun at Vienna in 1794. His situation, however, as poet-laureate, was unfavourable to the freedom of political satire, and this obstacle may have been one inducement to his resignation of that office. The poem was continued at Florence without interruption, and completed at Paris, where it was published in 1802, in 3 vols. 8vo; an impression which has been followed by various editions in Italy. It was translated into French, Spanish, and German, and there is also a free and abridged English version, executed with considerable spirit. To most of the Italian editions four apologues have been added; but these have no relation to the subject of the *Animali Parlanti.*

Casti now directed his attention to the composition and publication of poetical novels. As far back as 1778 he had written eighteen of these *Novelle Galanti;* but his poetical avocations at the imperial court had interrupted his progress; and meanwhile those which he had composed were surreptitiously printed, both in Italy and France, in a manner so inaccurate and disfigured, that they could scarcely be recognised by the author. Some, too, as *La Bella Circassa*, and *La Figlia che non ha giudizio*, which were not his, were added to the collection.

Under these circumstances, the injured poet resolved to collect his whole works in an edition to be printed under his own superintendence. He was prevented, however, by his sudden death; but his novels, which at the period of his decease amounted to forty-eight, were published by one of his Parisian friends, in 3 vols. 8vo, 1804, accompanied by a prefatory memoir of the author. The practice of tale-writing, which commenced with the author of the *Cento Novelle Antiche*, and was brought to such perfection by Boccaccio, had prevailed in Italy for nearly five hundred years before the age of Casti. The Italian novelists invariably copied from each other, as well as from those inexhaustible stores of fiction, the *Fabliaux* of the Trouveurs. The merit of Casti does not consist in the invention of his stories; his novels are founded either on mythological stories, or on preceding Italian tales. To the first class belong *Aurora, L'Origine di Roma, Diana ed Endimione, Prometeo e Pandora.* Almost all the rest are poetical versions from Boccaccio, Massuccio di Salerno, and other Italian novelists. The longest, *La Papessa*, is founded on the old story of Pope Joan. These tales are much admired by the Italians for purity of language and harmony of versification, and they contain many ingenious and sarcastic reflections on the hypocrisy, errors, and vices of men in every age and condition of life. They are disfigured, however, by an unpardonable licentiousness. Some of them also terminate rather flatly; and the *ottava rima* in which they are all written, and which has a certain degree of heaviness, even in the hands of Ariosto and Berni, is ill adapted to the gaiety and levity of the lightest of all species of composition. One cannot mention the tales of Casti without being naturally led to compare them with those of Fontaine, which are founded on similar originals, and written in something of the same spirit. But, if there be more asperity and caustic raillery in Casti, he is infinitely inferior to the French poet in ease, naïveté, and grace.

Casti is also author of the *Poema Tartaro*, a satiric poem, in twelve cantos, on the court of Catherine II. The scene of action, however, is laid in Asia, and all the names are fictitious. The first sketch of this mock heroic poem was made by the author during his visit to St Petersburg, in the train of Count Kaunitz, the Austrian ambassador. On his return to Vienna, Casti new-modelled the composition, struck out whatever might be likely to prove offensive to crowned heads in general, and inserted a complimentary episode on the celebrated journey of his imperial patron into the Crimea.

In the capacity of poet-laureate, it was his duty to provide new dramatic entertainments at stated periods; and Casti, whose genius was diametrically opposite to that of his celebrated predecessor Metastasio, conscious that he could not vie with him in the serious opera, applied himself to the *Opera Buffa*, in which he obtained great success. His *La Grota di Trofonio* is intended to ridicule the pretensions of false philosophers. The *Il Re Teodoro in Venezia*, suggested by an episode in Voltaire's *Candide*, was assigned to him by the emperor himself, who is said to have been much entertained with the lines

Senza soldi e senza regno
Brutta cosa è l'esser Re.

A third burlesque opera, of which Cicero is the principal character, is founded on the plot of Catiline. Although neither the novel nor the apologue was by any means a new species of composition among the Italians, yet Casti may be regarded as an original author, in so far as he has bestowed a new form on the first, and has given to the second an extent which it had not yet received, as well as directed it to an object to which it had not previously been applied. (J. C. D.)

CASTIGATION (Latin, *castigatio*, from *castus*, chaste), punishment, discipline, emendation, restraint. Among the Romans it denoted a military punishment inflicted on offenders by beating with a wand or switch, commonly of vine.

CASTIGATORY, an engine of correction formerly used to punish arrant scolds. It was called the *trebucket castigatory* or *cucking stool*, which in Saxon signifies *scolding stool;* afterwards corrupted into *ducking stool*, because the offender was plunged in water.

CASTIGLIONE, the name of numerous towns and villages of Italy, the principal of which is the Castiglione della Stiviere, in the Austrian delegation of Mantua, 22 miles N.W. of the town of that name. It is chiefly noted for the victory gained here by the French over the Austrian forces 5th August 1796. It has several churches, a ruined castle, and about 5000 inhabitants.

Castiglione, *Baldassare*, an eminent Italian nobleman, was born at Casalico in the duchy of Mantua, in 1478. He studied painting, sculpture, and architecture, and excelled so much in these arts that Raphael and Michael Angelo never thought their works complete without the approbation of Count Castiglione. He first distinguished himself in military service under the Duke of Milan, and was afterwards employed in a diplomatic capacity at the courts of Pope Julius II., Louis XII. of France, and Henry VII. of England. On his return he began his celebrated work entitled the *Corteglano*, which he completed at Rome in 1516. This work is full of moral and political instruction, and is written in a style of classic elegance and purity. A version of this work, together with the original Italian, was published at London in 1727, by A. P. Castiglione, a relative of the author. Count Castiglione was sent by Clement VII. as delegate to the court of the emperor Charles V., and died at Toledo in 1529. His death was probably hastened by an accusation which had been raised against him after the sack of Rome of having neglected the interests of his country.

Castiglione, *Giovanni Benedetto*, a celebrated painter, was born at Genoa, and studied for some time under Vandyk. He painted portraits, historical pieces, and landscapes; but is said chiefly to have excelled in fairs, markets, and rural scenes. His paintings are to be found at Rome, Venice, Naples, and Florence. He also executed a great number of etchings, which are spirited, free, and full of taste. His son, Francesco, excelled in the same subjects; and it is thought that many paintings which are ascribed to Benedetto are only copies after him, or perhaps originals by his son.

CASTILE (in Spanish *Castilla*), an ancient kingdom occupying the central districts of the Spanish peninsula. The history of Castile as a separate kingdom will be found under Spain. The northern part of the kingdom which was first rescued from the dominion of the Moors is called *Castilla la Vieja*, or Old Castile; the southern, which was a more recent acquisition, is called *Castilla la Nueva*, or New Castile. They are separated from each other by a lofty chain of sierras which pass under different local names, and stretching in a south-westerly direction from Aragon to Estremadura form the great watershed between the valleys of the Tagus and the Douro. The name of both provinces seems to have been derived from the existence of numerous forts (*castillas*) erected on the frontiers of the recovered territory to protect them from the reprisals of the enemy.

Old Castile was bounded north by the Bay of Biscay and province of Vizcaya; east by Navarre and Aragon; west by Leon and Asturias; and south by New Castile. It is now divided into the provinces of Burgos, Logroño, Santander, Soria, Segovia, and Avila. These are described under their respective heads. Area, 30,800 square miles. Pop. (1849) 1,037,477.

New Castile was bounded north by Old Castile and Aragon; east by Aragon and Valencia; south by Murcia and Andalusia; and west by Estremadura. It is now divided into the provinces of Madrid, Toledo, Guadalajara, Cuenca and Ciudad Real (La Mancha). These are described under their respective heads. Area 17,720 square miles. Pop. (1849) 1,490,800.

CASTILLON, a town of France, in the department of Gironde, on the right bank of the Dordogne, 10 miles east by south of Libourne. Here in 1451 a battle was fought between the English and French, in which the latter were victorious; and near this is the chateau of Montaigne, where that celebrated essayist died in 1592.

CASTING, the running of liquid metal into a mould prepared for that purpose. See Foundery.

Casting *in Sand or Earth*, is the running of metals between two frames or moulds filled with sand or earth, in which the figure that the metal is to take has been impressed *en creux*, by means of the pattern.

Casting, among sculptors, implies the taking of casts and impressions of figures, busts, medals, leaves, or the like.

The method of taking casts of figures and busts is most generally by the use of plaster of Paris, that is, alabaster calcined by a gentle heat. The advantage of using this substance in preference to others is, that notwithstanding a slight calcination reduces it to a pulverized state, it becomes again a tenacious and cohering body by being moistened with water, and afterwards suffered to dry. By this means either a concave or a convex figure may be given by a proper mould or model to it when wet, and retained by the hardness it acquires when dry; and, from these qualities, it is fitted for the double purpose of making casts, and moulds for forming casts. The particular manner of making casts depends on the form of the subject to be taken. Where there are no projecting parts it is very simple and easy; as likewise where there are such as form only a right or any greater angle with the principal surface of the body; but where parts project in lesser angles, or form a curve inclined towards the principal surface of the body, the work is more difficult.

The first step to be taken is the forming of the mould. For this purpose, if the original or model be a bas-relief, or any other piece of a flat form, it must be placed (its surface being previously well greased) on a proper table, and surrounded by a frame, the sides of which must be at such a distance from it as will allow a proper thickness for the sides of the mould. As much plaster as will be sufficient to cover and rise to such a thickness as to give the necessary strength to the mould, as also to fill the hollow between the frame and the model, must be moistened with water, till it be just of such consistence as will allow it to be poured upon the model. This must be done as soon as possible; otherwise the plaster will concrete or set, so as to become more troublesome in the working, or unfit to be used. The whole must then be suffered to remain in this condition till the plaster has become hard; and then, the frame being taken away, the preparatory cast or mould thus formed may be taken off from the subject entire.

Where the model or original subject is of a round or erect form, a different method must be pursued, and the mould must be divided into several pieces; or if the subject consists of detached and projecting parts, it is frequently most expedient to cast such parts separately, and afterwards to join them together.

Where the original subject or mould forms a round or spheroid, or any part of such round or spheroid, more than one half the plaster must be used without any frame to keep it round the model, and must be tempered with water to such a consistence that it may be wrought with the hand like very soft paste; but though it must not be so fluid as when prepared for flat-figured models, it must yet be as moist as is compatible with its cohering sufficiently to hold together; and being thus prepared, it must be put upon the model, and compressed with the hand, or any flat instrument, that the parts of it may adapt themselves in the most perfect manner to those of the subject, as well as to be compact with respect to themselves. When the model is so covered to a convenient thickness, the whole must be left at rest till the plaster be set and firm, so as to bear dividing without falling to pieces, or being liable to be easily put out of its form: it must then be divided into pieces, in order to its being

taken off from the model, by cutting it with a knife with a very thin blade; and being divided, it must be cautiously taken off and kept till dry; but it must be always carefully observed, before the separation of the parts be made, to knotch them across the joints or lines of the division at proper distances, that they may with ease and certainty be conjoined again. The art of properly dividing the moulds, in order to make them separate from the model, requires more dexterity and skill than anything else in the art of casting, and does not admit of rules for the most advantageous conduct of it in every case. Where the subject is of a round or spheroidal form, it is best to divide the mould into three parts, which will then easily come off from the model; and the same will hold good of a cylinder or any regular curved figure.

The mould being thus formed and dried, and the parts put together, it must be greased, and placed in such a position that the hollow may lie upwards, and then filled with plaster mixed with water, in the same proportion and manner as was directed for the casting of the mould; and when the cast is perfectly set and dry, it must be taken out of the mould, and repaired where it is necessary; which finishes the operation.

This is all that is required with respect to subjects where the surfaces have the regularity above mentioned; but where they form curves which intersect each other, the conduct of the operation must be varied with respect to the manner of taking the cast of the mould from off the subject or model; and where there are long projecting parts, such as legs or arms, they should be wrought in separate casts. The operator may easily judge from the original subjects which parts will come off together, and which may require to be separated. The principle of the whole consists only in this, that where under-workings as they are called occur, that is, wherever a straight line drawn from the basis or insertion of any projection would be cut or crossed by any part of such projection, this part cannot be taken off without a division, which must be made either in the place where the projection would cross the straight line, or, as that is frequently difficult, the whole projection must be separated from the main body, and divided also lengthwise into two parts; and where there are no projections from the principal surfaces, but the body is so formed as to render the surface a composition of such curves that a straight line drawn parallel to the surface of one part would be cut by the outline in one or more places of another part, a division of the whole should be made, so as to reduce the parts of it into regular curves, which must then be treated as such. For casting figures in very high relief, the late Sir Francis Chantrey and Mr Steell of Edinburgh have formed the models for their moulds of fine well-tempered clay, and availed themselves of the plasticity of that material to draw carefully forward the parts of the subject intended to be most prominent; by which arrangement division of the model into parts is much obviated, and great boldness is communicated to the design.

In larger masses, where there would otherwise be a great thickness of the plaster, a core or body may be put within the mould, in order to produce a hollow in the cast, which both saves the expense of material, and renders the cast lighter.

This core may be of wood where the forming of a hollow of a straight figure or a conical one with the basis outward will answer the end; but if the cavity require to be round, or of any curve figure, the core cannot then be drawn while entire, and consequently should be of such matter as may be taken out piece-meal. In this case the core is best formed of clay, which must be worked upon wires to give it tenacity, and suspended in the hollow of the mould by cross wires lying over the mouth; and when the plaster is sufficiently set to bear handling, the clay must be picked out by a proper instrument.

Where it is desired to render the plaster harder, the water with which it is tempered should be mixed with parchment size properly prepared, which will make it very firm and tenacious.

In the same manner, figures, busts, and the like, may be cast of lead or any other metal in the moulds of plaster; only the expense of plaster, and the tediousness of its becoming sufficiently dry, when in a very large mass, to bear the heat of melted metal, render the use of clay, compounded with some other proper materials, preferable where large subjects are in question. The clay in this case should be kneaded and washed till it be perfectly free from gravel or stones, and then mixed with a third or more of fine sand, to prevent it cracking; or, instead of sand, coal ashes sifted fine may be used. Whether plaster or clay be employed for the casting in metal, it is extremely necessary to have the mould perfectly dry, otherwise the moisture, being rarefied, will cause an explosion that will blow the metal out of the mould, and endanger the operator, or at least crack the mould in such a manner as to frustrate the operation. Where the parts of a mould are large, or project much, and consequently require a greater tenacity of the matter they are formed of to keep them together, flocks of cloth, prepared like those designed for paper-hangings, or fine cotton plucked or cut till it is very short, should be mixed with the ashes or sand before they are added to the clay to make the composition for the mould. The proportion should be according to the degree of cohesion required; but a small quantity will answer the end if the other ingredient of the composition be good, and the parts of the mould properly linked together by means of the wires above directed.

There is a method of taking casts in metals from small animals, and the parts of vegetables, which may be practised for some purposes with advantage, particularly for the decorating of grottos or rock works with lizards, snakes, frogs, birds, or insects, which should be properly coloured to render the imitation complete.

This is to be performed by the following method: A coffin or proper chest for forming the mould being prepared of clay, or four pieces of boards fixed together, the animal or parts of vegetables must be suspended in it by a string, and the leaves, tendrils, or other detached parts of the vegetables, or the legs, wings, and other parts of the animals, properly separated and adjusted in their right position by a small pair of pincers; a due quantity of plaster of Paris and calcined talc, in equal quantities, with some fibrous native alum, must then be tempered with water to the proper consistence for casting, and the subject from which the cast is to be taken, as also the sides of the coffin, moistened with spirit of wine. The coffin or chest must then be filled with the tempered composition of the plaster and talc, putting at the same time a piece of straight stick or wood to the principal part of the body of the subject, and pieces of thick wire to the extremities of the other parts, in order that they may form, when drawn out after the matter of the mould is properly set and firm, a channel for pouring in the melted metal, and vents for the air, which otherwise, by the rarefaction it would undergo from the heat of the metal, would force its way out or burst the mould. In a short time the plaster and talc will set and become hard, when the stick and wires may be drawn out, and the frame or coffin in which the mould was cast taken away; and the mould must then be put first into a moderate heat, and afterwards, when it is as dry as it can be rendered by that degree of heat, removed into a greater, which may be gradually increased till the whole be red-hot. The animal or part of any vegetable which was included in the mould will then be burnt to a coal, and may be totally calcined to ashes, by blowing for some time gently into the channel and passages made for pouring in the metal, and giving vent to the air, which will

at the same time that it destroys the remainder of the animal or vegetable matter, blow out the ashes. The mould must then be suffered to cool gently, and will be perfect, the destruction of the substance of the animal or vegetable having produced a hollow of a figure correspondent to it; but it may be nevertheless proper to shake the mould, and turn it upside down, as also to blow with the bellows into each of the air vents, in order to free it wholly from any remainder of the ashes; or where there may be an opportunity of filling the hollow with quicksilver without expense, it will be found a very effectual method of clearing the cavity, as all dust, ashes, or small detached bodies, will necessarily rise to the surface of the quicksilver, and be poured out with it. The mould being thus prepared, it must be heated very hot when used if the cast be made with copper or brass; but a less degree will serve for lead or tin; and the matter being poured in, the mould must be gently struck, and then suffered to rest till it be cold, at which time it must be carefully taken from the cast, but without the least force; for such parts of the matter as appear to adhere more strongly must be softened by soaking in water till they be entirely loosened, that none of the more delicate parts of the cast may be broken off or bent.

Where the *alumen plumosum* cannot easily be procured, the plaster may be used alone; but it is apt to be calcined by the heat used in burning the animal or vegetable from which the cast is taken, and to become of too incohering and crumbly a texture; or, for cheapness, Stourbridge or any other good clay, washed till it be perfectly fine, and mixed with an equal portion of sand, and some flocks cut small, may be employed. Pounded pumice-stone and plaster of Paris, taken in equal quantities, and mixed with washed clay in the same proportion, is said to make excellent moulds for this and similar purposes.

Casts of medals, or such small pieces as are of a similar form, may be made in plaster by the method directed for bas-reliefs. Indeed nothing more is required than to form a mould by laying them on a proper board, and having surrounded them by a rim made by a piece of card, or any other pasteboard, to fill the rim with soft tempered plaster of Paris; which mould, when dry, will serve for several casts. It is nevertheless a better method to form the mould of melted sulphur, which will produce a sharper impression in the cast, and be more durable than those made of plaster. Casts are likewise frequently made of sulphur, which being melted, must be treated exactly in the same manner as plaster.

For taking casts from medals Dr Lewis recommends a mixture of flowers of brimstone and red lead. Equal parts of these are to be put over the fire in a ladle till they soften to the consistence of pap; then they are to be kindled with a piece of paper, and stirred for some time. The vessel being afterwards covered close, and continued on the fire, the mixture grows fluid in a few minutes. It is then to be poured on the metal, previously oiled and wiped clean. The casts are very neat, and their colours sometimes a pretty deep black, sometimes a dark gray. They are very durable; and when soiled, may be washed clean in spirits of wine.

Dr Lettsom recommends tin-foil for taking off casts from medals. The thinnest kind is to be used. It should be laid over the subject from which the impression is to be taken, and then rubbed with a brush, the point of a skewer, or a pin, till it has perfectly received the impression. The tin-foil should now be pared close to the edge of the medal, till it be brought to the same circumference. The medal must then be reversed, and the tin-foil will drop off into a chip-box or mould placed ready to receive it. Thus the concave side of the foil will be uppermost, and upon this plaster of Paris, prepared in the usual manner, may be poured. When dry the whole is to be taken out, and the tin-foil sticking on the plaster will give a perfect representation of the medal, almost equal in beauty to silver. If the box or mould is a little larger than the medal, the plaster running round the tin-foil will give the appearance of a white frame or circular border, and hence the new made medal will appear neater and more beautiful.

Casts may likewise be made with iron prepared in the following manner: "Take any iron bar, or piece of a similar form, and, having heated it red hot, hold it over a vessel containing water, and touch it very slightly with a roll of sulphur, which will immediately dissolve it, and make it fall in drops into the water. As much iron as may be wanted being thus dissolved, pour the water out of the vessel, and pick the drops formed by the melted iron from those of the sulphur, which contain little or no iron, and will be distinguishable from the other by their colour and weight." The iron will by this means be rendered so fusible that it will run with less heat than is required to melt lead, and may be employed for making casts of medals, and many other such purposes, with great convenience and advantage.

Impressions of medals having the same effect as casts may be made also of isinglass-glue, by the following means: Melt the isinglass, beaten, as when commonly used, in an earthen pipkin, with the addition of as much water as will cover it, stirring it gently till the whole be dissolved; then with a brush of camel's hair cover the medal, which should be previously well cleansed and warmed, and then laid horizontally on a board or table, greased in the part around the medal. Let them rest afterwards till the glue be properly hardened; and then, with a pin, raise the edge of it, and separate it carefully from the medal. The cast will be thus formed by the glue as hard as horn, and extremely light. In order to render the relief of the medal more apparent, a small quantity of carmine may be mixed with the melted isinglass; or the medal may be previously coated with leaf-gold by breathing on it, and then laying on the leaf, which will by that means adhere to it; but the use of leaf gold is apt to impair a little the sharpness of the impression.

Impressions of medals may likewise be taken in putty; but it should be the true kind, made of calx of tin and drying oil. These may be formed in the moulds, previously taken in plaster or sulphur; or moulds may be made in its own substance, in the manner directed for those of the plaster. These impressions will be very sharp and hard; but the greatest disadvantage that attends them is their drying very slowly, and being liable in the meantime to be damaged.

Impressions of prints or other engravings may be taken from copperplates, by cleansing them thoroughly, and pouring plaster upon them; but the effect in this way is not strong enough for the eye, and therefore the following method is preferable, where such impressions on plaster are desired: Take vermillion, or any other coloured pigment, finely powdered, and rub it over the plate. Then pass a folded piece of paper, or the flat part of the hand, over the plate, to take off the colour from the lights or parts where there is no engraving; the proceeding must then be the same as where no colour is used. This last method is also applicable to the making of impressions of copperplates on paper with dry colours; for the plate being prepared as here directed, and laid on the paper properly moistened, and either passed under the rolling press, or any other way strongly forced down on the paper, an impression of the engraving will be obtained.

Impressions may likewise be taken from copperplates, either on plaster or paper, by means of the smoke of a candle or lamp; if, instead of rubbing them with any colour, the plate be held over the candle or lamp till the whole surface become black, and then wiped off by the flat of the hand, or paper.

Castle.

These methods are not, however, of great use in the case of copperplates, except where impressions may be desired on occasions where printing ink cannot be procured. But as they may be applied likewise to the taking of impressions from snuff-boxes, or other engraved subjects, by which means designs may be instantly borrowed by artists or virtuosi, they may in such instances be very useful.

The expedient of taking impressions by the smoke of a candle or lamp may be employed also for botanical purposes in the case of leaves; as a perfect and durable representation not only of the general figure, but of the contexture and disposition of the larger fibres, may be extemporaneously obtained at any time. The same may be nevertheless done in a more perfect manner by the use of linseed oil, either alone, or mixed with a small proportion of colour, where the oil can be conveniently procured; but the other method is valuable on account of its being practicable at almost all seasons, and in all places, within the time that the leaves will keep fresh and plump. In taking these impressions it is proper to bruise the leaves, so as to take off the projections of the large ribs, which might prevent the other parts from plying to the paper.

CASTLE (Saxon *castel*, Latin *castellum*, from *castrum*), a fortress or place rendered defensible either by nature or art. It is also frequently applied to the principal mansion of a prince or nobleman. In the time of Henry II., there were no less than 1115 castles in England, each of which was a manor.

Castles walled with stone, and designed for residence as well as defence, are for the most part, according to Grose, of no higher antiquity than the Conquest; for although the Saxons, Romans, and even, according to some writers on antiquity, the ancient Britons, had castles built of stone, yet these were both few and so much decayed, that little more than their ruins remained. This is asserted by many of our historians and antiquaries, and assigned as a reason for the facility with which William the Norman made himself master of this country. This circumstance was not overlooked by so good a general as the Conqueror; who, in order effectually to guard against invasions from without, as well as to awe his newly-acquired subjects, immediately began to erect castles all over the kingdom, and likewise to repair and augment the old ones. Besides, as he had parcelled out the lands of the English amongst his followers, they, to protect themselves from the resentment of the despoiled natives, built strongholds and castles on their estates; and these were multiplied so rapidly, that towards the latter end of the reign of king Stephen, they amounted to the enormous number of 1115.

As the feudal system gathered strength, these castles became the heads of baronies. Each castle was a manor, and its castellan, owner, or governor, the lord of that manor. Markets and fairs were directed to be held there, not only to prevent frauds in the king's duties or customs, but also as these were esteemed places where the laws of the land were observed, and as such had a very particular privilege. But this good order did not last long, for the lords of castles began to arrogate to themselves a royal power, not only within their castles, but likewise in their environs; exercising judicature both civil and criminal, coining money, and arbitrarily seizing forage and provisions for the subsistence of their garrisons, which they afterwards demanded as a right. At length their insolence and oppression grew to such a pitch, that, according to William of Newbury, "there were in England as many kings, or rather tyrants, as lords of castles;" and Matthew Paris emphatically styles them "nests of devils and dens of thieves." Castles were not solely in the possession of the crown and the lay barons, but even bishops had such fortresses, though it seems to have been contrary to the canons, from a plea made use of in a general council in favour of king Stephen, who had seized upon the strong castles of the bishops of Lincoln and Salisbury. This prohibition, if such existed, was, however, very little regarded; and in the following reigns many strong places were held, and even defended, by the ecclesiastics; nor was greater obedience afterwards paid to a decree made by the pope at Viterbo, on the fifth of the kalends of June 1220, in which it was ordained that no person in England should keep in his hands more than two of the king's castles.

Castle.

The licentious behaviour of the garrisons of these places having become intolerable, it was agreed, in the treaty between Stephen and Henry II., when only duke of Normandy, that all the castles built within a certain period should be demolished; in consequence of which many were actually rased, but not the number stipulated.

The few castles in existence under the Saxon government were probably, on occasions of war or invasion, garrisoned by the national militia, and at other times slightly guarded by the domestics of the princes or great personages who resided in them; but after the conquest, when all the estates were converted into baronies held by knight's service, castle-guard, coming under that denomination, was among the duties to which particular tenants were made liable. From these services the bishops and abbots, who till the time of the Normans had held their hands in frank almoign, or free alms, were, by this new regulation, not exempted; they were not, however, like the laity, obliged to render personal service, it being sufficient that they provided fit and able persons to officiate in their stead. This was at first stoutly opposed by Anselm, archbishop of Canterbury, who being obliged to find some knights to attend king William Rufus in his wars in Wales, complained of it as an innovation and infringement of the rights and immunities of the church.

It was no uncommon thing for the kings of those days to grant estates to men of approved fidelity and valour, on condition that they should perform castle-guard in the royal castles, with a certain number of men, for some specified time; and sometimes they were likewise bound by their tenures to keep in repair and guard some particular tower or bulwark, as was the case at Dover Castle.

In process of time these services were commuted for annual-rents, sometimes styled *wardpenny*, and *waytfee*, but commonly *castle-guard* rents, payable on fixed days, under prodigious penalties called *sursizes*. At Rochester, if a man failed in the payment of his rent of castle-guard on the feast of St Andrew, his debt was doubled every tide while the payment was delayed. These were afterwards restrained by an act of parliament made in the reign of Henry VIII., and finally annihilated, with the tenures by knight's service, in the time of Charles II. Such castles as were private property were guarded either by mercenary soldiers, or by the tenants of the lord or owner.

Castles which belonged to the crown, or fell to it either by forfeiture or escheat (circumstances that frequently happened in the distracted reigns of the feudal times), were generally committed to the custody of some trusty person, who seems to have been indifferently styled governor and constable. Sometimes also they were put into the possession of the sheriff of the county, who often converted them into prisons. That officer was then accountable at the exchequer for the farm or produce of the lands belonging to the places intrusted to his care, as well as for all other profits; and he was likewise, in case of war or invasion, obliged to victual and furnish them with munitions out of the issues of his county, to which he was directed by writ of privy seal.

The situation of the castles of the Anglo-Norman kings and barons was most commonly an eminence, and near a river; a position on several accounts eligible. The whole site of the castle, which was frequently of great extent and irregular figure, was surrounded by a deep and broad

ditch, called the *fosse*, sometimes filled with water, and sometimes dry. Before the great gate was an outwork, called a *barbacan* or *antemural*, which was a strong high wall, surmounted with turrets, designed for the defence of the gate and drawbridge. On the inside of the ditch stood the wall of the castle, about eight or ten feet thick, and between twenty and thirty feet high, with a parapet, and a kind of embrasures called *crennels* on the top. On this wall, at proper distances, were built square towers of two or three stories high, which served for lodging some of the principal officers of the proprietor of the castle, and for other purposes; and on the inside were erected lodgings for the common servants or retainers, granaries, storehouses, and other necessary offices. On the top of this wall, and on the flat roofs of these buildings, stood the defenders of the castle, when it was besieged, who thence discharged arrows, darts, and stones on the besiegers. The great gate of the castle stood in the course of this wall, and was strongly fortified with a tower on each side, and rooms over the passage, which was closed with thick folding doors of oak, often plated with iron, and with an iron portcullis or grate let down from above. Within this outward wall was a large open space or court, called, in the largest and most perfect castles, the *outer bayle*, or *ballium*, in which stood commonly a church or chapel. On the inside of this outer bayle was another ditch, wall, gate, and towers, inclosing the inner bayle or court, within which the chief tower or *keep* was built. This was a large square fabric, four or five stories in height, having small windows in prodigiously thick walls, which rendered the apartments within it dark and gloomy. This great tower was the palace of the prince, prelate, or baron, to whom the castle belonged, and the residence of the constable or governor. Under ground were dismal dark vaults, for the confinement of prisoners, and sometimes called the *dungeon* or *donjon*. In this building also was the great hall, in which the owner displayed his hospitality, by entertaining his numerous friends and followers. At one end of the great halls of castles, palaces, and monasteries, there was a place raised a little above the rest of the floor, called the *dais*, where the chief table stood, at which persons of the highest rank dined. Though there were unquestionably great variations in the structure of castles, yet the most perfect and magnificent of them seem to have been constructed nearly on the plan here described. Such, for example, was the famous castle of Bedford, as appears from the account of the manner in which it was taken by Henry III., A.D. 1224. The castle fell after four assaults. In the first was taken the barbacan; in the second the outer ballia; in the third attack, the wall by the old tower was thrown down by the miners, where, with great danger, they possessed themselves of the inner ballia, through a chink; in the fourth assault the miners set fire to the tower, so that the smoke burst out, and the tower itself was rent so as to show some broad chinks; upon which the enemy surrendered.

Before the accession of James VI. to the throne of England, the situation of Scotland was such that every baron's house was more or less fortified, according to the power or consequence of its lord, or according to the situation of the castle. Near Edinburgh or Stirling, where the inhabitants were somewhat polished in their manners, and overawed by the seat of government, no more was necessary than towers capable of resisting the cursory attacks of robbers and thieves, who never durst stop to make a regular investment, but plundered by surprise, and, if repulsed, instantly fled. But, when further removed, as in Perthshire, Inverness-shire, or Aberdeenshire, then it was necessary to be better defended; and the aids of a peel or dungeon, with outer walls, moat, wet ditch, and barnakin, were added, to enable the lord of the keep to resist the formidable attack of his powerful adversary. The history of Scotland, so late as the reign of the Stuart family, affords a number of melancholy instances of inveterate feuds among the greater and lesser barons of that period, when every mode of fortification then in use was seldom adequate to the defence of the castle against the storm or blockade of the enraged chieftain. The third kind of fortresses which we meet with in Scotland consists of those situated on the borders of England, or on the sea-coasts of the kingdom, and in the Western Isles, and in very remote places. Many of the old castles in Scotland were situated on an island in a deep lake, or on a peninsula, which, by a broad deep cut, was made an island. This kind of fortress was only accessible in a hard frost, or by boats, which were not easily transported by a people destitute of good roads and wheel-carriages. In fact they could only be taken by surprise or blockade, the first of which was difficult, and the second tedious; so that, before the use of artillery, they might be deemed almost impregnable. On this account their situation was very desirable in the inland parts of Scotland. On the sea-coasts of Scotland we generally find the strongest and most ancient, as well as the most impregnable castles, since these had to defend themselves from the invasion of the foreign enemy, as well as the attacks of the domestic foe. Thus the barons whose lands extended to the sea-coast, perched, like the eagle, on the most inaccessible rocks that lay within their possessions.—(See Grose's *Antiquities;* King's *Munimenta Antiqua;* Roy's *Military Antiquities of the Romans in Britain;* Britton's *Architectural Antiquities;* Brayley's *Ancient Castles of England and Wales.*)

Castle, in old writers, is also used for a fortified town or village.

Castle-Stead an appellation given by the country people in the north of England to the Roman *castella*, as distinguished from the *castra stativa*, which they usually call *chesters*. Horsley represents this as a useful criterion by which to distinguish a Roman camp or station. There are several of these castella on Severus's wall. They are generally sixty feet square; their northern side is formed by the wall itself, which falls in with them; the intervals between them are from six furlongs and a half to seven; and they seem to have stood closest where the stations are widest apart.

CASTLEBAR, a town of Ireland, in the county of Mayo, pleasantly situated on the river of the same name, 159 miles west by north of Dublin. It consists chiefly of a main street upwards of half a mile in length, and a square There is a court-house, jail, parish church, Roman Catholic chapel, infirmary, two dispensaries, linen hall, savings-bank, artillery and infantry barracks, and workhouse. It has some breweries, and a considerable trade in linens. Pop (1851) 6020, including workhouse, infirmary, and jail.

CASTLEBLAYNEY, a pleasantly-situated and well-built town of Ireland, in the county of Monaghan, 14 miles S.E. of Monaghan, and 62 miles from Dublin. It has a church and several chapels, market-house, workhouse, hospital, bridewell, &c. Pop. (1851) including workhouse, 2841, principally engaged in the linen trade.

CASTLECARY, a station on the Edinburgh and Glasgow railway, 9 miles W.S.W. of Falkirk. Here was one of the principal stations of the wall of Antoninus; and in 1770 some workmen, while searching for stones for the canal which passes near it, discovered the foundations of eight apartments of stone, one of which contained a number of erect stones, probably the remains of the hypocaust of a bath, with marks of fire upon them. In a hollow of the rock near this place, about 100 quarters of wheat, black through age, were found in 1771, with some wedges and hammers supposed to be Roman. The formation of the Edinburgh and Glasgow railway has almost entirely obliterated this remarkable fort.—(See Stuart's *Caledonia Romana*, edited by David Thomson. 4to, 1852.)

Castlecary, in Somerset, a town of 1912 inhabitants.

CASTLECOMER, a town of Ireland, county of Kilkenny, on the river Deen, 10 miles north of Kilkenny. It is neat and well-built, and has a church, a Roman Catholic chapel, court-house, market-house, hospital, and infantry barracks. Pop. (1851) 1724, chiefly engaged in the extensive collieries about two miles distant.

CASTLE-DERMOT, or TRISTLE DERMOT, an ancient town of Ireland, county of Kildare, on the river Lerr, 6 miles N. by E. of Carlow, and 53 from Dublin. An abbey was founded here by St Diermid in 550. Among its antiquities are the remains of a large cathedral, part of which is now used as a parish church; a Franciscan monastery; a priory; a castle; a strong square tower; several crosses; and other ancient remains. It was the residence of the Dermots, kings of Leinster. Pop. (1841) 1416; (1851) 666.

CASTLE-DOUGLAS, a burgh of barony in Scotland, stewartry of and 9 miles N.E. of the town of Kirkcudbright. It is a neat and well-built modern town, and is indebted for its prosperity to the advancing agricultural wealth of the vicinity. The weekly corn and cattle markets formerly held at Rhone-house have been transferred to Castle-Douglas. Pop. (1851) 1992.

CASTLE-ISLAND, a small town of Ireland, county of Kerry, 11 miles E.S.E. of Tralee. Its principal edifices are the parish church, Roman Catholic chapel, session-house, and prison. The castle, from which the place derives its name, was erected by Geoffry de Mariscis, lord-justice of Ireland, in 1226, and was frequently the subject of violent contention. Pop. (1851) including workhouse, 2582.

CASTLEREAGH, a market-town of Ireland, county Roscommon, 17 miles W.N.W. from Roscommon. It is pleasantly situated on the river Suck, which is here crossed by two bridges. The town consists principally of one long, wide, and tolerably well-built street; and has a church, workhouse, bridewell, dispensary, and distillery. In the immediate vicinity is the extensive demesne of Castlereagh, the seat of Lord Mountsandford. Pop. in 1851 (including 1392 in workhouse), 2613.

CASTLETOWN, the capital of the Isle of Man, and seat of the Manx government, stands on the western side of Castletown bay, 11 miles S.W. of Douglas. It is a neat and regularly built town, and has a large square containing some handsome houses. Castle-Rushen, said to have been built about 960 by the Danish chief Guttred, and afterwards the residence of the kings of Man, stands in the centre of the town, and is now partly used as a prison and barracks. Castletown has a church, three chapels, market-house, college, bank, and literary society. Pop. 2579.

CASTOR. See BEAVER; and index to MAMMALIA.

CASTOR, a moiety of the constellation Gemini. It is also called Razalgenze, Apollo, Aphellan, Avellar, and Anelar. Its latitude northwards for the year 1700, according to Hevelius, was 10. 4. 23, and its longitude of Cancer 17. 4. 14.[1]

CASTOR-OIL is extracted from the seeds of the *Ricinus communis*, a plant belonging to the natural order *Euphorbiaceæ*, and to the Linnæan class and order *Monœcia Monadelphia*. This plant, common in Asia, Africa, West Indies, south of Europe, &c., is best known by the name of the Palma Christi, and is now recognised as the gourd (kikayon and kiki) mentioned in Scripture as sheltering the prophet Jonah. In temperate countries this plant is annual and herbaceous, and only reaches 6 or 8 feet in height. But in warmer countries it is more ligneous and perennial, and in India often attains the height of 40 feet. It is of rapid growth, and has large deeply-cut palmated leaves. It throws up a long spike of green flowers, which are succeeded by spiny capsules, each containing three beautifully marbled seeds. The kernel of the seeds contains about 46 per cent. of a fixed oil, which is the castor-oil of commerce. The oil was well known to, and was used by the ancient Egyptians, Greeks, and probably all the oriental nations. In India it is largely used at the present day; and though sometimes obtained by expression, is more commonly prepared by steeping the seeds for a night in cold water, boiling them for two hours, then drying them in the sun, and afterwards pounding or bruising them: the seeds thus bruised are then thrown into water and boiled till the whole oil is extracted, when it rises to the surface and is skimmed off. In the West Indies the seeds are not usually either steeped or boiled previous to bruising, but are bruised and boiled in water at once. At one time, both in India and in London (as still in America), the seeds were bruised, and the oil obtained by subjecting the mass to strong expression. When so prepared the oil requires to be boiled with water, or at least subjected along with water to a heat of 200°, in order to coagulate the albumen and dissolve out the mucilage which has been expressed along with the oil, and which, if not removed, would cause the oil soon to become rancid. When thus prepared by expression it is called *cold drawn* castor-oil, and used to be most in esteem; but oil so prepared has no advantages over that prepared carefully by boiling the bruised seeds. The chief supply comes from India. When good it should be a thickish fluid, either limpid or of a very pale yellow colour, with a peculiar nauseous odour, and an oily taste which is very permanent. This oil may be distinguished from almost every other fixed oil by being soluble in ether or in alcohol in all proportions. Hence one of the best tests of its purity is to mix it with its own volume of alcohol. If it be entirely dissolved it is pure; if impure, the oil mixed with it is left undissolved. Bussy and Lecanu regard the oil as composed of three fatty acids; but other chemists dissent from this, and seeing that it is not separable with margarine and elaine, like the other oils, and that it is totally soluble in alcohol and ether, regard it as composed of a single peculiar fatty principle. The principle, however, on which its purgative properties depend has not yet been discovered.

In all countries where the castor-oil plant grows, the oil is extensively used for burning; but it is best known for its use in medicine, as one of our best and safest purgatives. It is usually administered plain, or mixed with milk, coffee, port wine, brandy, or aromatic waters, to cover its nauseous taste; or is formed into a soapy emulsion with a few drops of solution of caustic potass. The castor-oil seeds are themselves powerfully drastic purgatives and irritants, so few as twenty seeds having even proved fatal to man. The kernels of from one to three of the fresh seeds suffice for an effectual dose.

Castor-oil pays no duty now; it is therefore difficult to procure late returns of its importations. In 1835 there were imported into Great Britain 1,109,307 lb., of which 670,205 lb. were retained for home consumption.

CASTOR and *POLLUX*. See DIOSCURI.

CASTOR and *POLLUX*, a fiery meteor, which at sea appears sometimes adhering to a part of the ship, in form of one, two, or even three or four fire-balls. When one is seen alone, it is properly called *Helena;* two are denominated Castor and Pollux, and sometimes Tyndaridæ. Castor and Pollux by the Spaniards are called San Elmo; by the French, St Elme, St Nicholas, St Clare, St Helene; by the Italians, Ermo; by the Dutch, Tree Vuuren.

Castor and Pollux are commonly believed to indicate a cessation of the tempest: Helena alone, to portend a severer storm.

CASTOREUM or CASTOR, a peculiar secretion of the *castor fiber* or beaver. It is used in medicine as an antispasmodic. See BEAVER.

[1] For some interesting observations on this double star, see *Mem. R. Astronom. Soc.* v. 196.

CASTRATION, the operation of depriving a male animal of the capacity of generation.

Castration is common in the East, especially among the Turks, who emasculate their slaves, particularly those attached to the harem. The Persians and others had various methods of making eunuchs; namely, by the administration of cicuta and other poisonous herbs, which, according to Paulus Ægineta, have the same effect; or leaving the organs entire, but dividing the vessels, so as to render the parts lax and weak.

Athenæus relates that Andramyles, king of Lydia, castrated women; and Hesychius and Suidas state that Gyges did the same. Dalecampius, however, remarking on the passage of Athenæus alluded to, maintains that it merely refers to an artificial kind of protection. The effect of castration on the voice is well known. It is said that within a very recent period *castrati* were found among the singers in the papal chapel; but if this still be the case, there seems every probability that the disagreeable effect of the association connected with this peculiarity of voice will soon render obsolete the practice of castration for such a purpose. See Eunuch.

By the civil law it is penal in physicians and surgeons to castrate, even with consent of the party, who is himself included in the same penalty, and his effects forfeited. The offence of mayhem by castration is, according to our old writers, felony, although committed upon the highest provocation. See a record of Henry III. to this purport, transcribed by Sir Edward Coke, 3 Inst. 62.

CASTRES, capital of an arrondissement of the same name in the department of Tarn, France, 23 miles S.E. of Alby, stands in a pleasant and fertile valley, on both sides of the Agout, here crossed by two bridges. The town is ill-built, and the streets are narrow and crooked; but it has of late been much improved. The principal buildings are the town-hall, formerly the episcopal palace, the churches of St Benoit and Notre-Dame, two hospitals, barracks, theatre, and exchange. It is the seat of tribunals of primary instance and commerce, and of a Protestant consistory. Castres is celebrated for its manufactures, among which are woollen, linen, silk and cotton stuffs, soap, leather, paper, and iron and copper wares. It has also a considerable trade. Dacier, Rapin, and Sabatier were natives of this town. Pop. (1851) 19,098.

CASTRO, a seaport-town of Naples, in the province of and 10 miles S.W. of the town of Otranto. It is the seat of a bishopric, and has an old castle, cathedral, and some export trade in corn, wine, fish, &c. The harbour, however, is accessible only to small vessels. Pop. 7000.

Castro *Giovanni*, the ancient *Enna*, a town of Sicily, province of Catania, on the summit of a lofty and nearly inaccessible mountain in the centre of the island, and about 4000 feet above the level of the sea. The principal edifice is the castle, which is fast going to decay. The town is well supplied with water, the atmosphere salubrious, and the surrounding country very fertile. In ancient times it was one of the chief seats of the worship of Ceres, and had a celebrated temple of that goddess. About 5 miles from the town, at the foot of the mountain, is the lake of Pergusa, from the banks of which it is said that Proserpine was carried off by Pluto. Pop. 11,000.

Castro *Nuovo*, a town of Sicily, in the intendancy of Palermo, 25 miles north of Girgenti. Pop. 6500. In the vicinity there are extensive quarries of fine marble.

Castro *Reale*, a city of the intendancy of Messina, in the island of Sicily situated on a triangular and rocky mountain. The climate is salubrious; and excellent wine and oil are produced here. This city is 150 miles from Palermo. Pop. about 11,000.

Castro *del Rio el Real*, a town in the province of Cordova, Spain. It is situated near the river Guadajocillo, about 16 miles S.E. from Cordova, and contains several churches, schools, and hospitals, a handsome town-house and prison. Its population is rather more than 9000, the great majority of whom are employed in agricultural pursuits. Its commerce is confined to the exportation of grain and oil, and its industry to coarse manufactures for domestic purposes.

Castro *Urdiales*, a seaport-town of Spain, in the province of Santander, is well known to sailors for the shelter which it affords from storms in the Bay of Biscay. It was destroyed by General Foy in 1813, but has been rebuilt, fortified, and greatly improved. The most remarkable buildings are the castle and the hermitage of Santa Ana. Its fisheries are considerable. Pop. 2936.

Castro *Villari*, a town of Naples, in the province of Calabria Citra, 8 miles W.N.W. of Cassano. It stands on an eminence surrounded by lofty mountains, and the modern portion contains several handsome streets. The massive castle is supposed to belong to the Norman period. It carries on a considerable trade in cotton, wine, fruits, &c., and has about 5000 inhabitants.

CASTRUCCIO Castracani, a celebrated Italian general, was born at Lucca in Tuscany in 1284. Being exposed as an infant in a vineyard, he was found by Dianora, a widow lady of the family of the Castracani, who brought him up and educated him as her own. She intended him for the priesthood; but he was scarcely fourteen years old when he began to devote himself to military sports and those athletic exercises which suited his great strength of body. The factions of the Guelfs and Ghibellines then shared all Italy between them; dividing not only popes and emperors, but those of the same town, and even members of the same family. Francis Guinigi, a leader of the Ghibelline party, observing Castruccio's spirit and ability, prevailed with Antonio, the brother of Castruccio's guardian, to permit him to become a soldier. Castruccio soon became an adept in military tactics, and was made lieutenant of a company of foot by Guinigi. In his first campaign the fame of his courage and conduct spread over all Lombardy; and soon afterwards Guinigi when dying committed to him the care of his son and the management of his estate. His exploits, however, provoked the envy of his commander-in-chief, who by stratagem procured his imprisonment in order to put him to death. He obtained his release; and the people of Lucca, in gratitude for his former services, chose him as their sovereign prince. The Ghibellines regarded him as the chief of their party; and those who had been banished from their country fled to him for protection, and unanimously promised that if he could restore them to their estates, they would serve him so effectually that the sovereignty of their country should be his reward. Flattered by these promises, he entered into a league with the prince of Milan; and kept his army constantly on foot, employing it as best suited his own designs. For the services he had rendered the pope, he was made senator of Rome with more than ordinary ceremony; but during his residence at the capital he received news which obliged him to hasten back to Lucca. The Florentines proclaimed war against him; but Castruccio routed their army, and the supreme authority of Tuscany was about to fall into his hands, when a period was put to his life. In May 1328 he gained a complete victory over his enemies, amounting to 30,000 foot and 10,000 horse; and 22,000 of them were slain, while the loss on his part fell short of 1600. But as he was returning from the field of battle, tired and heated with the action, he halted a while, in order to address his soldiers as they passed; an imprudence which proved fatal to him, for he was immediately seized with an ague, at first neglected, but which carried him off in a few days, in the forty-fourth year of his age. Machiavelli, who has written the life of Castruccio, says that he was not only an

extraordinary man in his own age, but that he would have been so in any other.

CASTRUM DOLORIS (i. e. *castle of grief*), a catafalco, or rather the chamber or chapel in which is erected a catafalque or lofty tomb of state, containing the coffin of a prince or other distinguished person, and decorated with armorial bearings, inscriptions, arms, &c., brilliantly illuminated with tapers. By the French the *castrum doloris* is termed *chapelle ardente*. This latter is to be distinguished from *chambre ardente*, which formerly in France was a chamber hung with black cloth, in which state prisoners of high rank were tried by torchlight.

CASUALTY, an accident, or that which happens by chance; more particularly an accident causing death.

CASUIST, one who studies and resolves cases of conscience. The Jesuit Escobar has made a collection of the opinions of all the casuists before him. M. le Féore, preceptor of Louis XIII., called the books of the casuists expositions of the "art of quibbling with God." Mayer has published a Bibliotheca of Casuists, divided into three heads —Lutheran, Calvinist, and Romish.—(See Jeremy Taylor's *Ductor Dubitantium.*)

CASUISTRY, the science or doctrine of cases of conscience; the science of resolving cases of doubtful propriety, or of determining the lawfulness or unlawfulness of what a person may do, by rules and principles derived from the Scriptures, the canon law, the councils and fathers, the laws of society, or from equity and natural reason. It is termed by Kant the *dialectics of conscience.*

CAT. See *index* to MAMMALIA.

CATA, a prefix of many English words derived from the Greek, signifying opposition, contrariety, under, down, downward; and sometimes used merely to express completeness or intensiveness, as in *cataclysm.*

CAT'S-EYE, or SUN-STONE, a kind of gem found chiefly in Siberia. In Latin it is called *oculus cati*, and sometimes *onycopălus*, from its white zones or rings like onyx, and its variable colours like opal. It is a sub-species of quartz, containing parallel fibres of amianthus.

CAT-GUT, a name absurdly enough given to the intestines of sheep, dried and twisted; used for the strings of violins, harps, &c., and sometimes coloured.

CAT-SALT, a name given by salt-workers to a very beautifully granulated kind of common salt.

CATACHRESIS (κατα against, and χρῆσις use), a trope which borrows a term of one idea to express another: as when Milton, in describing Raphael's descent from heaven to paradise, says he "*sails* between worlds and worlds." So in Scripture we read of the "*blood* of the grape."

CATACOMB (in low Latin *catacumbæ*, probably from κατά, and κύμβος, a cavity), a grotto or subterranean place for the burial of the dead.

The word *catacomb* is said to have been originally applied to the chapel of St Sebastian at Rome, in which the ancient Roman calendars say that the body of St Peter was deposited. The most extensive catacombs in the world are those in the Via Appia, which extend for six miles under ground. The entrance to them is in the church of St Sebastian, just without the Porta Capena. They probably were quarries originally, and seem to have been used as sepulchral chambers by the ancient Romans, being, in the opinion of many, the *puticuli*, or grave-pits for slaves, mentioned by Festus Pompeius and others. It is certain that they were used as sepulchres by the primitive Christians, who there found also an asylum in times of persecution. They contain numerous paintings of sacred subjects of the same era, interspersed with the symbol of the cross. These pictures are of considerable importance to the history of the art; as from them it would not be difficult to trace a series, almost unbroken, from the era of ancient art to the date of its reputed revival in Italy. Each catacomb is about three feet broad, and eight or ten high. Along the side walls of the galleries (which communicate with each other, and exhibit no masonry or vaulting), are the niches where the dead were deposited lengthwise parallel to the gallery, in three or four tiers, one above the other; and these were closed with tiles or slabs of marble, admirably cemented. Sometimes, though very rarely, the name of the deceased is found on the tile; frequently a palm is seen, painted or engraven, or the cipher Xp, which is commonly read *pro Christo.*

The best work on the catacombs of Rome is the rare and curious one by Antonio Bosio, entitled *Roma Sotteranea*, first published in 1 vol. folio in 1632, and afterwards in 2 vols. folio, with Latin descriptions; but the first is the most valuable. (See also Artaud, *Voyage dans les Catacombes de Rome.*) There are also ancient catacombs in the Capo di Monte at Naples, and in several other parts of the world.

The catacombs of Egypt have been described by Belzoni and many later travellers. The chambers extend a great distance under ground, and in some instances the walls are adorned with figures and hieroglyphics: in others the mummies are found in tombs ranged round the apartment and hollowed out in the rock.

The so-called catacombs of Paris, situate on the southern side of the Seine, are merely the quarries that furnished the stone of which the city was built. In these subterranean excavations were deposited the bones taken from the several cemeteries previous to the establishment of the system of extramural interment. These are piled in heaps so as to form various quaint devices. The excavations are of such extent that individuals have sometimes perished in their labyrinthine windings; but as they are in many parts knee-deep with water, they are seldom visited, nor indeed are they now open to public inspection.

CATADROMUS, in *Antiquity*, a rope stretched in a sloping direction in the theatres, down which the *funambuli* walked to show their skill. Elephants were also taught to descend the *catadromus.*

CATAFALQUE (Italian *catafalco*, a scaffold), a temporary structure of carpentry, decorated with painting and sculpture, and representing a tomb or cenotaph. The catafalque erected at Florence for the final interment of Michael Angelo was of unexampled magnificence.

CATAGOGIA, or feast of the return, a time of public rejoicing and festivity at Eryx in Sicily, to commemorate the return of Aphrodite (Venus), who was supposed at the feast of the *Anagogia* to go over to Africa accompanied by all the pigeons of the neighbourhood. At the return of the pigeons nine days after, the whole district, it is said, smelled of butter, which was regarded as a sign that the goddess had returned. (Ælian, *Hist. An.* iv.; *V. H.* i.; Athen. ix.)

CATAGRAPHA, a term used by Pliny to denote any oblique view of the countenance or figure, either in profile or otherwise; and which may be technically rendered *foreshortenings.* Catagrapha are said to have been the invention of Cimon of Cleonæ, who probably flourished in the time of Solon, though Pliny assigns him to a much earlier period. (Plin. *H. N.* xxxv. 34; Ælian. *V. H.* viii. 8.)

CATALEPSY (from the Greek word κατάληψις, a seizing), is a very rare form of disease, characterized by a sudden extinction of sensation and voluntary motion, with a peculiar rigidity of the voluntary muscles, in consequence of which the limbs retain during the paroxysm precisely the position they held at the moment of seizure, yet readily admit of and retain any other position they are made to assume. During this state the action of the heart and breathing continue, but are much slower and more feeble than during health. These fits come on at irregular intervals, and continue, when unchecked, for many years. Catalepsy is of such rare occurrence that few physicians have

seen a true case of the disease, and it has consequently been much confounded with different forms of hysteria and chorea; yet the distinction is quite marked.

The pathology of the disease is obscure; but from the cases which have been published, it appears probable that it depends either on functional disorder of the abdominal viscera reacting on the brain, or on these associated with disease of the brain itself. That the first supposition is most probably the correct one is evidenced from the fact, that the cure of the disease has been generally effected by attention to diet and regimen, the regulation of the bowels, to the restoration of suppressed secretions, and other means which improve the health and give tone to the system.

CATALOGUE, a list or enumeration of the names of men or things, disposed according to a certain order.

Catalogues of books are arranged either according to the order of the times when the books were printed, their form and size, in the alphabetical order of the authors' names, or according to the order of the subjects. Of this last kind is the *Catalogue Raisonné* (classed catalogue), in which the books are arranged under the heads of their several subjects, with a brief analysis of the contents of each. See BIBLIOGRAPHY, and LIBRARY.

CATALOGUE *of the Stars*, a list of the fixed stars, disposed in their several constellations, with the longitudes, latitudes, &c., of each, or according to their right ascensions. The first who undertook such a catalogue was Hipparchus, about the year B.C. 120. See ASTRONOMY, p. 791.

CATALONIA, in Spanish *Cataluña*, a department forming a triangle in the N.E. corner of the peninsula, is bounded N. by the Pyrenees W. by Aragon, S. by Valencia, and E. by the Mediterranean. It extends from N. Lat. 40. 30. to 42. 50., and from E. Long. 0. 12. to 3. 20. The line of sea-coast extends for about 200 miles, but is utterly destitute of good harbours, although a large portion of the population is engaged in the fisheries. The interior of the province is intersected by numerous sierras which branch off from the Pyrenees on the north, and the great central ridge which terminates in the Sierra de Llena on the S.W. Its climate and productions vary with the elevation of the surface, but there are few fertile plains, and little attention is paid to agriculture. As a manufacturing province Catalonia is the most important in Spain; but much of its commercial wealth is due to the contraband trade with France, which is easily carried on through the narrow and almost inaccessible defiles of the Pyrenees. The Catalonians generally are a powerful and hardy race, averse to the ordinary drudgery of the husbandman and mechanic, and foremost in all the revolts which have marked the political history of Spain. Catalonia is divided into the provinces of Barcelona, Tarragona, Lérida, and Gerona, the most important points in regard to which will be found under the heads of their respective capitals. The mineral wealth of the department is considerable, and consists in seams of coal, copper, lead, salt, cobalt, &c. The principal productions of the soil are corn, oil, hemp, fruits, and silk. The manufactures embrace cottons, woollens, silks, lace, leather, brandy, and wines. Area rather more than 12,000 square miles. Pop. 1,283,734.

CATAMARAN, a kind of rude raft, generally composed of three pieces of wood lashed together; used on the coasts of Coromandel and in South America, chiefly for conveying letters, messages, &c., to the shipping in the roads. It is particularly advantageous in crossing the heavy surf that always breaks on those shores.

CATANDUANES, a large island of the Philippine group, lying to the S.E. of the island of Luzon, about 36 miles in length by above 20 in breadth. It is subject to the Spaniards. The inhabitants are a barbarous race, and live by hunting and fishing.

CATANIA, the ancient *Catana*, a celebrated city and seaport of Sicily, capital of an intendancy of the same name, on the east coast of the island, at the foot of the southern projections of Mount Ætna. N. Lat. 37. 28. 20., E. Long. 15. 5. 15. Present population about 55,000. The ancient Catana was founded B.C. 730, by a colony from the neighbouring city of Naxos, which was itself founded by the Chalcidians of Eubœa. It maintained its independence till B.C. 476, when it was taken by Hiero I., who removed its inhabitants to Leontini, and repeopled the city with a new colony of 5000 Syracusans and an equal number of Peloponnesians, at the same time changing its name to Ætna. Soon after the death of Hiero the former inhabitants obtained possession of the town, when it again took the name of Catana. In B.C. 403 it was taken by Dionysius of Syracuse, who, after plundering the city and selling the inhabitants for slaves, established there a body of Campanian mercenaries. In the first Punic war it was one of the first among the cities of Sicily that submitted to the Romans, and appears to have afterwards continued on friendly terms with them. In Cicero's time it was a flourishing and wealthy city; but it suffered so severely from the ravages of Sextus Pompeius, that afterwards Augustus sent a colony of veterans thither. It has frequently suffered from earthquakes and eruptions of Mount Ætna. It was almost totally destroyed by an earthquake in 1693, but was rebuilt in a more magnificent style, and is now considered the handsomest town in Sicily. The remains of the ancient city are numerous, and include a large theatre, an amphitheatre, a small theatre, ruins of baths, some massive sepulchral monuments, and fragments of an aqueduct, all of Roman construction, the Greek city having probably been destroyed by some of the earthquakes to which it has in all ages been subject. The streets are wide, regular, and paved with lava; of which also the public buildings are mostly built, with facings of limestone and ornamented with marble. The appearance of the city from the sea is magnificent, and the harbour is sheltered by a natural mole of lava. Among the principal public buildings are the magnificent cathedral rebuilt since the earthquake of 1693, the senate house, *monte di pieta*, theatre, and the vast Benedictine abbey. It has numerous churches, convents, hospitals and other charitable institutions, and a museum. The university, founded in 1445, is well attended, and has a good library and museums. Silk is largely manufactured, and with lava and amber articles constitutes its chief products. The harbour is small, being accessible only to small craft; by means of which, however, a considerable trade is carried on—principally in corn, macaroni, potatoes, olives, figs, silk, and wine.

CATANZARO, a city of Naples, capital of the province of Calabria Ultra II., stands on the slope of a lofty and rocky hill near the Gulf of Squillace, 30 miles S.S.E. of Cosenza. It is the seat of a bishopric, and has a cathedral, several churches and convents, a castle, royal academy of sciences, diocesan school, college, theatre, a foundling and two other hospitals, and other charitable institutions. It has manufactures of silk, velvet, and woollen goods, and a considerable trade in corn, wine, &c. Pop. 12,000. In 1783, many of its principal buildings were destroyed by an earthquake.

CATAPHRACT (Lat. *cataphractus*, mailed), a horseman in complete armour. The cataphracti of ancient times were heavy-armed cavalry, whose horses were defended with armour composed of plates of brass or other metal, or with scale armour. The weight of such armour frequently rendered them so unwieldy that when once on the ground both rider and horse became an easy prey to the enemy. Cataphracti, from very early times, were common under the name of *clibanarii* among the Persians, and were also employed in many other eastern nations; and their use was afterwards adopted by the Macedonians. Cataphracti were first employed in the Roman army by Constantine. Liv.

xxxv. xxxvii.; Amm. Marc. xvi.) Ships called *cataphractæ naves* were decked vessels similarly protected, in which the rowers sat below the deck, so as to be completely sheltered from the weapons of the enemy.

CATAPULTA, a military engine used by the ancient Greeks and Romans for discharging arrows, lances, and stones. In accounts of ancient sieges and other military operations, this word frequently occurs in conjunction with *ballista;* and under that head it will be seen that the two were frequently confounded by writers subsequent to the time of Julius Cæsar. The chief use of the catapult appears to have been to shoot the enemy when they appeared on the walls during a siege; the ballista being employed to discharge stones against the battlements, while the force of the *aries* or battering-ram was directed against the solid walls. Catapults were distinguished, as were also the ballistæ, into greater and less, but were of a long form, whereas the ballistæ were square. Their construction, however, must be a matter of conjecture, though it is probable that the principle of their projectile force differed little from that of the ballista. Dr Adam remarks in his *Antiquities,* that the most powerful of the catapultæ, ballistæ, and scorpiones, may be regarded "as gigantic cross-bows, consisting not of a single beam or spring but of two distinct beams, each of which was inserted into an upright coil of ropes tightly twisted in such a manner that the extremities of the arms could not be drawn towards each other without increasing the tension of the ropes so as to produce a most violent recoil." Some of the spears and darts thrown by the catapults are said to have been 18 feet long, and to have been projected with such velocity as to take fire in their course. This, of course, is absurd; but it is not improbable that spears with firebrands attached to them were sometimes projected from these engines.

CATARACT, a great fall of water over a precipice, as that of Niagara, the Rhine, Danube, and Nile. The fall of the Nile now known as Chellat, was called by the ancients *Catadupa. Cataracta* also denoted a portcullis, from the noise it makes in falling.

Cataract, a disease of the eye, in which the crystalline lens, or its capsule, becomes opaque, whereby vision is impaired or destroyed. The surgical operation of depressing a cataract is termed *couching.*

CATARRH (Latin *catarrhus*), a defluxion or increased secretion of mucus from the membrane which lines the nose, fauces, and bronchiæ, accompanied with feverishness, sneezing, cough, thirst, lassitude, and loss of appetite; and frequently an entire deprivation of the sense of taste. It is also called *coryza,* and in familiar language *a cold.* When epidemic, it is termed *influenza.* Catarrh is sometimes a chronic disease affecting the mucous membrane of the nose and fauces.

CATASTROPHE, the change or revolution which produces the final event of a dramatic piece; or the unfolding and winding up of the plot. The ancient drama was divided into the protăsis, epităsis, catastăsis, and catastrophe.

CATCH, or Round, in *Music,* a vocal composition in three or more parts, all written in the same clef, the performers of which sing each part in succession, as indicated by the figures at the beginning and end of each line, viz., the first voice sings the first, second, and third parts in succession, and then the first again, and so on. The second voice begins the first part when the first voice begins the second part. The third voice begins the first part when the second voice begins the second part, and the first voice the third part.

Catch-Word, among printers, the word placed at the bottom of each page, which is to be inserted as the first word on the following page. This system is no longer in use.

CATEAU, Le, or Cateau-Cambresis, a town of France, in the department of Nord, on the Selle, 15 miles E.S.E. of Cambray. It is well built, and was formerly fortified. Its chief manufactures are shawls, merinos, calicoes, lace, leather, soap, starch, and tobacco. In 1559, a treaty between France and Spain was concluded here. Pop. 7600.

CATECHESIS, instruction in the first rudiments of an art or science. In the ancient church catechesis was instruction given *viva voce,* either to children or adult heathens, preparatory to baptism. See Catechumen.

CATECHISM, a form of instruction by means of questions and answers, particularly in the principles of religion. The word is formed from κατηχέω, a compound of κατα and ἦχος, q.d. *circumsono,* alluding to the noise made in this sort of exercise. Anciently the candidates for baptism were only instructed in the secrets of their religion by tradition, *viva voce,* without writing; as had also been the case among the Egyptian priests, and the British and Gaulish druids, who thus communicated the mysteries of their theology.

Catechism is now generally used to denote an elementary book in which the principles of religion are summarily delivered by means of questions and answers.

CATECHIST, one who catechises or instructs novices in the principles of religion. Catechist also denotes a person appointed by the church to instruct those intended for baptism in the fundamental articles of the Christian faith.

CATECHU, Cutch, Terra-Japonica, or Gambeer, is an astringent extract prepared from the wood of the *Acacia Catechu,* from the kernels of the *Areca Catechu* or betel-nut palm, from the leaves of the *Uncaria Gambir,* and probably also from other plants. The wood, kernels, or leaves, as the case may be, are boiled in water till their substance is extracted; the decoction is then strained, and the boiling continued till it becomes sufficiently concentrated to form a tough extract on cooling. It is then moulded or made up into the various forms met with in commerce, and dried in the shade. Catechu is imported into Britain from Bombay, Calcutta, Singapore, Colombo, and Pegu, and the number of its varieties is great. The most valuable variety now brought to the market is known in commerce by the name of cutch (from its native name *cutt*), and is chiefly imported from Pegu. It is darker and more astringent than the ordinary catechues, and before the Burmese war used to sell from L.7 to L.8 a ton higher than they. In consequence of the deficient supply, its present price (1854) has reached L.50 a ton, the ton of the ordinary catechues being only L.30. All the other varieties of catechu at present in the market are known by the names of Terra-Japonica and Gambeer, the former having a dark-brown or reddish-brown fracture, the gambeers a yellow or gray fracture. Of the brown catechues, those known by the names of Ball and Lump Catechu, so named from the forms in which they are made up, are prepared from the inspissated juice of the Acacia catechu, and are the varieties most common in the British market. The Colombo catechu, often erroneously termed Columbia catechu, is in flat circular cakes, and is probably the produce of the Areca or betel-nut. The varieties known by the name of gambeers are usually met with in the form of cubical cakes, about an inch in diameter, and are chiefly obtained from the decoction of the leaves of the *Uncaria Gambir.*

All the catechues are powerful astringents, and consist essentially of tannin, and a peculiar acid called the catechuic acid. The uses of catechu in the arts are numerous, and it is now substituted in many cases for oak bark in tanning leather, steeping herring-nets, &c. The commercial *cutch,* as containing the largest proportion of tannin, is preferred for these purposes. Within the last twenty years catechu is very largely used by the dyer, for cloths, silks, and calicoes. According to the different mordants and reagents used, it gives all shades of bronze, browns, brown-grays, reddish-olive grays, brownish-yellow, &c., and has almost quite superseded madder for giving a golder coffee-brown colour.

In medicine catechu is used as an astringent for arresting mucous and bloody discharges; and is hence employed in diarrhœa, dysentery, and in some cases of chronic catarrh. It is also highly useful in ulceration of the gums and throat, and especially in that relaxation and congestion of the throat and fauces to which public speakers and singers are liable. From the government returns, it appears that for the three years ending 5th January the following were the importations of terra-japonica and cutch.

	Terra-Japonica.	Cutch.
1852	4783 tons.	2436 tons.
1853	3244 ...	2236 ...
1854	3904 ..	485 ...

CATECHUMEN, a candidate for baptism, or one who is preparing himself for receiving that rite.

In the primitive church, the catechumens were the lowest order of Christians. They were the children of believing parents, or pagans not fully initiated in the principles of the Christian religion; and were admitted to this state by the imposition of hands and the sign of the cross.

They were of four degrees, viz., those instructed privately without the church, and denied for some time the privilege of entering it; the *audientes*, or those who were admitted to hear sermons and the Scriptures read in the church, but not allowed to partake of the prayers; the *genu-flectentes*, so called because they received imposition of hands kneeling; the *competentes et electi*, the immediate candidates for baptism, or such as were appointed to be baptized at the next approaching festival. These last, after examination, were exercised catechetically during twenty days, and were obliged to fast and confess: some days before baptism they went veiled, and it was customary to touch their ears, saying, *Ephatha*, be opened, as also to anoint their eyes with clay; these ceremonies being in imitation of our Saviour's practice, and intended to shadow out their condition both before and after their admission into the Christian church.

CATEGORICAL, in a general sense, is applied to those things ranged under a CATEGORY.

CATEGORICAL, absolute, positive, express, not relative, or hypothetical; as a *categorical* proposition, syllogism, or answer.

CATEGORY, in *Logic*, a series or order of all the predicates or attributes contained under any genus. The school philosophers distributed all the objects of our thoughts and ideas into *genera*, in Greek called *categories*, and in Latin *predicaments*.

CATENARIAN CURVE. See ARCH, FLUXIONS.

CATERPILLAR, the name of all winged insects when in their reptile or worm state. See ENTOMOLOGY.

CATHARINA SANTA. See SANTA CATHARINA.

CATHARINE. *Knights of St CATHARINE of Mount Sinai*, an ancient military order, instituted for the protection of pilgrims going to pay their devotion to the body of St Catharine, a virgin of Alexandria distinguished for her learning, who is said to have suffered martyrdom under Maximin. The body of the martyr was discovered on Mount Sinai; and an order of knighthood was instituted in 1063, the members of which bound themselves by oath to guard the body of the saint, keep the roads secure, observe the rule of St Basil, and obey their grand-master. Their habit was white, and on it were represented the instruments of martyrdom by which the saint had suffered, namely, a half wheel armed with spikes, and traversed with a sword stained with blood.

ST CATHARINE *at Sienna*, *Fraternity of*, a religious and charitable society, instituted in that city in honour of St Catharine, a saint famous for her revelations, and for her supposed marriage with Jesus Christ, whose wedding-ring is preserved as a valuable relic.

CATHARTICS, medicines which promote alvine discharges; purgatives.

CAT-HEAD, a strong timber projecting from either bow of a ship, to which the anchor is raised and secured.

CATHEDRA (Latin *cathĕdra*, from κατα and ἕδρα, a seat); a chair; more particularly used to denote a professor's chair or a preacher's pulpit; and also used for a bishop's see, or throne in a church.

CATHEDRAL, the principal church in a diocese; so called from possessing the episcopal chair or throne. The term cathedra (from which cathedral is derived) was originally applied to the seats in which the bishops and presbyters sate in their assemblies, which originally were held in the rooms where the worship of the early Christians was conducted. In after times the choir of the cathedral was made to terminate in a semi-circular or polygonal apsis; and in the centre of this recess was placed the chair or throne of the bishop, as president, while seats of an inferior class for presbyters were ranged on either side. The episcopal authority did not reside in the bishop alone, but in the presbyterium as a body. Till the time of Constantine the Christians were not permitted to erect temples; and hence by *churches* they meant only to denote their assemblies, and by *cathedrals* their consistories.—(See Bingham's *Origines Ecclesiasticæ, or Antiquities of the Christian Church.*)

CATHERINE PARR, *Queen of England*. See PARR.

CATHERINE I., *Empress of Russia*, was the natural daughter of a country girl, and was born at Ringen, a small village upon the Lake Virtcherve, near Dorpt in Livonia, in 1687. Her original name was Martha, which she changed for Catherine. Count Rosen, who owned the village of Ringen, supported both the mother and the child, and was for that reason supposed to have been the father. When only three years old, by the death of her mother and Count Rosen she was left in so destitute a situation that the parish-clerk of the village received her into his house. Soon afterwards Gluck, Lutheran minister of Marienburg, took her under his protection, and employed her in attending his children. In 1701, when she had attained the fourteenth year of her age, the romance of her life began with her espousal to a dragoon of the Swedish garrison of Marienburg. According to one account, the bride and bridegroom remained together eight days after marriage; and another asserts that on the morning of the nuptials her husband was sent with a detachment to Riga, and the marriage was never consummated. This much is certain, that the dragoon was absent from Marienburg when it surrendered to the Russians, and Catherine, who was reserved for a higher destiny, never saw him more.

Upon the taking of Marienburg, General Bauer saw Catherine among the prisoners, and took her to his house, where she superintended his domestic affairs, and was supposed to be his mistress. From his house she passed into the family of Prince Menzikof, who was no less struck with the attractions of the fair captive. With him she lived until 1704; when, in the seventeenth year of her age, she became the mistress of Peter the Great, whose affections she succeeded so completely in gaining that he married her on the 29th of May 1711. The ceremony was secretly performed at Yaverhof, in Poland, in the presence of General Bruce; and on the 20th of February 1712 was solemnized with great pomp at Petersburg.

Peter expired on the 28th of January 1725. Immediately after his death, the senate and nobility assembled to proclaim his successor, and the address of Menzikof and his party, who had gained over the imperial guards and provided witnesses of Peter's expressed intentions in regard to Catherine, overcame the hesitation of some of the nobles and softened the hostility of others so as to procure the appointment of his former housekeeper on the spot. The matter having been thus successfully managed in the assembly, she next presented herself at the window to the guards and the people, who shouted "Long live

Catherine!" whilst Menzikof scattered among them handfuls of money. Thus, says a contemporary, the empress was raised to the throne by the guards, in the same manner as the Roman emperors were by the prætorian cohorts, without either the appointment of the people or of the legions.

The reign of Catherine may be considered as the reign of Menzikof; for that empress having neither inclination nor abilities to direct the helm of government, placed the most implicit confidence in a man who had been the original author of her good fortune, and the sole instrument of her elevation to the throne. During her short reign her life was exceedingly irregular; she was extremely averse to business; would frequently, when the weather was fine, pass whole nights in the open air; and was particularly intemperate in the use of tokay. These irregularities, joined to a cancer and a dropsy, hastened her end; and she expired on the 17th of May 1727, a little more than two years after her accession to the throne, and in about the fortieth year of her age.

Catherine II. Empress of Russia, whose original name was Sophia Augusta Frederica, was the daughter of Christian Augustus of Anhalt Zerbst, a small district in Upper Saxony, and was born in the castle of Zerbst on the 23d of May 1729. She was educated under the eye of her parents, along with her brother Prince Frederic Augustus, and at an early period displayed a masculine spirit. Her person was at once majestic and handsome, her complexion clear and bright, and the expression of her countenance dignified, yet tempered by a smile of beneficence. But it was early observed that under this exterior she concealed a certain austerity of disposition, and an ambition, which was even then considered as excessive, and which proved afterwards insatiable.

The Empress Elizabeth, who had pitched upon her nephew the duke of Holstein Gottorp Oldenburg as her successor, was also desirous to choose a consort for him, and the princess of Anhalt Zerbst was selected upon this occasion, when only fourteen years of age. She was chiefly indebted for this unexpected honour to the tender regard which her imperial majesty always entertained for the memory of the princess's uncle, who had been her lover; and in an evil hour she united the fate of the prince, better known afterwards by the name of Peter III. to that of the princess of Anhalt Zerbst. In consequence of a special invitation, the future empress repaired to St Petersburg, accompanied by her mother, and being admitted into the bosom of the Greek church, the ceremonial of marriage, after some delay, took place; upon which these august personages were formally acknowledged, by her imperial majesty and the senate, as Grand Duke and Duchess of Russia.

The empress hoped that the name and pretensions of Prince Iwan would be obliterated by the issue of the grand duke; and the whole empire impatiently wished for and now expected an heir to the throne of Peter the Great. But a marriage of eight years was not productive of any issue; and strange suspicions began to be entertained. This alarmed the court; for a formidable rival, who possessed a superior claim to the throne, still existed; and although he was in bondage, yet, in a country like Russia, the interval is sometimes small between a dungeon and a throne. But the birth of a son and a daughter, soon afterwards, put an end to all apprehensions of this kind, and tended not a little to give stability to the empire.

The grand duke, who at times discovered noble and even magnanimous sentiments, had about this period formed a most unfortunate connection with Elizabeth Voronsoff, a lady of high rank, but celebrated neither for her beauty nor for her talents. He seldom saw his consort in private, and all the hours which were not occupied either by military exhibitions or the pleasures of the table were entirely devoted to his mistress.

The grand duchess, on the other hand, is said to have spent much of her time in company with a young Pole, whose history, like that of Catherine's, has since been interwoven with the annals of Europe. This was Count Poniatowski, afterwards known as Stanislaus Augustus, king of Poland. He was the third son of a grandee of the same name, the favourite of Charles XII. of Sweden, by the Princess Ezatoryska, who boasted the possession of the noblest blood in Poland, as she traced her descent from the Jagellons, the ancient sovereigns of Lithuania. His person was of exquisite symmetry, his air was noble, his manners were agreeable, and his mind, a circumstance extremely rare, was not less graceful than his person. At this period he was in no higher station than that of a gentleman in the suite of the minister plenipotentiary from England, who had formed an intimacy with his family during a former mission at Warsaw. But being now taught to look higher, he returned to his native country, and appeared soon afterwards at Petersburg as ambassador from the king of Poland. In this new capacity he did not forget to pay his respects at the little court of Oranienbaum; and the young plenipotentiary, with a view of ingratiating himself with the grand duke, smoked, drank, and praised the king of Prussia. At length Paul Petrowitsch received the Polish minister with coolness, and he was actually forbidden to visit at the palace. This, however, it is said, did not deter him from concealing the order of the white eagle, and disguising himself as a mechanic, under which assumed character he repaired one summer evening to the gardens in the neighbourhood of the Gulf of Cronstadt; but he was discovered by his highness, who ordered him to be brought before him, and, after affecting to reprimand the captain of his guard for his disrespect to the representative of a crowned head, told him he was at liberty to depart.

From this moment the grand duchess is said to have changed both her system and her conduct. She had formerly aspired only to direct the counsels of the future emperor; she now resolved, if possible, to obtain the crown for her son, and the regency for herself. Such a task would have discouraged a common mind; for it was impossible to achieve it without prevailing on the empress to consent to dethrone her own nephew. But Bestuchef, the grand chancellor, who hated the heir apparent, joined cordially in the scheme; and Elizabeth, who had herself obtained the crown by means of a revolution, was taught to tremble for her life, in consequence of the designs of her successor, who was represented as having resolved to shorten her days by poison. An unexpected revolution in the ministry, however, put an end to these intrigues. Bestuchef was driven into exile, and Poniatowski was recalled.

A long and melancholy interval now ensued, during which the ambition of the grand duchess was rather suspended than annihilated. In the midst of the gloom which overspread her, however, she had recourse to, and soothed her anguish by means of, books; and it was in her closet that she laid the foundation of her future greatness, and rendered herself in some measure deserving of a throne. During her leisure moments she found means to gain partisans; and she acquired the favour of the soldiery, who did duty around her person, by means of her liberality and condescension. Peter, on the other hand, to the personal exertions of a common soldier added the orgies of a bacchanalian. Surrounded by his male and female favourites, he consumed whole days and nights in intoxication, and forgot that he was a prince. There were some few moments, however, when he appeared great, and even mag-

nanimous; but unhappily these were of short duration; and it was his misfortune to have a weak woman for his mistress, and an able and ambitious one for his wife.

Such was the situation of the court when Elizabeth died, on the 5th of January 1762. The grand duke now ascended the throne by the name of Peter III. The following answer to a letter from the king of Prussia, who had requested him to be on his guard against the plot which was then hatching, conveys no unfavourable opinion of his heart: "Touching the interest you express for my safety, I request you will rest contented. I am called the father of my soldiers; they prefer a male to a female government. I walk alone constantly in St Petersburg: if any mischief is meditated, it would have been effected long since; but I am a general benefactor. I repose myself on the protection of heaven; trusting to that, I have nothing to fear."

This false security proved his ruin. Whilst his mind was occupied with plans of reform, and he aspired to rival, nay even to excel, his illustrious predecessor, whose name he had assumed, a person who had sworn fidelity to him at the altar, and who owed him allegiance by the double ties of wife and subject, was actually employed in planning a conspiracy, and organizing a revolt against him. It has been said that he intended to have shut up his consort and son in a convent. But it is known that, so far from this being the intention of Peter, he was preparing for a journey to Holstein, and had actually empowered his consort to act as regent during his absence.

The mistakes of the emperor did not escape the penetration of his enemies. He purposed to carry his guards into Holstein, with a view to recover the possessions wrested from his ancestors. But the regiments which had hitherto done duty at the palace, and were inured to the indulgences of the capital, revolted at the idea of a foreign war; they had been accustomed to be governed by women, and they were taught to fix their eyes on the consort of the czar.

It is not the least wonderful part of her conduct, that previously to the great catastrophe now meditating, Catherine had contrived to appear abandoned by all the world. She knew how interesting a female, and more especially an empress, appeared whilst in distress; and she took care to heighten the sensibility of the public, by bursting at times into a flood of tears. This artful woman had found means to attach many persons to her destiny; it must be owned, however, that her adherents were neither so powerful nor so numerous as to afford her any well-founded hopes of success. She had gained several subalterns, and some privates, of the guards; but her principal partizans consisted of the Princess D'Aschekof, niece to the new chancellor; Prince Rozamouski, who had risen from obscurity, having been originally a peasant; Odart, an intrigueing Italian; and Panin, governor to the grand duke. The arrest of Passick, one of the conspirators, seemed to lead to a discovery which would have proved fatal to the malcontents; but this very circumstance induced them to declare instantly, and in the end crowned an apparently desperate attempt with complete success.

The empress, who was asleep at the castle of Peterhof, received intimation of their design by a common soldier, who soon afterwards returned with a carriage and eight horses. On the faith of this man, and accompanied only by a few peasants, a German female domestic, and a French valet-de-chambre, she arrived at eight o'clock in the morning in the capital, and stopped opposite the barracks of the regiment of Ismailof. There she addressed the soldiers in an eloquent speech, intermingled with sighs and tears, and actually found means to persuade them that she and her son had but that moment escaped from the hands of assassins, sent by the emperor to murder them. This story, by agitating the passions of the troops, had a wonderful effect on them; and they all swore, with the exception of only one regiment, to die in defence of her and the young archduke. Upon this the empress ordered a crucifix to be brought, and commanded the priests to administer a new oath of allegiance. She afterwards repaired to one of the principal churches, where she was met by the Bishop of Novogorod and the clergy, and, having returned thanks to Almighty God, ascended a balcony, and presented her son to the people. In a few hours she was again seen, dressed in the uniform of the guards, riding at the head of a numerous and well-appointed army against her husband.

On the first intelligence of the plot, Munich had repaired to his benefactor, and advised him to march directly to the capital, at the head of his German troops. "I shall precede you," said the generous veteran, "and my dead body shall be a rampart to your sacred person." But, on the other hand, the emissaries of the empress, bathing his hands with their hypocritical tears, deprecated resistance, magnified the danger, and invited him to repose in the inviolable fidelity of his consort. In short, on the 14th of July 1762, he was taken prisoner by the orders of his own wife, to whom he had been married fourteen years; prevailed on by the threats and intreaties of Count Panin to renounce his crown; conveyed to the castle of Robscha; and, three days afterwards, put to death. The empress, on her assumption of the crown, now rendered vacant by murder, notified the event to all the courts of Europe, under her new name of Catherine Alexiewna II. But there was still a competitor for the empire; and suspicion never slumbers near a throne. This was Prince Iwan, son of the princess of Mecklenburg, and grand nephew of Peter the Great and the empress Anna Iwanowna, who had destined him as her successor; but in consequence of a former revolution, he had been seized while yet an infant, and doomed to lead a life of captivity. During eighteen years of precarious existence, he had been shut up in the castle of Schlusselburg, and never in all that time had he breathed the open air, or beheld the sky, but once. This prince was visited by Peter III., who, finding him in an arched room twenty feet square, determined to set him at liberty; but his generous intentions were unavailing; the youth, in consequence of his long and solitary confinement, had been deprived of his senses. In this situation the emperor determined to build a house for him, with a convenient terrace, where he might take the air daily within the fortress. Such, however, are the changes of fortune, that, in three weeks, Peter himself was precipitated from a throne, and suffered a violent death. This event was but the prelude to that of Iwan; for, as orders had been given, in case of an attempt to rescue him, that an end should be put to his life, and as a real or pretended plot had been hatched for this purpose, the motives and details of which have hitherto been involved in the most profound obscurity, the unhappy prince experienced the same fate as his generous protector.

Catherine being now firmly seated on the throne, wisely determined to divert the thoughts of the nation from the late horrid scenes, and fix them upon more agreeable objects. Having soothed Prussia, acquired a preponderance in the cabinet of Denmark, which had for some time been an absolute monarchy, and entered into a league with the popular party in Sweden, not yet bereft of its liberties; she cast her eyes on Courland, then governed by Prince Charles of Saxony, the second son of Augustus III. king of Poland, and, finding that country admirably situated for the increase of her present and the extension of her future power, she, in 1762, expelled the lawful sovereign, and in-

Catherine. vested Biron, a creatute of her own, with the ducal cap. Nor was she content with this; for the new duke, soon reduced to the most abject dependence, was prevented from resigning his precarious power, and the states assembled at Mittau were actually interdicted from nominating a successor. This, however, was only a prelude to scenes of greater importance; for she had scarcely dethroned one sovereign before she undertook to create another. Augustus II., or, as he is called by some, Augustus III. of Poland, having died at Dresden in 1763, her imperial majesty did not let slip so favourable an opportunity for interfering in the appointment to the vacant throne, and even placing upon it one of her own dependents. Count Poniatowski, on the elevation of Catherine, had sent a friend to Petersburg to sound the disposition of the empress about his return to that capital, where he naturally hoped to participate in her power, and bask in the sunshine of the imperial smiles. But the more prudent German, who was at this very moment meditating a splendid provision for him elsewhere, prohibited the journey from political motives. Accordingly, notwithstanding the opposition of the grand chancellor Bestuchef, and indeed of all her ministers, she determined to invest him with the ensigns of royalty. The head of the house of Brandenburg, being swayed by his hatred to Saxony and Austria; or, what is still more likely, the Prussian eagle having perhaps, even now, scented his future prey; Catherine was enabled to send into Poland 10,000 men, who, encamping on the banks of the Vistula, overawed the deliberations of the diet, assembled on the 9th of May 1764, and placed Stanislaus Augustus on the throne.

Having thus conferred the crown of Poland on an amiable and accomplished prince, who, on account of his youth, his poverty, and even his dependence on Russia, would have been excluded from that painful pre-eminence had the free suffrages of the nation been collected, and who, in consequence of the hatred of his countrymen, was still more subjected to the dominion of the empress, she began to prepare for a war against the Turks, which was accordingly declared in 1768. During this contest the Greek cross was triumphant both by sea and land.

In the mean time a dangerous insurrection broke out in the very heart of her dominions, instigated by a Cossack of the name of Pugatschef, who pretended to be Peter III. After displaying great valour and considerable talents, which had enabled him, at the head of raw and undisciplined levies, to contend against veteran troops and experienced generals, this unfortunate man was at length seized, inclosed in an iron cage, and beheaded at Moscow on the 21st of July 1775.

On the 21st of July in the preceding year, a peace had been concluded with the porte, which proved highly honourable to Russia; but it was productive of little benefit to the latter; for the liberty of navigating the Black Sea, and a free trade with all the ports of the Turkish empire, which would have afforded inestimable advantages to a civilized people, proved of but little consequence to a nation unacquainted alike with commerce and manufactures.

Accordingly, we find her imperial majesty still unsatisfied. Scarcely had four years elapsed, when, after an armed negociation, a new treaty of pacification was agreed to by the reluctant sultan, on the 21st of March 1789, by which the Crimea was declared independent; an event not calculated to allay ancient jealousies, but, on the contrary, to produce fresh dissensions, as it afforded an opening into the very heart of the Turkish empire, and a ready pretext for future interference. New claims and new concessions immediately followed. Russia insisted on establishing consuls in the three provinces of Moldavia, Wallachia, and Bessarabia; which she was accordingly permitted to do by the treaty of 1781. But mortifying as this compliance was, it produced only a short respite. The emperor Joseph was now brought upon the political stage, and the Roman and Russian eagles, after hovering over the carcass of the Turkish empire, and meditating to devour the whole, were at last content with part of the prey. The empress, as it may be readily believed, was not inattentive to her own interests; and by the treaty of Constantinople, signed on the 9th of January 1784, the entire sovereignty of the Crimea, which then received its ancient name of Taurica, the isle of Taman, and part of Cuban, were ceded to Russia. Catherine.

Thus, in the fifty-eighth year of her age, and the twenty-fifth of her reign, Catherine may be said to have attained the very summit of her wishes. Knowing the effect of splendour upon ignorance, she ushered in the year 1787 with a brilliant journey to Cherson. Accompanied thither at once by a court and an army, with foreign ambassadors, an emperor and a king, in her train, she intended to have assumed the high-sounding titles of Empress of the East, and Liberator of Greece. At Kiow, where she remained during three months, she was received under triumphal arches; and, having heard the petitions of the deputies from distant nations, and extended the walls of that city, she inscribed in Greek characters, on the quarter next to Constantinople, "Through this gate lies the road to Byzantium."

Scarcely, however, had the empress, after visiting Moscow, returned to her capital, when the Porte thought proper to declare war. Her majesty, long prepared for an event which was far from being displeasing, called forth the stipulated succours of her ally the emperor; and the combined army under the Prince de Cobourg made itself master of Choczin after a siege of three months. Oczakow, after a still more obstinate resistance, was assaulted and taken by the Russians alone. Having concluded a final treaty of peace with the Turk on the 9th of January 1792, by which the river Dniester became the boundary of the two empires, and was to be navigated by both, the empress had more time to apply her mind to European politics. Part of Poland had been dismembered and partitioned during the year 1792; not only in contravention of the unalienable rights of nations, but in direct opposition to the most solemn treaties on the part of Russia, Prussia, and Austria. The revolution which took place in that ill-fated country on the 3d of May 1791, and which afforded the prospect of a happy and stable government to the remains of the republic, was the signal of its annihilation. The imperial and royal spoilers seized this opportunity to fall once more in concert on their prey, which was in no condition to resist this detestable confederacy; and they shared it at their pleasure. Another great object had for some time engaged the attention of Catherine. This was the French revolution. With a treasury nearly exhausted by the war with the Ottoman porte, which had not then terminated, and at a distance from the scene of action, the empress could not well engage in the contest; but she readily entered into the coalition, and soon afterwards subsidized the king of Sweden. She also launched forth a menacing manifesto against France, and prepared for a new war. Afterwards, at the instigation of Zuboff, she formed the design of giving effectual assistance to the confederated kings; and, as a proof of her intentions, issued orders for a squadron of men-of-war to join the English fleet, and commanded a levy of 60,000 troops. But she at the same time prosecuted a war on the frontiers of Persia, where her army, under the command of a near relation of the grand master of the artillery, had experienced

a most humiliating defeat; and she was now preparing to send fresh succours to his assistance.

But while the mind of Catherine was occupied with projects for the overthrow of the French republic, and the subjugation of the distant Persians, she was smitten by the hand of death On the morning of the 9th of November she rose at her usual hour, and breakfasted, according to custom, on coffee. Some time afterwards she retired to her closet; and her long absence exciting the suspicion of her attendants, they entered the apartment and found her lying speechless. Dr Rogerson, her physician, being sent for, treated her disease as apoplexy, and considerable relief seemed to ensue after the application of the lancet. But the empress never entirely recovered her senses, and did not utter a single word during the remainder of her life, which was prolonged till ten o'clock in the evening of the 10th of November 1797.

Catherine was the only sovereign of Russia who ever exhibited a taste for letters. Nor was this all. She was an author herself, and did not disdain to compose little treatises for her grandchildren, whose education she superintended. She also possessed an exquisite relish for music, and brought Gabrielli and a number of singers of great note from Italy, allowing them liberal salaries, and treating them with great attention. Throughout the whole of her long reign Catherine also evinced a marked predilection for painting. In the midst of a war with the Turks she purchased pictures in Holland to the amount of 60,000 rubles, all of which were lost by the ship which carried them being wrecked on the coast of Finland. This, however, served rather to stimulate her to fresh exertions, and her agents accordingly procured whatever was to be found in Italy worthy of notice. The Houghton collection from England was also transferred, by an act of her munificence, to the shores of the Baltic; and, whilst it added to her glory, lowered this nation in the eyes of foreigners. Her conduct to learned men was truly worthy of a woman of genius. She was proud of the correspondence and friendship of Voltaire; she invited Diderot to her court, and lived with him while there in habits of the utmost familiarity; to D'Alembert she looked up as to a superior being, and endeavoured, although in vain, to induce him to fix his residence at St Petersburg. Her political character has been variously estimated; and no sovereign of modern times has attracted a greater share of censure and eulogium than Catherine. As a female she appears at times the slave of lust and the puppet of her courtiers; as a sovereign we behold her towering like an immense colossus, with one foot placed on Cherson, and another on Kamtschatka, waving her iron sceptre over the subject nations, and regulating the destiny of a large portion of mankind. The world, however, shudders at the untimely fate of Peter and of Iwan, and posterity will not easily pardon the partition of Poland and the massacres of Ismailof and of Praga.

Catherine, *St, Order of*, appropriated to ladies only, was instituted in 1714, by Catherine, wife of Peter the Great, in memory of his signal escape from the Turks in 1711. Its emblems are a red cross supported by a figure of St Catherine, and fastened to a scarlet string edged with silver, inscribed with the name of St Catherine and the motto *Pro fide et patria*.

CATHETER, in *Surgery*, a tube, usually of silver, which may be introduced by the urethra into the bladder, to draw off the urine when the natural discharge is suppressed.

CATHETUS, in *Geometry*, a line or radius falling perpendicularly on another line or surface; as the two sides of a right-angled triangle.

Cathetus *of Incidence*, in *Catoptrics*, a right line drawn from a point of the object, perpendicular to the reflecting line.

Cathetus *of Reflection*, or *of the Eye*, a right line drawn from the eye, perpendicular to the reflecting plane.

Cathetus *of Obliquation*, a right line drawn perpendicular to the speculum, in the point of incidence or reflection.

Cathetus, in *Architecture*, a vertical line supposed to pass through the centre of a cylindrical body.

CATHOLIC, universal or general; also liberal, not bigoted.

Catholic *Church*. The rise of heresies induced the primitive Christian church to assume the appellation of *catholic*, to distinguish itself from all sects, who, though they had party names, sometimes sheltered themselves under the name of Christians.

This epithet is now appropriated by the Romish Church; but strictly, there is no Catholic church, there being no universal Christian communion.

Catholic *King*, a title which has long been hereditary to the king of Spain.

CATILINA, Lucius Sergius, a Roman of a noble family, who, after ruining his fortune by debauchery and excesses of every kind, formed the design of destroying the senate, assassinating the consuls, seizing the public treasury, setting fire to Rome, and usurping sovereign power. In order to prosecute this design, Catiline associated in his plot some young noblemen, whom he prevailed upon, it is said, to drink human blood as a pledge of their union. His conspiracy, however, was discovered by the vigilance of Cicero, who was consul at the time; upon which Catiline retired from Rome, and having raised an army, fought with the utmost valour against Petreius, lieutenant to Antony, Cicero's colleague in the consulship. In this battle Catiline was defeated and killed, B.C. 62. The history of Catiline's conspiracy has been written by Sallust. See Roman History.

CATMANDOO, or Khatmandu, a city of Northern Hindustan, capital of the Nepaul country, and the residence of the Goorkhali rajah. It is situated in a romantic valley of Nepaul proper, on the E. bank of the Bishenmutty river, 40 miles S. of the Himalaya Mountains, and about 150 N. of the British possessions. It extends about a mile along the river, and is at its greatest breadth about half a mile; but in general it does not exceed a quarter of a mile. The houses, which are of two, three, and four stories, are of brick, with pent roofs, and have a mean appearance. The streets are narrow and filthy, as in other eastern towns. The temples are almost as numerous as the houses. The greater part are of wood, but several are brick and stone. The Brahminica religion is professed in all these. It possesses an ancient temple dedicated to Boodh, which is highly celebrated among the Tartars, and a great resort of pilgrims. It is built of stone, and consists of three lofty pyramids with two square apartments. It is of great antiquity, having been erected when Nepaul was in possession of the Thibetians. The possession of this temple has been always claimed by the sovereign pontiff, the Dalui Lama, on the ground of its having been in the possession of his predecessors from time immemorial; but in consequence of disputes the Lama's vicar was obliged to retire, and it is now held by a legate of the ruler of Bootan, who is a Boodhist. The city has markets supplied with every convenience. and is estimated to contain 50,000 inhabitants. Long. 85 18. E., Lat. 27. 42. N.

CATO, Marcus Portius, the Censor, sometimes styled Cato Major, one of the greatest men among the ancients, was born at Tusculum in the year B.C. 234. He began to bear arms at seventeen, and on various occasions signalized himself by his valour and military abilities. He was a man of great sobriety, and reckoned no bodily exercise unworthy of him. He had but one horse for himself and his baggage, and he looked after and dressed it himself. On his return from his campaigns he betook himself to plough his farm;

not that he was without slaves to do it, but because such was his inclination. He also dressed like his slaves, sat at the same table with them, and partook of the same fare. He did not in the meanwhile neglect to cultivate his mind, especially in regard to the art of speaking; and he employed his talents, which were of a very high order, in generously pleading causes in the neighbouring cities without fee or reward. Encouraged by Valerius Flaccus, a young nobleman who had a country seat in the neighbourhood, Cato went to Rome, where, not less by his own merits than by the influence of his patron, he soon attracted public notice. He was first elected tribune of the soldiers for the province of Sicily; and he was next made quæstor in Africa under Scipio. Having in this last office reproved the general for his profuseness to his soldiers, the latter answered that he would make war at what expense he pleased; nor was he to give an account to the Roman people of pelf, but of his enterprises, and the execution of them. Cato, provoked at this answer, left Sicily and returned to Rome.

In B.C. 198 he was made prætor, and fulfilled the duties of that office with the strictest justice. He conquered Sardinia, governed with admirable moderation, and in 195 was created consul. He carried on war in Spain with such success, that on his return he was honoured with a triumph. As tribune in the war of Syria, he gave distinguished proofs of his valour against Antiochus the Great, and contributed materially to the decisive victory at Thermopylæ. He now for the second time stood candidate for the office of censor. But the nobles, who not only hated him as a *new* man, but dreaded his severity, set up against him seven powerful competitors. Valerius Flaccus, who had introduced him into public life, and had been his colleague in the consulship, was a ninth candidate; and these two united their interests. On this occasion Cato, far from courting the favour of the people by insinuating speeches, or giving hopes of gentleness or complaisance in the execution of his office, loudly declared from the rostra, with a threatening look and voice, that the times required firm and vigorous magistrates to put a stop to that growing luxury which menaced the republic with ruin; censors who would cut up the evil by the roots, and restore the rigour of ancient discipline. It is to the honour of the Roman people that, notwithstanding these startling intimations, they preferred Cato to all his competitors who courted them by promises of a mild and easy administration. The comitia also appointed his friend Valerius his colleague, without whom he had declared that he could not hope to compass the reformations he proposed. Cato's merit, indeed, was superior to that of any of the great men who stood against him. He was temperate, brave, and indefatigable; frugal of the public money, and wholly incorruptible. There is scarcely any talent requisite for public or private life which he had not received from nature, or acquired by industry. He was a great soldier, an able statesman, an eloquent orator, a learned historian, and skilful in rural affairs. Yet with all these accomplishments he had very great faults. His ambition, being poisoned with envy, disturbed both his own peace and that of the whole city as long as he lived. Though he refused to take bribes, he was utterly unscrupulous in amassing wealth by all means which the law did not punish as criminal.

To the nobles and their wives, no part of the censor's conduct seemed so obnoxious as the taxes he laid upon luxury in all its branches, including dress, household furniture, women's toilets, chariots, slaves, and equipage. The people, however, were in general pleased with his regulations; insomuch that they ordered a statue to be erected to his honour in the Temple of Health, with an inscription which mentioned nothing of his victories or triumphs, but imported only, that by his wise ordinances in his censorship he had reformed the manners of the republic. Plutarch relates that before this, upon some of Cato's friends expressing their surprise that when many persons without merit or reputation had statues, he had none, he answered, "I had much rather it should be asked why the people have not erected a statue to Cato than why they have." Cato was the chief instigator of the third Punic war. Being despatched to Africa to terminate a difference between the Carthaginians and the king of Numidia, on his return to Rome he reported that Carthage had grown excessively rich and populous, and warmly exhorted the senate to destroy a city and republic during whose existence Rome could never be safe. Having brought from Africa some very large figs, he showed them to the conscript fathers in one of the lappets of his robe. "The country," says he, "where these figs grew, is but three days' voyage from Rome." We are told that from this time he never spoke in the senate upon any subject without concluding with these words, "Carthage must be destroyed." He judged that for a people enervated by prosperity nothing was more to be feared than a rival state, always powerful, and now, from its misfortunes, grown wise and circumspect. He held it necessary to remove all dangers that could be apprehended from without, when the republic had within so many distempers threatening her destruction.

Cato died in the year B.C. 149, aged eighty-five. He was twice married; first to Licinia, a lady of noble birth, who bore one son; and in his old age he espoused Salonia, the youthful daughter of his scribe and client M. Salonius, by whom in his eightieth year he had a son, who was the ancestor of Cato of Utica.

Of Cato's several works the most important was that entitled *Origines*, a history of Rome, of which only fragments are extant. His treatise on husbandry, *De Re Rustica*, has been preserved. The best editions of it are those contained in the *Scriptores Rei Rusticæ* of Gesner (Lips. 1773–4); and Schneider (Lips. 1794–7).

CATO, *Marcus Portius*, or *Cato of Utica*, was great-grandson to Cato the Censor. It is said that from his infancy he discovered, by his speech, his countenance, and even by his childish sports and recreations, an inflexibility of mind; for he forced himself to execute whatever he had undertaken, though the task was ill suited to his strength. He was equally rude to those who flattered and to those who menaced him; he was rarely seen to laugh, or even to smile, and not easily provoked to anger; but if once incensed he was scarcely to be pacified. Sylla, who had conceived a friendship for the father of Cato, sent often for him and his brother, and talked familiarly with them in presence of the boy. Cato, who was then about fourteen years of age, seeing on one occasion the heads of several persons brought in, and observing the suppressed agitation of those who were present, asked his preceptor "why does nobody kill this man?" "Because," said the other, "he is more feared than he is hated." The boy replied, "why then did you not give me a sword when you brought me hither, that I might have stabbed him and freed my country from this slavery?"

On the death of his father, under Antipater of Tyre, he applied more rigorously to the study of the Stoic philosophy, the principles of which so well suited the inflexibility of his character; and made considerable proficiency in declamation, which he regarded as a necessary means of defending the cause of justice. To increase his bodily strength, he inured himself to suffer the extremes of heat and cold; and used to make journeys on foot and bare-headed in all seasons. When he was sick, patience and abstinence were his only remedies; he shut himself up, and would see nobody till he became well. The only exception to his usual abstinence was made in favour of the philosophers, at whose entertainments it is said he acquired information at the expense of a habit of drinking freely, and sitting at table

till morning. He affected singularity; and, in things indifferent, sought to act directly contrary to the taste and fashions of the age. Magnanimity and constancy are generally ascribed to him; and Seneca makes that haughtiness and contempt for others which in Cato accompanied those virtues, a subject of praise. He served as a volunteer under Gellius Poplicola, in the war of Spartacus; and when military rewards were offered him by the commander he refused them, because he thought he had no right to them. Some years afterwards he went a legionary tribune into Macedonia under the pro-prætor Rubrius; in which station he appeared, in dress, and during a march, more like a private soldier than an officer: but the dignity of his manners, the elevation of his sentiments, and the superiority of his views, set him far above those who bore the titles of generals and pro-consuls.

Cato laboured to bring about a reconciliation between Cæsar and Pompey; but seeing that all his efforts were in vain he took part with the latter. When Pompey was slain he fled to Utica; and being pursued by Cæsar, advised his friends to go and throw themselves on the clemency of the conqueror. His son, however, remained with him; and also Statilius, a young man, remarkable for his hatred of Cæsar. The evening before the execution of the purpose he had formed with regard to himself, after bathing he supped with his friends and the magistrates of the city. They sat late at table, and the conversation was lively. The discourse falling upon this maxim of the Stoics, that the wise man alone is free and that the vicious are slaves, Demetrius, who was a Peripatetic, undertook to confute it from the maxims of his schools. Cato, in answer, treated the matter very amply, and with so much earnestness and vehemence of voice that he betrayed himself, and confirmed the suspicion of his friends that he designed to kill himself. When he had done speaking, a melancholy silence ensued; which was broken by Cato, who turned the discourse to the present situation of affairs, expressing his concern for those who had been obliged to put to sea, as well as for those who had determined to make their escape by land and had a dry and sandy desert to pass. After supper, the company being dismissed, he walked for some time with a few friends, and gave his orders to the officers of the guard; and going into his chamber he embraced his son and his friends with more than usual tenderness, which further confirmed the suspicions of the resolution he had taken. He then laid himself down on his bed, and took up Plato's Dialogue on the Immortality of the Soul. Having read for some time, he looked up, and missing his sword, which his son had removed while he was at supper, he called a slave and asked who had taken it away; and receiving an evasive reply he resumed his reading. Some time afterwards he asked again for his sword, and without showing any impatience ordered it to be brought to him; but having read out the book, and finding nobody had brought him his sword, he called for all his servants, upbraided them sternly, and struck one of them on the mouth with so much violence as to hurt his own hand, crying out in a passionate manner, "What! do my own son and family conspire to betray me and deliver me up naked and unarmed to the enemy?" Immediately his son and friends rushed into the room, and began to lament, and to beseech him to change his resolution. Cato raising himself, and looking fiercely at them, "How long is it," said he, "since I have lost my senses, and my son is become my keeper? Brave and generous son, why do you not bind your father's hands, that when Cæsar comes he may find me unable to defend myself? Do you imagine that without a sword I cannot end my life? Cannot I destroy myself by holding my breath for some moments, or by striking my head against the wall?" His son answered with his tears, and retired. Apollonides and Demetrius remained with him; and to them he addressed himself in the following words: "Is it to watch over me that ye sit silent here? Do you pretend to force a man of my years to live? or can you bring any reason to prove that it is not base and unworthy of Cato to beg his safety of an enemy? or why do you not persuade me to unlearn what I have been taught, that rejecting all the opinions I have hitherto defended I may now, by Cæsar's means, grow wiser, and be yet more obliged to him than for life alone? Not that I have determined anything concerning myself; but I would have it in my power to perform what I shall think fit to resolve upon; and I shall not fail to ask your counsel when I have occasion to act up to the principles which your philosophy teaches. Go tell my son that he should not compel his father to what he cannot persuade him." They withdrew, and the sword was brought by a young slave. Cato drew it, and finding the point to be sharp, "Now," said he, "I am my own master." Laying down the sword, he took up his book again, which it is reported he read twice over. After this he slept soundly; but about midnight he called two of his freedmen, Cleanthes his physician, and Butas, whom he chiefly employed in the management of his affairs. The last he sent to the port to see whether all the Romans were gone; to the physician he gave his hand to be dressed, which was swelled by the blow he had given his slave. This circumstance was regarded as an intimation that he intended to live, and gave great joy to his family. Butas soon returned, and brought word that they were all gone except Crassus, who had staid upon some business, but was just ready to depart. He added that the wind was high and the sea rough. These words drew a sigh from Cato. He sent Butas again to the port to know whether there might not be some one who, in the hurry of embarkation, had forgotten some necessary provisions, and had been obliged to put back to Utica. It was now break of day, and Cato slept yet a little more, till Butas returned to tell him that all was perfectly quiet. He then ordered him to shut the door, and flung himself upon his bed, as if he meant to finish his night's rest; but immediately he took his sword and stabbed himself a little below his chest; yet not being able to use his hand well, for it was still swelled, the blow was not fatal. It threw him into a convulsion, in which he fell from his bed, and overturned a table near it. The noise gave the alarm; and his son and the rest of the family, on entering the room, found him weltering in his blood, and his bowels half out of his body. The surgeon found, upon examination, that his bowels were not cut, and was preparing to replace them and bind up the wound when Cato recovered his senses, thrust the surgeon from him, and tore out his own bowels. He immediately expired. Thus died Cato, in the forty-eighth year of his age.

CATOPTRICS is that part of optics which explains the properties of reflected light, and particularly that which is reflected from mirrors. See Optics.

CATOPTROMANCY (κάτοπτρον a mirror, and μαντεία divination), a species of divination among the ancients by means of a mirror. Pausanias says, that among the Achaians if a person were sick he let down a mirror by a thread into a fountain before the temple of Ceres, and looking in the glass, if he saw a distorted ghastly face he regarded it as an ill omen; but if the face appeared fresh and healthy it was a token of recovery.

CATRINE, a manufacturing village of Scotland, county of Ayr, and parish of Sorn, on the Ayr, two miles S. by E. of Mauchline. It is indebted for its importance to the cotton manufacture established here in 1786. Extensive bleaching-works have also been established here. Pop. of parish (1851) 4174.

CATROU, François (1659-1737), a learned Jesuit, was born at Paris, and after officiating as a preacher, engaged for twelve years in conducting the *Journal de Trévoux*. Besides his contributions to it, he wrote a history of the

Mogul empire, and a history of Rome in which he was assisted by Father Rouillé, who afterwards wrote a continuation of the latter work.

The titles of his works are, 1. *Histoire Générale du Mogol*, 1705, 4to, with *L'Histoire du Regne d'Aurengzeb*, 1715; 2. *Histoire du Fanatisme dans la Religion Protestante, contenant l'Histoire des Anabaptistes, du Davidisme, et des Trembleurs*, Paris, 1733, 3 vols. 12mo; 3. *Traduction de Virgile*, with notes critical and historical, 1729, 4 vols. 12mo; 4. *Histoire Romaine*, 1725-37, 21 vols. 4to.

CATSKILL, a town in the state of New York, capital of Greene county, on the W. side of the Hudson, 32 miles S. of Albany. It stands on both sides of the Catskill creek near its junction with the Hudson, and has some handsome buildings, and a considerable trade. Pop. (1851) 5454.

CATSKILL MOUNTAINS, in the vicinity of the above, bend in the form of a crescent round the Mohawk river; the loftiest peak rising to the height of 3804 feet above tide-water. On the east they are precipitous, but on the west side the descent is comparatively gentle. Many of the wild animals indigenous to the state are still to be found here.

CATTARO, the southernmost of the circles into which the Austrian kingdom of Dalmatia is divided. It is surrounded, except on the sea frontier, by the Turkish dominions, and comprehends the district distinguished as the Bocca di Cattaro. It extends over 585 square miles, or 374,400 English acres, and contains about 40,000 inhabitants. Although corn sufficient for the consumption of five months only is raised, it has a considerable export trade in oil, wine, figs, silk, wool, tallow, wax, honey, and fish. The import trade is conducted chiefly with the Montenegrins and the Turks of the adjoining frontier.

CATTARO, the capital of the above district, is situated on the Bocca di Cattaro, and is strongly fortified both by sea and land. It is the seat of a Catholic bishop, and contains, besides the cathedral, a Catholic collegiate church, a Greek church, and fifteen convents. Though the Romans had a colony at Cattaro, the existence of the present town cannot be traced beyond the sixth century. Cattaro has twice suffered severely from earthquakes, once in 1563, and again in 1667. For some time previous to the treaty of Tilsit the town had been occupied by the Russians. The harbour is good, and capable of accommodating vessels of the largest size. But its trade is now by no means so extensive as it once was. Pop. 4500. E. Long. 18. 47.; N. Lat. 42. 25.

CATTEGAT, an extensive channel or strait lying between Jutland and Sweden, and bounded on the south by the Danish islands of Zealand and Funen. See BALTIC SEA.

CATTI, or CHATTI, a powerful and warlike German nation, who, though defeated by Drusus, Germanicus, and other Roman generals, were never wholly subjugated. Their territory extended from the Weser on the east to the Rhine on the west, and was bounded on the south by the Agri Decumates. Their capital was Mattium, now Maden.

CATTOLICA, a town of Sicily, in the intendancy of and 15 miles N.W. of the town of Girgenti. Pop. 7200. In the vicinity there are extensive sulphur mines.

CATULLUS, CAIUS VALERIUS, a celebrated Roman poet, born at Verona in the year B.C. 87. Though he inherited at least a comfortable independence, his fortune was greatly impaired by his dissipated manner of living in the metropolis. With a view to improve what remained, he visited Bithynia in the train of the prætor Memmius, but with little success. On his return he resided alternately in Rome and at his villas on the promontory of Sirmio and at Tibur. His great merits as a poet procured for him the esteem of Cicero and many other celebrated men of his time. Julius Cæsar was a frequent guest at his father's house; and although the poet ventured, from some temporary cause of irritation, to lampoon that illustrious man, an apology at once effected their reconciliation. Catullus appears to have died in B.C. 47, in the thirtieth year of his age. His extant works comprise 116 poems, including lyrics, elegies, epigrams, and his finest poem on the nuptials of Peleus and Thetis. From his intimate acquaintance with Grecian literature, he is styled *doctus* by Tibullus, Ovid, and others. Original invention and felicity of expression are the peculiar characteristics of Catullus, who may be said to have adorned everything he touched; but the licentiousness of the man is too frequently reflected in his works. Editions—by Aldus, Ven. 1502; Vossius, Lond., 1684; Volpi, Patav., 1710; Doering, Altona, 1834, 2d ed.; Lachmann, Berol., 1829. The best metrical translation into English is that of the Hon. George Lamb, Lond., 1821, 2 vols. 12mo.

CATZ, JACOB, a distinguished Dutch civilian and poet, was born at Brouwershaven in Zealand, in 1577. After residing some time in Leyden and France, he settled at Middleburg, and acquired by his pleadings such reputation that the city of Dort chose him as its pensionary; and some time afterwards Middleburg followed its example. In 1634 he was nominated pensionary of Holland and West Friesland, and in 1648 he was elected keeper of the seal of the same state, and stadtholder of the fiefs; but he soon resigned these offices in order to enjoy the repose which his advanced age demanded. As the post of grand pensionary had been fatal to almost all those who had held it, from the beginning of the republic till that time, Catz delivered up his charge upon his knees, before the whole assembly of the states, weeping for joy, and thanking God for having preserved him from the dangers which seemed attached to the duties of that office. But though he was resolved to spend the rest of his days in retirement, the love of his country induced him to comply with the desires of the states, who importuned him to go on an embassy to England at the delicate conjuncture when the republic found itself compromised during the protectorate of Cromwell. On his return he retired to Sorgvliet, where he lived in tranquillity till the year 1660, when he died. He wrote a great number of poems in Dutch, of which the most esteemed are his *Emblems* and *Country Life*. They have often been reprinted; and from their simple gaiety and morality of tone are highly valued by his countrymen.

CAUBUL. See CABUL.

CAUCASUS, a vast chain of mountains extending across that isthmus of Western Asia which is bounded by the Black Sea on the west and by the Caspian on the east. Commencing near the mouth of the river Kouba, which falls into the Euxine, it proceeds in a south-easterly direction, gradually increasing its distance from that sea, and then turning towards the east traverses Mingrelia and Imeritia. Approaching the source of the river Kouma, a ridge diverging to the south enters Georgia near the origin of the Kur, which rises in the mountains of Kars, while the main chain, advancing to the western shores of the Caspian, proceeds through the provinces of Daghestan and Shirvan, once belonging to Persia, but now nominally under the government of Russia. Here penetrating Ghilan, it is connected in a continued chain by the mountains of Mazanderan and the Paropamisan with the Hindu Koh or Indian Caucasus, a part of the great Himalaya range. Finally, taking a south-eastern direction, it terminates at the peninsula of Apsheron, which runs out into the Caspian Sea. It is also connected by means of a secondary range near the Black Sea with the mountains of Ararat; while the spurs which are thrown out from the main ridge towards the north are gradually lost in the immense steppes of southern Russia. The length of the whole chain from the mouth of the river Kouba to the peninsula where it terminates, is estimated at from 650 to 700 miles. The breadth from Mosdok to Tiflis is computed at 180 miles; but, with its various parallel chains and ramifications, the average cannot exceed 140 miles.

The Caucasian chain consists of mountains rising to a great elevation, some covered with forests, others bare and arid; while the summits of many are covered with perpetual snow. Their geological structure is very various. A considerable portion of the elevated region consists of white limestone, behind which are higher ridges of black slate. The most lofty mountain peaks are composed of basalt, granite, schistus, porphyry, and the more ancient formations. The mountains to the east of Elburz reach a much greater altitude than those which are situated between it and the Black Sea, towards which they gradually decline, terminating in a series of hills of very moderate elevation. Many of those parts of the Caucasian chain which reach the greatest altitude are exceedingly craggy and precipitous, and cannot be traversed without great danger at any season of the year; the narrow path by which the traveller is compelled to proceed often leading immediately over precipices of immense height, guarded by rocky walls which hang threateningly overhead. In some directions, immense masses of mountain present the appearance of having been rent asunder by some dreadful convulsion of nature. Numerous cataracts rush with a thundering noise over the abrupt precipices into the abysses below, from which they descend to the more level portions of the country. In other parts, the mountains stretch out into level plains; and many of the intervening valleys overhung by these immense precipices are remarkable for their fertility and beauty.

The Beshtau (corrupted from Besh Dagh, *i. e.*, the five mountains), or mountains of Pyätigorsk, situated to the S.W. of Georgiefsk, form, as it were, the advanced post of the great Caucasian chain. They are connected with it by means of a ridge which proceeds in a south-easterly direction between the rivers Kouma and Kouba, gradually increasing in elevation until it joins the Elburz, the loftiest mountain of the whole chain. The highest of the two conically shaped summits of the Elburz is said to reach an altitude of nearly 18,000 feet. Among the mountain tribes, whose superstitious faith represents its hollows and caverns as the entrance to the abode of the Peris, or fairies of eastern mythology, it is known by the name of Dshin Padishah, or king of spirits. North-west from the Elburz, the Pelav-Tepesh, the Oshten, the Idokopas, and the Shapsuch, are the highest mountains on the eastern coast of the Black Sea. In a south-eastern direction near the great Georgian military road, is the lofty Kasbek, which is considered to form the central point of the Caucasian range. At the foot of the snow-covered Krestovaya, or mountain of the cross, is the post station of Kobi, not far from which is the hamlet of Baidar, inhabited by the Ossetes, whose only duty is to assist such travellers as may have gone astray during the alarming snow-storms by which these elevated regions are so often visited. Between the Kasbek and the peninsula of Apsheron, one of the most remarkable mountains is the Besh Parmak Dagh, or mountain of the five fingers, so named from its peculiar form, which rises to a considerable height close to the Caspian Sea. The communication between Russia and its Transcaucasian provinces is maintained by means of two narrow passes or defiles. The most important is that of Dariel, known to the ancients under the name of the Caucasian Gates, through which the northern barbarians formerly made their way into the fairer regions of Asia Minor, and the great Georgian military road used by the Russians for the conveyance of troops, war-stores, and merchandise now proceeds. In some parts of this dangerous pass situated far above the line of snow, the narrow path leads immediately over the most fearful precipices and through rugged defiles such as the traveller meets with nowhere amid the most mountainous regions of Europe. All communication along this road is frequently stopped for weeks together by a sudden fall of snow, or the descent of an avalanche. The Caspian pass, formerly known as the Albanian Gates, is situated between the Caspian Sea and the precipitous rocks crowned by the Russian fortress of Derbend. The road which proceeds through this pass, leading from the town of Kislyar to that of Bakou, is connected by a third, which joins Yekaterino-gradskaya and Kislyar with the great Georgian road. The communication between the forts on the coasts of the Black and Caspian Seas is maintained by means of steam ships and small war vessels named Barkasses, which are propelled either by sails or oars.

Although a great number of mountain streams have their origin in the Caucasus, most of them are only insignificant tributaries by which the principal rivers are fed. The Kur, anciently the Cyrus, which takes its rise in the mountains of Kars, and directs its course through the middle of Georgia to the Caspian Sea, is the largest of the Transcaucasian rivers. From the northern declivity of the Caucasian range, the Terek, rising at the foot of Mount Kasbek, and rushing through the pass of Dariel, proceeds to the same destination. The Kouba which has its origin in the marshes on the north-western declivity of the Elburz, after sending two branches to the Sea of Azof, falls into the Black Sea. Along the Kouba, the Malka, and the Terek, is that great line of forts and Cossack stations extending almost without interruption from the Caspian to the Black Sea. The climate of the Caucasian countries, although generally speaking salubrious, is very various. The mountain tops covered with snow may be seen from valleys, gardens, and orchards, in which the most beautiful flowers and the richest fruits are growing. Into some districts, such as Imeritia and the neighbourhood of Derbend, the stranger who is unaccustomed to the peculiar nature of the climate cannot enter without great risk. The natives of the districts bordering upon the Black and Caspian Seas frequently suffer from severe fevers caused by their exposure to the pestilential exhalations rising from their marshy banks, and the unhealthy sea winds and mists which often prevail. Georgia, Mingrelia, Abasia, and the north of Daghestan, are all said to possess an excellent climate. In many parts the inhabitants of the plains are compelled to take refuge in the mountains during the heat of summer, while the mountaineers during the severity of winter descend with their flocks to the valleys. The vegetation of these regions, which differs in no respect from that usually seen in the two temperate zones, is at once various and abundant. Immense forests of pine and fir, often reaching an elevation of nearly 8000 feet, crown the mountain heights. The declivities and valleys are distributed into orchards, vineyards, corn fields, and pastures in rich variety. Grapes, chestnuts, figs, peaches, as well as grain of every description, rice, cotton, hemp, &c., grow in great abundance all over the country. The fruit trees generally attain a height and thickness which astonish the traveller from the most fertile regions of Europe. Among the natural productions of the Caucasus may be mentioned nitrate of potass, mineral pitch, and the hot sulphur springs which are found in different parts of it. The Ghebers, or fire worshippers, still perform the ceremonies of their faith in presence of the "eternal fires," which burn on the peninsula of Apsheron. These fires are not produced, as described in the works of earlier travellers, by the naphtha with which the soil is impregnated, but, according to M. Eichwald of Wilna, "by hydrogen gas (probably carburetted hydrogen) which rises through cracks and openings of the calcareous rocks, and on the approach of a flame takes fire, and continues to burn. It never takes fire spontaneously, nor by the approach of red coal, if not burning with flame. The gas, as it escapes from the rock, is without smell—is not sensibly warm—and on being respired does not occasion any disagreeable feeling. It burns with a yellowish-white flame, and forms with atmospheric air an exploding gas."

Caucasus.

The Caucasian territory, which nominally forms one of the provinces of Russia, is bounded on the north by the rivers Kouba and Kouma, on the south by the Araxes, on the west by the Black Sea, and on the east by the Caspian Sea. It formerly consisted of the provinces of Georgia, Imeritia, Mingrelia, Circassia, Daghestan, Shirvan, and Caucasia. Its two principal divisions at present under the Russian government are the Caucasian province, of which Stavropol is the capital, and Transcaucasia, in which the principal city is Tiflis, the capital of Georgia. By an imperial ukase issued in the year 1846, Transcaucasia was further divided for the administration of its affairs into the four governments of Derbend, Shemaka, Kutaïs, and Tiflis. The principal tribes inhabiting the Caucasus are the Georgians, Imeritians, and Mingrelians of the race of Kartvel, the Misdsheghi or Kists, the Lesghians, the Turks or Tatars, the Armenians, the Abasians, the Tscherkessi or Circassians, called by themselves Adighé, the Kabardians, and the Ossetes, besides a great number of Jewish and Cossack settlers. Several of the tribes, particularly the Circassians, Georgians, and Imeritians, are accounted the handsomest people in the world, the men being generally tall and powerful, the women slender and graceful, and both having regular features and expressive eyes. The Lesghians who inhabit a great portion of Daghestan or the mountain land, are one of the most warlike, chivalrous, and independent of the Caucasian races. The Suanians, who possess one of the loftiest inhabited valleys of the range, are remarkable for their physical strength and agility. The Mingrelians are said to be the descendants of the ancient Colchians. The Abasians and Ossetes are described as the rudest of the mountain tribes. With dark complexions and irregular features, the former have generally a very repulsive expression of countenance, emblematic of their moral and social inferiority. All the inhabitants of these countries are exceedingly fond of adorning their persons; and the traveller is often struck by the appearance of a splendidly equipped cavalier issuing from a cottage of the most miserable description. The Circassian and Georgian females are much sought after by the eastern princes, to whom they are sold even by their fathers and brothers. Most travellers assert that, with the exception of those parts of the country in which the principal races dwell, it is utterly impossible to determine the territorial boundaries of the Caucasian tribes. The state of religion amongst them is equally unsettled and perplexing. Many profess Christianity in a form which retains few or none of its distinctive principles, others are bigoted Mohammedans, and the remainder idolaters. The nobles sometimes profess one form of religion, and the great body of the people another. Many of the old Christian temples, which remain to this day in several districts, contain at the same time the emblems of Christianity in the images of the Virgin and the saints, of Mohammedanism in inscriptions from the Koran, and of idolatry in the idols to whom they bow.

Trade and commerce.

The trade and commerce of the Caucasian provinces are mostly in the hands of the Armenians, who inhabit the various districts of the country, but particularly that of Derbend on the shores of the Caspian. The inhabitants of Daghestan, so celebrated for its warlike and independent tribes, are also very enterprising in their commercial undertakings. In addition to weapons of various kinds, in the manufacture of which they excel, they produce cloth, silk, and beautiful silver work. The Abasians dispose of considerable quantities of a peculiar kind of honey, which, from its intoxicating influence, the Mohammedans are said to use instead of wine. Saltpetre is produced in a very curious manner in Suanethi. A portion of land which has been protected against the influence of snow or rain is covered on the approach of frost with great quantities of it. The inhabitants of this district also dig from the lower regions of Mount Elburz considerable quantities of sulphur, from which they produce gunpowder for sale among the neighbouring tribes. In the valleys of the Kur, the Phasis, the Alasau, and the Yora, the vine is cultivated with much success. The wine of Kakhetie, which is said to resemble that of Burgundy, is particularly celebrated for its excellence. In some of the Russian provinces the mulberry tree and the cotton plant are cultivated with great profit. The sugar-cane has been successfully introduced into the khanate of Talisch. Madder, saffron, rice, millet, barley, Indian corn, wheat, and tobacco, are among the principal articles of export.

The nations of the Caucasus, whose history has been regarded with the deepest interest in modern times, are the Lesghians and Circassians. The Lesghians inhabit the greatest part of Daghestan, which is bounded on the east by a chain of mountains running parallel with the coast of the Caspian, and penetrated in every direction by lofty and rugged spurs from the main chain. The Circassians occupy the mountain territory extending between the river Kouba and the Black Sea. The attempted conquest of these provinces, to which the Russians can lay no claim except that of the stronger over the weaker, has already cost them an immense amount both of blood and treasure. Especially since the year 1829, when by the treaty of Adrianople the Turks delivered over to the Muscovites a region over which they never possessed any sovereignty, the Russian armies have been completely baffled in all their attempts to establish the authority of the czar. The Russians have had to encounter immense difficulties, to traverse dangerous passes, to burn down forests, and to sacrifice immense numbers of lives, in order to gain small portions of territory. The war was for a long time chiefly maintained by the Circassians under their native chiefs; and no sooner did their exertions relax in consequence of the exhaustion caused by a long-continued contest, than a new enemy to Russia arose on the shores of the Caspian. Schamyl, the most devoted follower of the heroic Kasi Mullah, placed himself, on the death of that chief, at the head of the Lesghians. At once the prophet and the warrior of his race, by his enthusiasm and bravery he soon gained the confidence of the tribes, and prevailed upon them to follow a united and determined plan of action under his authority. His influence was daily increased, not only by the victories which he gained, but by the successful manner in which he frequently delivered himself and his followers from the most imminent dangers. His own escape from the rocky fortress of Achulko, where he was completely invested by the forces of General Grabbe, appeared both to his own countrymen and the enemy almost miraculous. In the year 1840 he even ventured to storm many of the Russian forts in the vicinity of the Black Sea; and although unable to retain them in his possession, secured an immense quantity of gunpowder and other munitions of war. The great exertions which were made by the Russians in the following year to reduce the tribes yet unsubdued, and those which had risen against their authority, were completely defeated by his indefatigable activity and bravery. In the year 1842, when the mountain tribes were filled with the greatest alarm in consequence of the advance of General Grabbe, that formidable enemy was completely defeated by Schamyl in the woods of Itchkeri. The Circassians, after again renewing their attacks upon the Russians in the neighbourhood of the Black Sea, were ultimately driven back to their fastnesses; but Schamyl still continued to maintain his position on the Caspian, and inflicted severe losses upon the armies of the enemy. The Russians were evidently at a loss how to proceed against a chief who had baffled all their schemes, who had been a prisoner in their hands, whose rocky home had been frequently in their possession, who had incurred the most imminent dangers and been driven to the greatest emergencies, and who was still opposing them with unconquerable resolution, watching the progress of their troops, cutting off their supplies, and harassing them by constant attacks. Various Russian generals were sent in succession to the Caucasus, new plans of action, defensive and offensive, were tried, but all without effecting any permanent conquest. In the year 1850 the Czarovitch made a progress to Tiflis, and was attacked on his journey by the soldiers of Schamyl in the immediate vicinity of some of the Russian forts. The armies of the czar may occasionally, with the sacrifice of a great number of lives, effect a march over the mountains, but no permanent conquest is achieved. With all the exertions of many years, their real authority is still confined to Georgia, the plains, and the immediate neighbourhood of the forts, of which so many have been erected all over the country. Georgia has now been subject to the civil and military government of Russia for more than half a century, and the result has not been at all favourable to that country. In most other parts of the Caucasian territory, the period during which the Russians have been

connected with them has been one of almost ceaseless war, in which little progress can have been made in the civilization of the people. With that indomitable spirit of independence which most of the Caucasian tribes have displayed, it is scarce to be expected that they will ever cultivate the arts of peace under the domination of the Russians, or while the Russian troops remain in possession of any portion of their country. Many of the inhabitants are inclined to commercial pursuits; and if they were not disturbed by the alarms of hostile invaders, commerce would do more to advance the general cultivation of the people than its conquest by a nation which is itself only half civilized.

It is very difficult, in the absence of all satisfactory statistical returns, to ascertain the exact amount of the population of the Caucasus. Those who by a long residence in the country have been enabled to form the most correct estimate, are of opinion that it cannot be less than one million or one million and a half. This number includes only the male portion of the population, no statement of the amount of the female portion being given in the Russian returns. The various principal races may be calculated in the following proportions:—

Tribes of the race of Kartvel	300,000
Armenians	135,000
Turkish and Persian tribes	350,000
Lesghians	350,000
Abasians and Circassians	150,000
	1,285,000

Little doubt can be entertained but that the Kists, Ossetes, and other tribes, the number of whose inhabitants cannot be certainly determined, will raise the population of the Caucasus to the amount stated. (See *Die Völker des Kaukasus*, by F. Bodenstedt, Berlin; and *The Tribes of the Caucasus*, by Baron von Haxthausen, London, 1855.

CAUDEBEC, a seaport town of France, in the department of Seine Inférieure, on the right bank of the Seine, at the mouth of the Caudebec. Pop. 2500.

CAUDETE, a town in the province of Albacete, Spain. It contains about 1200 houses, a town-house, prison, school of primary instruction, Carmelite convent and several other religious institutions. The inhabitants are engaged almost exclusively in agriculture and the manufacture of coarse fabrics for home consumption. The town was once fortified, and possesses some Roman remains. Pop. 5502.

CAUFIRISTAN, a mountainous country of Asia, situated partly upon the Hindu Koh, and partly upon the Beloor Taugh. It lies between Lat. 35. and 36., and Long. 69. 20., 71. 20. Its boundaries are Caubul, Budukshaun, and Bulkh. The name Caufiristan, signifying "land of infidelity," has been given to the country by the neighbouring Mussulmans, in consequence of the rejection of Mohammedanism by the inhabitants. These are called Siyah Posh or "black clad," from wearing black goatskin dresses. According to Elphinstone in his "Account of Caubul," the people "have no general name for their nation. Each tribe has a peculiar name, for they are all divided into tribes, though not according to genealogies but geographical position, each valley being held by a separate tribe." The country is drained by four considerable rivers, the Kama, the Alingar, the Alishang, and the Tagoa, which are reported to rise in the Hindu Koh, and which, holding a course generally to the S.W., pass into Afghanistan, and fall into the river of Caubul. Each river flows down a great valley inclosed on each side, S.E. and N.W., by lofty mountains, having in various places summits covered with perpetual snow, and furrowed by numerous valleys of inferior size to that through which the river takes its course. So steep are the slopes of the mountains, that in the villages which are always built on the declivities, probably from regard to purposes of defence, the houses are reared several stories high, with their backs against the precipice behind, in such a manner that the roofs of one row form the street for the one immediately above it. In person the Siyah Posh are strongly marked specimens of what is called the Caucasian variety of the human race; and in their fine figures, fair complexions, and regular features, bear a strong resemblance to the Circassians. They acknowledge a supreme deity, whom they call Imra; but they also worship numerous idols, which they say represent great men of former days, who intercede with the deity in favour of their worshippers. They venerate stone posts resembling *lingas*, and make offerings by throwing flour, butter, and water on them; and also sacrifice various animals, burning part of the flesh as an offering, and feasting on the rest. The Caufirs are a very martial race, being engaged in incessant warfare with their Mohammedan oppressors, by whom they are surrounded. They bear shields for defence; and for offensive arms, swords, spears, knives, and bows and arrows. Of late years they have begun to provide themselves with matchlocks purchased from the Afghans. Though readily admitted to quarter by the Mohammedans, in consequence of their marketable value as captives, they seldom spare the life of an enemy at their mercy. On the return of a party from an expedition, those who have slain Mohammedans are presented by the maidens with dried fruits; while those who failed in attaining this distinction are pelted with ashes. The female relatives of those who have slain Mohammedans are allowed the exclusive use of certain honorary distinctions in dress. The Siyah Posh have never been conquered. Tamerlane, who subdued so many kingdoms and empires and overcame all other resistance, from the Hellespont to Central India and from Syria to Moscow, retired baffled from his attempt to subjugate Caufiristan. About seventy years ago the adjoining Mohammedan powers confederated for the purpose of waging a religious war, and forcing this people to embrace Islamism. The Khan of Budukshaun, the chiefs of Kooner, of Bajour, and of several of the Eusufzai tribes, by simultaneous marches met in the heart of Caufiristan; but, unable to keep their ground, were forced to evacuate the country after suffering considerable loss.

The Caufirs are hospitable in the extreme. A stranger arriving at one of their villages is not only welcomed, but is expected to visit each of the principal men, where he is regaled with every dainty which the house can afford. Their wealth consists of cattle and slaves. The government is chiefly conducted by consultations among the rich men. Their dress consists principally of goats' skins with the hair turned outwards, two of which form a vest, and other two a kind of petticoat. They are less addicted to hunting than the Afghans. The favourite amusement is dancing, of which they never tire. They cannot accommodate themselves to the Asiatic practice of seating themselves cross-legged on the ground, but sit in the European manner on benches and stools. They also use tables, and drink wine copiously, though not to intoxication, out of silver cups. These European habits have given rise to the hypothesis of their being a Greek colony, left during the expedition of Alexander. They are themselves fond of claiming affinity with the Feringis or Europeans; and on the recent invasion of Afghanistan by the British, sent a mission to express their gratification at the arrival of so many brethren. The two chief towns, or rather villages, of the Caufirs, are Caumdaish and Tsokooee. The former contains five hundred houses.

CAUKING, or CAULKING, the driving of oakum or old rope untwisted into the seams between the planks in a ship's deck or sides, to prevent the entrance of water or leakage. The seams are then covered with melted pitch or rosin, to keep the oakum from rotting.

CAULABAGH, a town of Hindustan, in the British province of the Punjaub, situate on the right or west bank of the Indus, where it finds a passage through the salt range which stretches from Afghanistan into the Punjaub. It is a singularly built place, the houses being situated on terraces cut out of the declivity of the hill. In the vicinity of the town are large rocks, which yield an inexhaustible

store of the pure rock salt; and there is, besides, a considerable manufacture of alum. In both of these articles an extensive trade is carried on with the neighbouring provinces, which proves highly beneficial to the inhabitants. The river Indus, which here flows in one channel, is navigable from the sea; and the facilities of communication which have been established by means of government steam vessels between Kurrachee and Mooltan are about to be extended to this town. The proper name of the town is Khara Bagh, or Garden of Salt. E. Long. 71. 30., N. Lat. 32. 57.

CAULIFLOWER, a variety of cabbage. See HORTICULTURE.

CAURSINES, or *Caursini*, Italian usurers who first came into England about the year 1235, terming themselves the pope's merchants, but were driven out of the kingdom about the year 1250 on account of their merciless exactions.

CAUSE, that from which anything proceeds, or by virtue of which anything is done; or an antecedent relatively to an invariable consequent. It stands opposed to effect. See METAPHYSICS.

CAUSEWAY, or CAUSEY, a massive construction of stones, stakes, and fascines, or an elevation of fat viscous earth, well beaten, serving either as a road in wet marshy places, or as a mole to retain the waters of a pond, or prevent a river from overflowing the lower grounds. See ROAD. The word is derived from the French *chaussée*, anciently written *chaulsée;* and that, again, from the Latin *calceata*, or *calcata*, which, according to Somner and Spelman, comes *a calcando*.

CAUSEWAY most generally signifies a common raised way, maintained and repaired with stones and rubbish.

CAUSSADE, a town of France, department of Tarn and Garonne, pleasantly situated in a fertile district near the Caude, twelve miles N.E. of Montauban. It has manufactures of woollen and linen goods, and some trade in corn, saffron, and truffles. Pop. about 4000.

CAUSSIN, NICHOLAS, surnamed the Just, a French Jesuit, born at Troyes in Champagne, in 1583. He taught rhetoric in several of the colleges of the order, and as a preacher gained great reputation. This procured him the preferment to the office of confessor to Louis XIII.; but he discharged his duties too faithfully for Cardinal Richelieu, who procured his dismissal. He was exiled for some time, but afterwards returned, and died in the Jesuits' convent at Paris in 1651. The most popular of his works, which are numerous, is that entitled *La Cour Sainte*, 5 vols. 12mo.

CAUSTICS (καύστικος from καίω, καύσω, to burn), certain substances which when applied to the skin corrode and destroy its texture. Of these there are the common stronger caustic, the common milder caustic, the antimonial caustic, and the lunar caustic or fused nitrate of silver. See CAUTERY.

CAUSTIC *Curve*, in the higher geometry, a curve formed by the concourse or coincidence of the rays of light reflected from some other curve. See OPTICS.

CAUTERY, in *Surgery*, a burning or searing, as of morbid flesh, by the application of caustic medicines, or by a hot-iron. The first is termed *potential cautery*, the latter *actual cautery*.

CAUTIONER, in *Scots Law*, one who becomes bound for another to the performance of any deed or obligation.

CAVA, a town of Naples, province of Principato Citra, 26 miles S.E. of Naples. Including the adjoining and dependent villages, it has about 13,000 inhabitants. It is the seat of a bishopric, and has a cathedral, diocesan seminary, convent for noble ladies, and manufactures of silk, cotton, and woollen stuffs. In the vicinity is the famous Benedictine abbey called *La Trinità Della Cava*, with its fine library and valuable archives.

CAVAILLON, the ancient *Cabellio*, a town of France, on the Durance, department of Vaucluse, arrondissement and 13 miles S.E. of the town of Avignon. The town is ill built and dirty, but carries on a considerable trade, and the vicinity is very productive. Remains of a Roman arch are seen here. The only building worthy of notice is the town-hall. Pop. 4000.

CAVALCANTI, GUIDO, an Italian philosopher of the seventeenth century, whose father is consigned by Dante in the *Inferno* to the region of the condemned, on account of his Epicurean philosophy. He has written several poems, consisting of sonnets and canzones, chiefly in honour of Mandetta, a lady whom he met at Toulouse.

CAVALIER, a horseman, especially an armed horseman; a knight. During the civil war which brought Charles I. to the scaffold, the adherents of the king were first called Cavaliers, in contradistinction to the Roundheads or friends of the parliament.

CAVALIER, in *Fortification*, a sort of interior bastion elevated several feet above the principal bastion of a fortress.

CAVALIERI, BONAVENTURE (1598-1647), an eminent mathematician, a native of Milan, and friar of the order of the Jesuati of St Jerome, was the professor of mathematics at Bologna, where he published several mathematical books. The most famous of these are entitled *Directorium generale Uranometricum; Geometria indivisibilibus Continuorum*, &c.; *Trigonometria plana et spherica*, and *Exercitationes Geometricæ*.

CAVALLINI, PIETRO, an artist of the earliest epoch of the Roman school, who was taught painting and mosaic by Giotto, while he was employed at Rome; and it is believed that he assisted his master in the mosaic of the *Navicella*, or ship of St Peter, in the porch of the church of that saint. Lanzi describes him as an adept in both arts; and mentions with approbation his grand fresco of a Crucifixion at Assisi, still in tolerable preservation. Cavallini has another claim to notice, since, according to George Vertue, it is highly probable that he executed the mosaics and other ornaments of the tomb of Edward the Confessor in Westminster Abbey, by order of Henry III. The work, however, must have been executed by him in Rome, where he appears to have constantly resided. He died in 1344 at the age of 85.

CAVALLO, TIBERIUS, an electrician and natural philosopher, son of a physician established at Naples, was born in that city, March 30, 1749.

His father died when he was only eleven years old, but he received a liberal education through the kindness of his friends, and completed his studies at the university of Naples. He was originally destined for commerce, and came to England in 1771, in order to obtain more complete information respecting the various objects of mercantile pursuit. But he soon abandoned his intention of adopting that mode of life, and determined to devote his time almost exclusively to the cultivation of science, and to the literary employments connected with it. The splendid improvements which had been lately made in electricity easily directed his earliest attention to that amusing department of natural philosophy; but his studies were by no means confined to that subject, and the extent of his diversified researches may be understood from an enumeration of his principal publications.

1. *Extraordinary Electricity of the Atmosphere in October* 1775. *Phil. Trans.* 1776, p. 407. This observation was made at Islington, where the author then resided; and he seems to have been in some danger of becoming, like another Richmann, a martyr to his zeal in pursuit of his favourite science; for he says that he felt a number of severe shocks while he was holding the wire of his kite.

2. *An account of some new Electrical Experiments. Phil. Trans.* 1777, p. 48. He here describes two atmospherical electrometers, and an exhausted tube containing some quicksilver, for illustrating the nature of electrical excitation. A paper of Mr Henly, in the same volume, contains

also some communications from Mr Cavallo, and in particular a remark on the opposite electricities which he detected in the bow and strings of his violin.

3. *New Electrical Experiments.* *Phil. Trans.* 1777, p. 388. Relating to changes of the colours of pigments, with a description of a pocket electrometer.

4. *A complete Treatise on Electricity*, 8vo. London, 1777. German by Gehler, 8vo. Leipz. 1785. French by Silvestre, 8vo, Paris, 1785. Ed. 4, 3 vols. 8vo, London, 1795.

This essay contains a clear and familiar account of the principal facts respecting electricity, which had been discovered at the time of its publication, as well as of the best apparatus and of the most interesting experiments. The first part relates to the general laws of the science; the second to the hypothetical theories by which different authors have attempted to explain them, but without any mention of the calculations of Alpinus and Cavendish; the third part gives an account of the practical arrangement of electrical apparatus, and the fourth of some original experiments and instruments; the fifth part in the later editions is a republication of the author's *Essay on Medical Electricity.* To the fourth edition a third volume is added, containing an account of the recent discoveries respecting animal electricity; of the author's multiplier for detecting the presence of small quantities of electricity, by the repeated operation of two condensers connected together; and of some original and very important experiments relating principally to the effect of the contact of different metals with each other, and exhibiting an imperfect outline of those properties, which have since furnished Volta and Davy with their ingenious explanations of the phenomena of the electrochemical battery.

Mr Cavallo has inadvertently attributed to Nollet the honour of having first entertained the opinion of the electrical nature of thunder and lightning; and the German translator has thought it necessary to vindicate the scientific character of his own country, by laying claim to this conjecture on behalf of Winkler; but Mr Silvestre has remarked, with a laudable impartiality, that both Germany and France must on this occasion give way to England, since the first suggestion of the identity is found in a paper of Stephen Gray, published in the *Philosophical Transactions* about 1735.

5. *An account of some new Experiments in Electricity.* *Phil. Trans.* 1780, p. 15. Consisting of remarks on Professor Lichenberg's discovery of the peculiarity of the figures exhibited by strewing powders on the cake of the electrophorus; with an account of two improved electrometers.

6. *Thermometrical Experiments and Observations.* *Phil. Trans.* 1780, p. 585. This was a Bakerian lecture, delivered by appointment of the president and council of the Royal Society, an appointment which entitles the lecturer to a small fee, left by the will of Mr Henry Baker, but which is commonly considered as rather complimentary than lucrative. These experiments relate to the effect produced by colouring the bulb of a thermometer exposed to the sun's rays, and to the intensity of heat at different distances from its source. The most refrangible colours appeared to absorb the most heat; and it was observed that even the day-light, without sunshine, occasioned a perceptible difference in the indications of the different thermometers.

7. *An Essay on Medical Electricity*, 8vo, London, 1780. It is seldom that persons not medical have been sufficiently incredulous in their opinions respecting the operations of remedies; and the whole of the expectation held out in this work has certainly not been fulfilled by later experience; but, as a candid and distinct relation of cases, it may still have its value.

8. *Account of a Luminous Appearance.* *Phil. Trans.* 1781, p. 329. One of the permanent arches since found to be connected with the aurora borealis. It was so bright that the stars could not be seen through it, and lasted about an hour.

9. *Thermometrical Experiments.* *Phil. Trans.* 1781, p. 509. A Bakerian lecture, relating to the evaporation of ether, to the expansion of mercury, and to a thermometrical barometer; that is, a very delicate thermometer for ascertaining the temperature of boiling water at different heights above the level of the sea, according to the idea then suggested by Sir George Shuckburgh, and very lately resumed by other natural philosophers. Mr Cavallo observes that the instrument has the advantage of being very portable; but that unless the quantity of water be considerable, its boiling temperature will be somewhat unsteady.

10. *A Treatise on the Air, and other Permanently Elastic Fluids*, 4to, Lond. 1781. This elaborate work commences with the principles of chemistry and of hydrostatics, and proceeds to relate all the known properties of the different kinds of elastic fluids, many of which had been very lately discovered. These are followed by an account of some original experiments, for example, on the gas produced by the deflagration of gunpowder, which is found to be chiefly nitrogen and carbonic acid, without any nitric oxide; on the explosion of hydrogen mixed with atmospheric air, and on the evolution of gas from plants, respecting which the author finds some reason to differ from the opinions of Dr Ingenhurz. Considering that Mr Cavendish had not then discovered the composition of the nitric acid, it must be allowed that the experiments on gunpowder may justly be deemed an important step in the progress of chemical science.

11. *Description of an Improved Air-Pump.* *Phil. Trans.* 1783, p. 435. The improvement was made by Haas and Hurter, and consisted in a mode of opening the valve of oiled silk mechanically, when the elasticity of the air became too weak to raise it. The rarefaction obtained went to about the thousandth of an atmosphere. In this state the air transmitted electricity, with a light equably diffused; and the balls of the electrometer exhibited no divergence. Some later improvements are said to have carried the rarefaction to $\frac{1}{3000}$.

12. *Description of a Meteor.* *Phil. Trans.* 1784, p. 108. This observation was made at Windsor, and is highly valuable, from the circumstance of a noise like thunder having been heard, about ten minutes after the explosion of the meteor was seen; hence the author concludes that its direct distance was 130 miles, and its height 56½.

13. *The History and Practice of Aerostation*, 8vo, Lond. A work of temporary rather than of permanent interest; but which it was the more natural for Mr Cavallo to undertake, as he was one of the first who had made experiments on the means of employing hydrogen for raising bodies into the air by its levity.

14. *Mineralogical Tables*, f. Explanation, 8vo, Lond. 1785; containing a comparison of the different systems of mineralogical arrangement then most generally adopted, but at present almost wholly superseded by later methods.

15, 16. *Magnetical Experiments and Observations.* *Phil. Trans.* 1786, p. 62; 1787, p. 6. Two Bakerian lectures. The former relates chiefly to the magnetism of brass, and of some other metals, generally rendered discoverable by hammering them. In the latter the same subject is continued; and it is shown that the same powers may be detected in the metals in question without hammering them, if they are placed on a very clean and wide surface of quicksilver. The limit at which red hot iron begins to be attracted by a magnet is found to be the heat at which it

ceases to be visible in the day-light. A considerable change is observed in the magnetic powers of iron during its solution in acids; and the author endeavours to apply these experiments to the explanation of the variation of terrestrial magnetism, as derived from the effects of heat, and from internal changes in the constitution of the earth. Mr Bennet has endeavoured to explain the phenomena observed by Mr Cavallo, from the accidental operation of foreign causes; but he has not been perfectly successful in the attempt.

17. *A Treatise on Magnetism in Theory and Practice*, 8vo, Lond. 1787, ed. 3, 1800. The arrangement resembles that of the Treatise on Electricity. Under the head of Theory the name of Alpinus is mentioned with due respect. The original experiments are chiefly reprinted from the *Philosophical Transactions*. There is also a description of an improved mode of suspension for a magnetic needle; and there are several letters from Dr Lorimer on the terrestrial variation.

18. *Of the Methods of manifesting the presence of small quantities of Electricity*. *Phil. Trans.* 1788, p. 1. In this Bakerian lecture, Mr Cavallo proposes an improvement on Volta's condenser, and makes some remarks on Mr Bennet's doubler, which he thinks objectionable on account of the impossibility to deprive the plate of a small quantity of electricity adhering to it. His own instrument has the advantage of avoiding the friction to which the condensers and doublers in their original form were liable.

19. *Of the Temperament of Musical Intervals*. *Phil. Trans.* 1788, p. 238. The author's particular object is to calculate the exact scale for the division of a monochord, according to the system of a perfectly equal temperament; but he very candidly remarks, that, " for playing solos," the usual temperament is the best, " giving the greatest effect to those concords which occur most frequently;" and he says, that when a harpsichord was tuned according to the scale laid down on this monochord, the harmony was perfectly equal throughout, and the effect " the same as if one played in the key of E natural on a harpsichord tuned in the usual manner."

20. *Description of a new electrical Instrument, capable of collecting together a diffused quantity of Electricity*. *Phil. Trans.* 1788, p. 255. This collector consists of a fixed plate of tin, situated between two movable ones; it is said to be more certain in its operation than the condenser, the results of which are liable to considerable irregularities from various accidents, and to be more free from the inconvenience of permanent electricity than the doubler.

21. *Description of a Micrometer*. *Phil. Trans.* 1791, p. 283. *Description and use of the Mother of Pearl Micrometer*, 8vo, Lond. 1793. A thin slip of mother of pearl with a fine scale engraved on it, placed in the focus of the eye-piece of a telescope. Its principal use is for ascertaining the distance of an object of known dimensions by its apparent magnitude thus measured; for instance, to enable one to judge of the distance of a body of troops in military operations. The mother of pearl is found to be more convenient than glass for receiving the divisions, and to be sufficiently transparent for transmitting the images of the respective objects.

22. *On the Multiplier of Electricity*. Nicholson's *Journal*, i. p. 394, 1797. In this letter Mr Cavallo attempts to show the advantage of his instrument over doublers of all kinds. Mr Nicholson, in a very respectful answer, expresses his doubts whether the objections to the doubler do not arise from its extreme sensibility only, as demonstrating the existence of an electricity too weak to affect the other instruments compared with it. Mr Cavallo had however remarked, that the inconvenience partly arose from the greater intensity of the charge committed to the plate of the doubler during the operation, which required a longer time for the restoration of the natural equilibrium.

23. *An Essay on the Medicinal Properties of Factitious Airs, with an Appendix on the Nature of the Blood*. 8vo, London, 1798. The modern improvements in pneumatic chemistry have been still less productive of advantage to practical medicine than the discovery of the powers of electricity, and this work can scarcely be considered as having conferred any material benefit on the public. The observations on the blood are chiefly the result of a minute and careful microscopical examination of its particles, but the author was not particularly happy in the light which he employed for viewing them.

24. *Elements of Natural or Experimental Philosophy*, 4 vols. 8vo, Lond. 1803. This work, the last and most valuable of the author's publications, will long serve as a useful manual of the most important parts of the mechanical and physical sciences. The first volume is devoted to mathematical and practical mechanics, beginning with matter and motion, and proceeding to simple machines. The second relates, first, to fluids, to the principles of hydrostatics, cohesion, hydraulics, pneumatics, sound, and music; and, secondly, to the most important parts of chemistry. In the third volume we find the doctrine of heat, optics, electricity, and magnetism; and the fourth, besides astronomy and the use of the globes, contains a compendium of the history of aerostation; an account of meteors, including the recent discoveries respecting aeroliths; and a collection of useful tables.

25. Mr Cavallo was also an occasional contributor to several periodical publications, and his critical articles were not in every instance anonymous. He was made a member of the Royal Academy of Naples in 1779, and a fellow of the Royal Society of London in the month of December of the same year.

It is impossible to hesitate in attributing to Mr Cavallo the possession of very considerable powers of mind; but these powers seem to have been of a different nature from those which have distinguished some other individuals, remarkable for the faculty of acute reasoning and brilliant invention, and apparently born to succeed in the highest flights of genius. Mr Cavallo's talents appear to have had more of the imitative character, and to have been rather calculated for the attainment of excellence in the fine arts than in science; but his memory was uncommonly retentive, and his industry seems to have been indefatigable. He used to relate, that when he was first compelled to study Euclid, he felt himself utterly incapable of comprehending the train of argumentation, and he was obliged to get the whole work by heart, both propositions and demonstrations, in order to impress the conclusions strongly on his mind. This expedient answered his purpose very well, as long as the impression lasted; but after some years he had forgotten his task, and he was obliged to go through the whole again in the same manner, still finding it easier to commit the eight entire books, with all the unmeaning letters of reference, to the care of his ever-faithful memory, than to acquire the spirit of the mode of reasoning, and to anticipate the steps of the demonstration; although, after having performed this second labour, he felt himself sufficiently master of the subject. It may be observed that he possessed considerable skill in music; and music was called by the ancients an imitative art, a description which may indeed be somewhat objectionable with regard to the province of the original composer, who creates something altogether unlike what had ever before existed, but which may not improperly be applied to the occupation of a performer; indeed Mr Cavallo, even when his hearing was impaired, still retain-

ed a very correct taste in the execution of vocal music. He possessed also his country's aptitude for the painter's art; and he was particularly happy in cutting out striking likenesses of his acquaintances in paper. The principal object of his life was to collect and arrange the labours of others; and he was so much in the habit of collecting, that he had for many years made it his amusement to collect specimens of the handwriting of eminent persons, which he had extended to an immense number of individuals of different ages and countries. But he was by no means incapable of copying from the great book of nature; and he made, in the course of his various researches, a number of original experiments, well calculated to illustrate particular questions relating to the sciences which he cultivated. In the latter part of his life he had discontinued his attendance at the meetings of the Royal Society, as well as his contributions to the *Transactions;* but he was in the habit of frequenting some other literary conversations, at which he constantly met some of his oldest and kindest friends. A short time before his last illness, he was engaged in some experiments on M. Deluc's perpetual pile of paper, and on the electricity of different specimens of crystals; but he does not appear to have obtained any new results from these investigations. He died at his residence in Wells Street, on the 26th of December 1809, and was buried in St Pancras churchyard, near the tomb of General Paoli, with whom he had long been on terms of the greatest intimacy. (*Literary Memoirs of Living Authors;* Dance's *Collection of Portraits; Gentleman's Magazine,* 1809; *Supplement to the Monthly Magazine,* 1810, p. 86; Aikin's *General Biography,* vol. x.; Chalmers' *Biographical Dictionary,* vol. vii.) (T. Y.)

CAVALLUCI, Antonio, a modern Italian painter of considerable eminence, was born at Sirmoneta in 1752. His works are to be found in the principal cities of northern and central Italy, especially at Pisa and Rome. The best of all his pictures—that representing Venus and Ascanius—is preserved in the Cesarini palace of the latter city. He died in 1795.

CAVALRY (French *cavalerie,* from Latin *caballus* a horse), a body of soldiers who serve on horseback. See Army.

CAVAN, an inland county in the province of Ulster, in Ireland, situated between 53. 43.–54. 7. N. Lat., and 6. 45.–7. 47. W. Long.; bounded N. by Fermanagh and Monaghan, E. by Monaghan and Meath, S. by Meath, Westmeath, and Longford, and W. by Longford and Leitrim. Area 746 square miles, or 477,360 acres, of which 375,473 are arable, 71,918 uncultivated, 7325 in plantations, 502 in towns, and 22,142 under water.

The most ancient geographers describe this and the adjacent counties of Leitrim and Fermanagh as occupied by the tribe of the Erdini. At the period of the English settlement, and for some centuries afterwards, it was known by the name of the Brenny, or O'Reilly's country; and its inhabitants, protected by the nature of the country, long maintained their independence. In 1584 Cavan was formed into a county of Ulster by Sir John Perrott, lord-deputy of Ireland, and subdivided into seven baronies, two of which were assigned to Sir John O'Reilly free of all contributions, and three to other members of the family; while the two remaining baronies, possessed by the septs of Mackernon and Macgauran, and situated in the mountains bordering on O'Rorke's country, were left subject to their ancient tenures and the exactions of their Irish lord, the crown reserving 200 beeves upon the whole county for the lord-deputy's provision. There was also an ancient subdivision, peculiar to this county, into polls, each of which contained about 25 acres. Early in the reign of James I., a commission of inquiry was issued concerning all lands in several counties of Ulster, escheated to the crown by attainder, outlawry, or actual death in rebellion, by which the greater portion of this county was deemed to be vested in the crown, and its exact state thereupon investigated. Under the consequent project for the new plantation of Ulster, the county was distributed among the undertakers, British planters, servitors, natives, and ecclesiastics, &c. &c. The principal English and Scotch families settled in Cavan were the Auchmuties, Bailies, Butlers, Hamiltons, Lamberts, Parsons, and Ridgeways. The county is now divided into eight baronies—Castlerahan, Clanmahon, Clonkee, Loughtee Lower and Upper, Tullygarvey, Tullyhaw, and Tullyhunco. It is almost entirely within the diocese of Kilmore, and contains thirty-six parishes and parts of parishes. In military arrangements it is in the Belfast district; and there are barracks for cavalry at Belturbet, and for infantry at Cavan, where also the staff of the county militia is stationed. The headquarters of the constabulary force, consisting of 419 men and officers, are at Cavan; those of the eight districts, comprising thirty-nine stations, at Cavan, Arva, Ballyjamesduff, Bailieborough, Cootehill, Belturbet, Swanlinbar, and Killeshandra. The revenue police stations are at Belturbet and Bailieborough. The assizes are held at Cavan, where the county prison and the county infirmary are situated. There is a loan fund at Ballyjamesduff, and a savings-bank established in 1830 at Cavan. There are four union workhouses within the county—Bailieborough, Bawnboy, Cavan, and Cootehill; but portions of the county are comprised in the unions of Enniskillen, Granard, and Oldcastle. The amount of property valued under the Act 6th and 7th Will. IV., cap. 84 (Griffith's valuation), is L.247,817, and the net annual value of property rated to the poor is L.248,415. The chief towns are Cavan, pop. (in 1851) 3254, Cootehill 2105, and Belturbet 2054. Prior to the Union it contributed six members to the Irish parliament, two for the county at large, and two for each of the boroughs of Cavan and Belturbet; but since that period it has been represented in the imperial parliament by two county members only. The constituency under 13th and 14th Vict., cap. 69, in 1851, numbered 3850.

The remains of antiquity in this county are few in number and unimportant in interest. They consist of cairns, raths, and the ruins of small castles.

The surface of the country is uneven, consisting of hill and dale, without any great extent of level ground, but only in its northern extremity attaining a mountainous elevation. The barony of Tullaghagh, bordering on Fermanagh, a wild dreary mountain district, known as the kingdom of Glan or Glangavlin, contains the highest land in the county, called Slieve Russel. In the same barony is Quilca mountain, the place of inauguration for the Macguires, chieftains of Fermanagh, held in great veneration by the peasantry, in connection with legends and ancient superstitions. The remainder of the county is occasionally not deficient in wood, and adorned by numerous lakes, generally of small dimensions, but of much interest for their picturesque beauty, more especially Lough Oughter, which lies between the towns of Cavan and Killeshandra. Though not of very imposing size, the irregularity of its form, the large and beautiful islands imbedded in its waters, and the many deep recesses studded with overhanging woods that wind among its high banks, produce a rich variety of prospect. The water of the lakes is generally very clear, and they abound with fish. The chief river in the county is the Erne, which originates in the Lake of Scrabby, one of the minor sheets of water communicating with Lough Gawnagh, on the borders of Longford. The river takes a northerly direction by Killeshandra and Belturbet, being enlarged during its course by the Annalee and other smaller streams, and finally enters Lough Erne near the northern limit of the county. The other waters, consisting of numerous lakes and their connecting streams, are mostly tributary to the Erne. The great river Shannon is by some

supposed to have its source in a copious spring called the Shannon Pot, at the foot of the Cuilagh mountain, in the barony of Tullaghagh. The Blackwater, a tributary to the Boyne, also rises in this county, near Bailieborough. The main roads are kept in good order, but the cross roads are frequently ill planned and in bad condition. The line of railway in progress (1854) from Mullingar to Cavan and Enniskillen will pass through the county.

The climate of this county is cold but salubrious; the dampness, arising from its numerous lakes and the nature of the soil, being much dispelled by the boisterous weather which frequently prevails, more especially in the higher districts.

The south-eastern portion of Cavan rests upon clay-slate, and the remainder of the county upon the carboniferous limestone formation. A rich iron ore was formerly raised from Quilca mountain. The ore was smelted at Swanlinbar, but the works were ultimately relinquished in consequence of the failure of timber for fuel. Indications of lead, silver, and sulphur have been observed; and fullers' earth, pipe-clay, potters' clay, and brick-clay are frequently met with in Tullaghagh barony, in which there are also indications of coal. Several mineral springs exist in this county, the chief of which is near the once-frequented village of Swanlinbar. Its constituents are carbonic, muriatic, and sulphuric acids, combined with soda and a little lime. It acts as a diuretic, and is considered serviceable in diseases of the skin, kidneys, and bladder, and also in gout. In the neighbourhood of Belturbet, near the small lake of Annagh, is a carbonated chalybeate, resembling the crescent well of Harrowgate, beneficially used in cases of relaxation and debility, and especially in dyspepsia. There are several other springs of less importance: and the small Lough Leighs, or Lough-an-Leighaghs, which signifies the healing lake, on the summit of a mountain between Bailieborough and Kingscourt, is celebrated for its antiscorbutic properties. Its waters are used for drinking and bathing; but the most beneficial effects are said to be produced by the local application of the tenacious mud raised from the bottom of the lake. The level of the lake never varies. It has no visible supply nor vent for its discharge; neither is it ever frozen during the severest winters. The water at the surface is clear; but within a foot downwards it becomes clogged with mud, which thickens as the depth increases. The mud is drawn up for medicinal purposes by means of a pole with a hay rope twisted round it, to which the mud adheres, exhibiting a greasy shining surface like tar.

The chief manufacture is the weaving and bleaching of linen, which is carried on by the peasantry, in combination with agricultural occupations; but the combination is not to the advantage of either branch. There are also extensive distilleries. Illicit distillation was formerly carried on to a great extent, the lakes affording great facilities for its practice. The grain was steeped in them, and the portable and cheap apparatus employed was set up close to their shores, so that in case of alarm the whole could be flung into the water at a moment's notice, and remain concealed until raised again for future service.

The soil is generally a stiff wet clay, cold and spongy, but capable of much improvement by drainage, for which its undulating surface affords facilities of which little advantage has been taken. Agriculture is in a backward state, the farms being generally small, the tenures short and unsatisfactory, and the modes of culture generally defective. In the mountainous parts, where the land is chiefly under grazing, the farms are more extensive. The number of holdings in 1851 was 21,495, of which 2012 were of less than 5 acres, 9100 between 5 and 15 acres, 6546 between 15 and 30 acres, 3081 above 30 acres, and the remaining 756 not exceeding one acre. The extent of land under crops in 1847 was 158,366 acres, and in 1853, 176,591, viz.—wheat, 650; oats, 89,929; barley, bere, rye, pease and beans, 2883; potatoes, 27,734; turnips, 4528; mangel-wurzel, vetches, and other green crops, 3840; flax, 12,106; meadow and clover, 34,921. The culture of potatoes and flax has increased during the last few years, but other crops show little variation; that of wheat, however, as in the rest of Ireland, being on the decline. The live stock contained within the county in 1852 amounted to 10,043 horses, 9338 mules and asses, 92,690 cattle, 16,167 sheep, 24,715 pigs, 14,024 goats, 328,241 poultry, of the total value of L.757,943. The estimated value of the live stock in 1841 was L.492,506. The soil in those districts not well adapted for tillage is peculiarly favourable for trees. The woods were formerly very considerable, and the timber found in the bogs is of large dimensions; but plantations are now chiefly found in demesnes, where they are extensive; and the bareness of the landscape, too long a glaring drawback on the natural beauties of the county, is gradually becoming less observable.

There being but three towns in the county containing more than 2000 inhabitants, the population is chiefly rural, and increased at the rate of 17 per cent. between 1821–31, and 7 per cent. between 1831–41; since which period the numbers have rapidly declined, so that the decrease between 1841–51 has amounted to 28 per cent. The following are the numbers according to the census returns:—

Year	No. of Souls.	Increase.	Decrease.
1821	195,076	..	...
1831	227,933	32,857	...
1841	243,158	15,225	...
1851	174,071	...	69,087

The population of the county of Cavan is less mixed in race than in most parts of Ulster, being generally of Celtic extraction. The dwellings of the peasantry are miserable in appearance, and form a striking contrast to the seats of the resident gentry, which are numerous and elegant. Lord Farnham has a noble mansion at Cavan; and at Kilmore is the bishop's palace, a modern building.

In 1851 there were 174 national schools in operation, attended by 15,097 children, 8085 males and 7012 females. At the same period the state of education among the population exceeding the age of five years was as follows:—

	Rural districts.	Civic districts.	Total.	Proportion per cent. in 1851.	Proportion per cent. in 1841.
Could read and write	16,079	1234	17,313	22	14
Could read only	20,502	829	21,331	27	26
Could neither read nor write	38,791	1453	40,244	51	60

About two-thirds of the entire population are Roman Catholics; the remaining third belong to the Established church, with the exception of a small number of Dissenters.

Cavan, the capital of the county of the same name, and previous to the Union a parliamentary borough, has little to command special notice. It is situated near the centre of the county, on one of the tributary streams of the Annalee river, in a large valley surrounded on every side by elevated ground, with picturesque environs, adorned by the mansions and demesnes of Lord Farnham and the Bishop of Kilmore. The town, which in 1851 contained 3254 inhabitants, is of unpretending and rather humble appearance. The court-house, erected at an expense of L.11,000, is elegant in its proportions and convenient in its internal arrangements. The parish church, built on an elevated site, is also a graceful structure. The most conspicuous building is the grammar-school, founded by Charles I. It was rebuilt in 1819, at an expense of L.9000, on an eminence overlooking one of the main entrances into the town. It is a large and handsome edifice, capable of accommodating one hundred resident pupils, but has never yet contained more than one-fourth of that number. The master enjoys a salary of L.300 per annum, besides fees from

pupils, &c., and the use of ten acres of land adjoining the house. The other public buildings are the Roman Catholic chapel and Dissenters' meeting-houses; the county gaol and infirmary; a barrack; and the union workhouse. Cavan has still some linen trade, and a considerable retail business is transacted in the town, which was incorporated by a royal charter of the 8th of James I., now extinct. It is the seat of a presbytery of the General Assembly of the Presbyterian church in Ireland; but the great majority of the inhabitants are Roman Catholics. A monastery of Dominican friars, founded by O'Reilly chieftain of the Brenny, formerly existed here, and became the burial place of the celebrated Irish general, Owen O'Neal, who died as is supposed by poison, in 1649, at Cloughoughter. This monastery, and all the other antiquities of the town, have been swept away during the violent and continuous feuds to which the country has been subjected. Even so late as the year 1690 the chief portion of the town was burned by the Enniskilleners under General Wolsey. Cavan is distant 70 miles N.W. by N. from Dublin. (H. S—R.)

CAVANILLES, Antonio Jose, a Spanish ecclesiastic, who devoted himself with great assiduity to the study of botany, and has published several important works, was born in 1745, at Valencia. He received his first education among the Jesuits in that university, and he ever afterwards retained the urbanity of character and manners characteristic of that celebrated order of men. He early devoted himself to the studies of divinity and philosophy, and was distinguished for diligence and ability, not only in these pursuits, but in the mathematics, history, and belles-lettres. He afterwards removed to Murcia, where he acquired so much credit that he was chosen by the Duke de l'Infantado to superintend the education of his sons. He accompanied them to Paris in 1777, where he resided twelve years, adding to his various information, and particularly cultivating the science of botany, with all the aids which that celebrated capital was so well calculated to afford. Here he was more particularly associated with the famous Jussieu, and the pupils of his school. From the Linnæan botanists of Paris he was a good deal estranged; yet he acquired a great inclination towards the Swedish school, and imbibed many of its good principles.

The first publication of the Abbé Cavanilles was in French, entitled *Observations sur l'article "Espagne" de la Nouvelle Encyclopédie*. This pamphlet contained a defence of his country against what appeared to him an unfair attack upon it; but we know not the particular subjects of the discussion.

He soon afterwards devoted himself to a study which promised him a less thorny path. In 1785 he published at Paris his first *Dissertation upon Monadelphous Plants*, a Latin 4to, containing the species of the genus *Sida*, with some plants nearly related thereto. The plates, uncoloured, were executed from his own drawings; as were those of the rest of his numerous publications. The specimens delineated in this first essay were too small and imperfect. In that respect his following dissertations, making ten in all, have a considerable superiority. His subsequent figures were also better engraved. The descriptions are full and correct; the new species numerous; and the specific characters tolerably classical, though not quite uncontaminated by the feebleness and ambiguity of the French school. This work, in its beginning, not being received by the Linnæan botanists of Paris, and especially by L'Héritier, with any respectful attention, the author, in an evil hour, was induced to complain, in the *Journal de Paris*, of neglect and injustice. L'Héritier had not noticed the book in his *Stirpes Novæ;* had published the same plants by different names, without citing Cavanilles; and had even antedated some of his own *Fasciculi*, in order to conceal, as it appeared, this literary incorrectness. His reply could not, in the opinion of unprejudiced witnesses, clear him of illiberal conduct; though it is very certain he neither did nor could borrow anything from Cavanilles. It would have been better to have declared the truth, that his own plates were already engraved with different names, or that he had at least chosen such as seemed to him preferable. The ninth and tenth *fasciculi* of Cavanilles, on the *Monadelphous* Plants, were indeed published at Madrid, to which place the author returned in 1790. The number of plates in the whole work are 296, many of which, especially in the earlier part, contain several species. It cannot be denied that the merit of this work kept increasing as it advanced. The abilities of the writer gained strength by exercise, and his knowledge was enriched by experience. He is charged with admitting as *monadelphous* too many plants, the union of whose stamens is very light or uncertain; a more real fault is, the usual one of too great and artificial a subdivision of genera.

Soon afterwards the Abbé Cavanilles began a larger and more comprehensive publication in folio, entitled *Icones et Descriptiones Plantarum quæ aut sponte in Hispania crescunt, aut in Hortis hospitantur*. The first volume appeared in 1791, containing 100 plates, with ample descriptions. It was followed by five more, of equal size and merit, the last of which came out in 1801. The whole work is enriched with critical remarks, and with much economical, as well as what may be called picturesque and sentimental matter respecting many native Spanish plants. The exotic part of these volumes is derived from the highly valuable and novel discoveries of the Spaniards in Mexico, Peru, and Chili, and the acquisitions of some voyagers to New Holland and the Philippine Islands. Hence numerous very fine plants, originally discovered by our own celebrated circumnavigators, but unfortunately not yet published by them, have first been made known in the pages of Cavanilles.

In the course of the botanical tours of our author, he collected materials for a general *History of the Kingdom of Valencia*, which appeared in 1795, in Spanish, making two volumes. This work, which we have never seen, is said to be rich, not only in what relates to the three kingdoms of nature, but likewise in statistical and antiquarian information.

Having in June 1801 been intrusted with the directorship of the royal garden at Madrid, he published in 1802 another work in his native tongue, containing the characters and descriptions of the plants demonstrated in his public botanical lectures. To these is prefixed an exposition of the elementary principles of the science, together with explanations of botanical terms. Cavanilles was also a frequent and important contributor to the periodical work entitled *Anales de Ciencias Naturales*, published at Madrid. Some observations of his, translated from this journal, may be found in Dr Sim's and Mr König's *Annals of Botany*, vol. i. 409. The first of these indeed, relative to certain seemingly lenticular bodies, supposed to have an important share in the impregnation of ferns and mosses, he has himself contradicted, as arising from an optical deception. His candid avowal of this, in a letter to Dr Schwartz, is published in volume second of the said *Annals*, p. 587. We think him also mistaken in the true stigma of the *Iris*, his opinion being sufficiently refuted by those of Kolreuter and Sprengel, given in a note, in the very place just quoted; nor is his idea of the stamens of certain *Asclepiadeæ* correct. If he errs, however, he errs with great authorities.

The subject of our present memoir undoubtedly excelled more in practical observation than in physiological speculation. He is said to have prepared, and partly printed, the first volume of a *Hortus Matritensis*, being a sort of sequel to his *Icones;* for it was intended to contain not merely the figures and descriptions of curious or new plants from ethgarden, but also of rare dried specimens from the museum

at Madrid. This work was cut short by his death, in May 1804, in the fifty-ninth year of his age. (J. E. S.)

CAVE (Latin *cavea*), a cavern, either below the surface of the ground, or in the face of a rock or hill. The primitive inhabitants of the earth probably dwelt in caves before the art of building was practised; and caves long continued to be the proper habitations of shepherds. In some countries, at this day, caves in the face of rocks, and even below the ground, during winter in high latitudes are used as habitations. The ancient city of Petra may be said to be a city of artificial caves. These are cut in the face of the sandstone rock; and from their great number and extent, some of these were, in all probability, human habitations. In Genesis xix., we read that when Lot went up out of Zoar, "he dwelt in a cave, he and his two daughters." The primitive method of burial also was to deposit the bodies in caves; and this custom appears to have been the origin of catacombs. Among the Romans, *antra* or caverns were consecrated to nymphs, who were there worshipped, as other divinities in temples. The grotto of the nymph Egeria is still shown at Rome. The Persians also worshipped their deity Mithras in a natural cavern, consecrated for the purpose by Zoroaster. See GROTTO.

CAVE, *Edward*, a celebrated printer, born in 1691. He was placed by his father, who was a shoemaker at Rugby, at the free school of that place, which was then in high reputation, but he was soon after withdrawn and appointed clerk to a collector of the excise.

The drudgery and insolence to which he was subjected quickly disgusted him, and after having been engaged for some time by a timber-merchant in London, he was finally bound apprentice in the printing-office of Mr Collins. In two years he attained so much skill in his art, that he was sent to conduct a printing-house at Norwich, and publish a weekly paper. In this undertaking he met with some opposition, which produced a public controversy, and procured young Cave the reputation of a writer. On the death of his master he married, and eked out the emoluments of a small place in the post-office by occasional contributions to the periodical literature. He held for a short time the office of clerk of the franks, but his rigour in checking abuses soon produced his dismissal. He now embarked the capital which he had acquired in the publication of the *Gentleman's Magazine*, a periodical which procured a fortune for the projector, and survived almost all its competitors.

Cave now began to aspire to popularity as a patron of poets, to whom he proposed subjects and offered prizes. His parsimony, however, led him to underestimate the amount of remuneration required, and the scheme accordingly proved a failure. It must never be forgotten, however, that Cave was the first to give literary employment to Samuel Johnson when he arrived in London an unknown youth from the country.

Mr Cave continued to improve his magazine, and had the satisfaction of seeing its success proportionate to his diligence, till 1751, when his wife died of an asthma. At first he did not seem much affected by her death; but in a few days he became feverish, and lost his appetite. After having lingered for about two years, he was seized with a diarrhœa by drinking acid liquors; and afterwards falling into a kind of lethargic insensibility, he died on the 10th of January 1754, having concluded the twenty-third annual collection of his magazine.

CAVE, *Dr William* (1637–1713), a learned English divine, educated in St John's College, Cambridge, and successively minister of Hasely in Oxfordshire, of All-Hallows the Great of Islington in London, and of Isleworth in Middlesex. He became chaplain to Charles II., and in 1684 was installed as a canon of Windsor. The two works on which his reputation principally rests are, the *Apostolici*, or History of the Apostles and Fathers in the three first centuries of the Church, and *Scriptorum Ecclesiasticorum Historia Literaria*; in regard to both of which he was drawn into controversy with Le Clerc, who was then writing his *Bibliothèque Universelle*, and who accused him of partiality. Besides these, he wrote *Primitive Christianity, or Religion of the Ancient Christians, &c.; Tabulæ Ecclesiasticæ, Antiquitates Apostolicæ, A Dissertation concerning the Government of the Ancient Church, &c.; Ecclesiastici, or History of the Fathers of the fourth century;* and a work entitled *Chartophylax Ecclesiasticus*, which is an abridgment of the *Historia Literaria.*

CAVEDONE, JACOPO (1577–1660), an eminent Italian painter, was educated in the school of the Caracci, and under them painted in the churches of Bologna. His principal works are, the *Adoration of the Magi*, the *Four Doctors*, and *The Last Supper.*

CAVENDISH, HENRY, a great and justly celebrated chemist, natural philosopher, and astronomer; son of Lord Charles Cavendish, and grandson of William, second duke of Devonshire; born the 10th of October 1731, at Nice, where his mother, Lady Anne Grey, daughter of Henry duke of Kent, had gone, though ineffectually, for the recovery of her health.

Of a man whose rank among the benefactors of science and of mankind is so elevated as that of Cavendish, we are anxious to learn all the details both of intellectual cultivation and of moral character which the labours of a biographer can discover and record. Little, however, is known respecting his early education. He was for some time at Newcombe's school, an establishment of considerable reputation at Hackney, and he afterwards went to Cambridge; but it is probable that he acquired his taste for experimental investigation in a great measure from his father, who was in the habit of amusing himself with meteorological observations and apparatus, and to whom we are indebted for a very accurate determination of the depression of mercury in barometrical tubes, which has been made the basis of some of the most refined investigations of modern times. "It has been observed," says M. Cuvier, "that more persons of rank enter seriously into science and literature in Great Britain than in other countries; and this circumstance may naturally be explained from the constitution of the British government, which renders it impossible for birth and fortune alone to attain to distinction in the state without high cultivation of mind; so that amidst the universal diffusion of solid learning which is thus rendered indispensable, some individuals are always found who are more disposed to occupy themselves in the pursuit of the eternal truths of nature, and in the contemplation of the finished productions of talent and genius, than in the transitory interests of the politics of the day." Mr Cavendish was neither influenced by the ordinary ambition of becoming a distinguished statesman, nor by a taste for expensive luxuries or sensual gratifications; so that, enjoying a moderate competence during his father's life, and being elevated by his birth above all danger of being despised for want of greater affluence, he felt himself exempted from the necessity of applying to any professional studies, of courting the approbation of the public either by the parade of literature or by the habits of conviviality, or of ingratiating himself with mixed society by the display of superficial accomplishments. It is difficult to refrain from imagining that his mind had received some slight impression from the habitual recurrence to the motto of his family; the words *cavendo tutus* must have occurred perpetually to his eyes; and all the operations of his intellectual powers exhibit a degree of *caution* almost unparalleled in the annals of science; for there is scarcely a single instance in which he had occasion to retrace his steps or to recal his opinions. In 1760 he became a fellow of the Royal Society, and continued

 for almost fifty years to contribute to the *Philosophical Transactions* some of the most interesting and important papers that have ever appeared in that collection, expressed in language which affords a model of concise simplicity and unaffected modesty, and exhibiting a precision of experimental demonstration, commensurate to the judicious selection of the methods of research, and to the accuracy of the argumentative induction; and which have been considered, by some of the most enlightened historians, as having been no less instrumental in promoting the further progress of chemical discovery, by banishing the vague manner of observing and reasoning that had too long prevailed, than by immediately extending the bounds of human knowledge with respect to the very important facts which are first made public in these communications.

1. *Three Papers, containing Experiments on Factitious Air. Phil. Trans.* 1766, p. 141. It had been observed by Boyle, that some kinds of air were unfit for respiration; and Hook and Mayow had looked still farther forwards into futurity with prophetic glances, which seem to have been soon lost and forgotten by the inattention or want of candour of their successors. Hales had made many experiments on gases, but without sufficiently distinguishing their different kinds, or even being fully aware that fixed air was essentially different from the common atmosphere. Sir James Lowther, in 1733, had sent to the Royal Society some bladders filled with coal damp, which remained inflammable for many weeks; little imagining the extent of the advantages which were one day to result to his posterity from the labours of that society, by the prevention of the fatal mischiefs which this substance so frequently occasioned. Dr Seip had soon afterwards suggested that the gas which stagnated in some caverns near Pyrmont was the cause of the briskness of the water; Dr Brownrigg of Whitehaven had confirmed this opinion by experiments in 1741; and Dr Black, in 1755, had explained the operation of this fluid in rendering the earths and alkalies mild. Such was the state of pneumatic chemistry when Mr Cavendish began these experimental researches. He first describes the apparatus now commonly used in processes of this kind, a part of which had been before employed by Hales and others, but which he had rendered far more perfect by the occasional employment of mercury. He next relates the experiments by which he found the specific gravity of inflammable air to be about $\frac{1}{11}$th of that of common air, whether it was produced from zinc or otherwise: first weighing a bladder filled with a known bulk of the gas, and then in a state of collapse; and also examining the loss of weight during the solution of zinc in an acid, having taken care to absorb all the superfluous moisture of the gas by means of dry potass. He also observed, that the gas obtained during the solution of copper in muriatic acid was rapidly absorbed by water, but he did not inquire further into its nature. The second paper relates to fixed air, which was found to undergo no alteration in its elasticity when kept a year over mercury; to be absorbed by an equal bulk of water, or of olive oil, and by less than half its bulk of spirit of wine; to exceed the atmospheric air in specific gravity by more than one half, and to render this fluid unfit for supporting combustion, even when added to it in the proportion of 1 to 9 only. Mr Cavendish ascertained the quantity of this gas contained in marble and in the alkalies; but his numbers fell somewhat short of those which have been determined by later experiments. He also observed the solubility of the supercarbonate of magnesia. In the third part, the air produced by fermentation and putrefaction is examined. Macbride had shown that a part of it was fixed air; and our author finds that sugar and water, thrown into fermentation by yeast, emit this gas, without altering the quantity or quality of the common air previously contained in the vessel, which retains its power of exploding with hydrogen, exactly like common air. He also shows that the gas thus emitted is identical with the fixed air obtained from marble; and that the inflammable air extricated during putrefaction resembles that which is procured from zinc, although it appears to be a little heavier.

2. *Experiments on Rathbone Place Water. Phil. Trans.* 1767, p. 92. In this paper Mr Cavendish shows the solubility of the supercarbonate of lime, which is found in several waters about London, and is decomposed by the process of boiling, the simple carbonate being deposited in the form of a crust. The addition of pure lime water also causes a precipitation of a greater quantity of lime than it contains. These conclusions are confirmed by synthetical experiments, in which the supercarbonate is formed, and remains in solution.

3. *An Attempt to explain some of the principal Phenomena of Electricity by means of an Elastic Fluid. Phil. Trans.* 1771, p. 584. Our author's theory of electricity agrees with that which had been published a few years before by Æpinus, but he has entered more minutely into the details of calculation; showing the manner in which the supposed fluid must be distributed in a variety of cases, and explaining the phenomena of electrified and charged substances, as they are actually observed. There is some degree of unnecessary complication, from the great generality of the determinations; the law of electric attraction and repulsion not having been at that time fully ascertained, although Mr Cavendish inclines to the true supposition, of forces varying inversely as the square of the distance. This deficiency he proposes to supply by future experiments, and leaves it to more skilful mathematicians to render some other parts of the theory still more complete. He probably found, that the necessity of the experiments which he intended to pursue was afterwards superseded by those of Lord Stanhope and M. Coulomb; but he had carried the mathematical investigation somewhat farther at a later period of his life, though he did not publish his papers; an omission, however, which is the less to be regretted, as M. Poisson, assisted by all the improvements of modern analysis, afterwards treated the same subject in a very masterly manner. The acknowledged imperfections in some parts of Mr Cavendish's demonstrative reasoning, have served to display the strength of a judgment and sagacity still more admirable than the plodding labours of an automatical calculator. One of the corollaries seems at first sight to lead to a mode of distinguishing positive from negative electricity, which is not justified by experiment; but the fallacy appears to be referable to the very comprehensive character of the author's hypothesis, which requires some little modification to accommodate it to the actual circumstances of the electric fluid, as it must be supposed to exist in nature.

4. *A Report of the Committee appointed by the Royal Society to consider of a Method for securing the Powder Magazine at Purfleet. Phil. Trans.* 1773, p. 42. *Additional Letter*, p. 66. Mr Cavendish, and most of his colleagues on the committee, recommended the adoption of pointed conductors; Mr Wilson protested, and preferred blunt conductors; but the committee persisted in their opinion. Later experiments, however, have shown that the point in dispute between them was of little moment.

5. *An Account of some Attempts to imitate the Effects of the Torpedo by Electricity. Phil. Trans.* 1776, p. 196. The peculiarity of these effects is shown to depend in some measure on the proportional conducting powers of the substances concerned, and on the quantity of electricity, as distinguished from its intensity. Iron is found to conduct 400 million times as well as pure water, and sea water 720

times as well; and the path chosen by the electric fluid depending on the nature of all the substances within its reach, an animal not immediately situated in the circuit will often be affected, on account of the facility with which animal substances in general conduct the fluid. The shock of a torpedo, producing a strong sensation, but incapable of being conveyed by a chain, was imitated by the effect of a weak charge of a very large battery; and an artificial torpedo of wood being made part of the circuit, the shock diffused itself very perceptibly through the water in which it was placed; but the experiment succeeded better when the instrument was made of wet leather, which conducts rather better than wood, the battery being more highly charged, in proportion to the increase of conducting power.

6. *An Account of the Meteorological Instruments used at the Royal Society's House. Phil. Trans.* 1776, p. 375. Of the thermometers it is observed, that they are adjusted by surrounding the tubes with wet cloths or with steam, and barely immersing the bulbs in the water; since a variation of two or three degrees will often occur, if these precautions are neglected. For the correction of the heights of barometers, we have Lord Charles Cavendish's table of the depression arising from capillary action. The variation compass was found to exhibit a deviation from the meridian 15′ greater in the house of the Royal Society than in an open garden in Marlborough Street; there was also a mean error of about 7′ in the indications of the dipping needle; but it was difficult to ascertain the dip, without being liable to an irregularity which often amounted to twice as much.

7. *Report of the Committee appointed to consider of the best Method of adjusting Thermometers. Phil. Trans.* 1777, p. 816. This paper is signed by Mr Cavendish and six other members, but it is principally a continuation of the preceding. It contains very accurate rules for the determination of the boiling point, and tables for the correction of unavoidable deviations from them; establishing 29·8 inches as the proper height of the barometer for making the experiment if only steam be employed, and 29·5 if the ball be dipped in the water; but, with all precautions, occasional variations of half a degree were found in the results.

8. *An Account of a New Eudiometer. Phil. Trans.* 1783, p. 106. Mr Cavendish was aware of the great difference in the results of eudiometrical experiments with nitrous gas, or nitric oxide, according to the different modes of mixing the elastic fluids; and he justly attributes them to the different degrees of oxygenization of the acid that is formed. But he found that when the method employed was the same, the results were perfectly uniform; and he ascertained in this manner that there was no sensible difference in the constituent parts of the atmosphere under circumstances the most dissimilar; the air of London, with all its fires burning in the winter, appearing equally pure with the freshest breezes of the country. He also observed the utility of the sulphurets of potass and of iron for procuring phlogisticated air; but he does not seem to have employed them as tests of the quantity of this gas contained in a given mixture.

9. *Observations on Mr Hutchins's Experiments for determining the degree of Cold at which Quicksilver freezes. Phil. Trans.* 1783, p. 303. In experiments of this kind many precautions are necessary, principally on account of the contraction of the metal at the time of its congelation, which was found to amount to about $\frac{1}{23}$d of its bulk; and the results which had been obtained were also found to require some corrections for the errors of the scales, which reduced the degree of cold observed to 39° below the zero of Fahrenheit, or 71° below the freezing point, answering to — 39·4° of the centesimal scale. In speaking of the evolution of heat during congelation, he calls it "generated" by the substances; and observes, in a note, that Dr Black's hypothesis of capacities depends "on the supposition that the heat of bodies is owing to their containing more or less of a substance called the matter of heat; and as" he thinks "Sir Isaac Newton's opinion, that heat consists in the internal motion of the particles of bodies, much the most probable," he chooses "to use the expression heat is generated," in order to avoid the appearance of adopting the more modern hypothesis; and this persuasion of the non-existence of elementary heat he repeats in his next paper. It is remarkable that one of the first of Sir Humphry Davy's objects, at the very beginning of his singularly brilliant career of refined investigation and fortunate discovery, was the confirmation of this almost forgotten opinion of Mr Cavendish; and for this purpose he devised the very ingenious experiment of melting two pieces of ice by their mutual friction in a room below the freezing temperature, which is certainly incompatible with the common doctrine of caloric, unless we admit that caloric could have existed in the neighbouring bodies in the form of cold, or of something else that could be converted into caloric by the operation; and this transmutation would still be nearly synonymous with generation in the sense here intended. However this may be, it is certain that, notwithstanding all the experiments of Count Rumford, Dr Haldalt, and others, Sir Humphry was less successful in persuading his contemporaries of the truth of Mr Cavendish's doctrine of heat, than in establishing the probability of his opinions respecting the muriatic acid.

10. *Experiments on Air. Phil. Trans.* 1784, p. 119. This paper contains an account of two of the greatest discoveries in chemistry that have ever yet been made public; the composition of water, and that of the nitric acid. The author first establishes the radical difference of hydrogen from nitrogen or azote; he then proceeds to relate his experiments on the combustion of hydrogen with oxygen, which had partly been suggested by a cursory observation of Mr Warltire, a lecturer on natural philosophy, and which prove that pure water is the result of the process, provided that no nitrogen be present. These experiments were first made in 1781, and were then mentioned to Dr Priestley; and when they were first communicated to Lavoisier, he found some difficulty in believing them to be accurate. The second series of experiments demonstrates, that when phlogisticated air, or nitrogen, is present in the process, some nitric acid is produced; and that this acid may be obtained from atmospheric air, by the repeated operation of the electrical spark.

It has been supposed by one of Mr Cavendish's biographers, that if Mr Kirwan, instead of opposing, had adopted his chemical opinions, "he would never have been obliged to yield to his French antagonists, and the antiphlogistic theory would never have gained ground." But in this supposition there seems to be a little of national prejudice. Mr Cavendish by no means dissented from the whole of the antiphlogistic theory; and in this paper he has quoted Lavoisier and Scheele in terms of approbation, as having suggested the opinion "that dephlogisticated and phlogisticated air are quite distinct substances, and not differing only in their degree of phlogistication, and that common air is a mixture of the two." He afterwards mentions several memoirs of Lavoisier in which phlogiston is entirely discarded; and says that "not only the foregoing experiments, but most other phenomena of nature, seem explicable as well, or nearly as well, upon this as upon the commonly believed principle of phlogiston;" and after stating a slight conjectural objection, derived from the chemical con-

stitution of vegetables, he proceeds finally to observe, that "Lavoisier endeavours to prove that dephlogisticated air is the acidifying principle." This is no more than saying that acids lose their acidity by uniting to phlogiston, which, with regard to the nitrous, vitriolic, phosphoric, and arsenical acids, is certainly true; and probably with regard to the acid of sugar; "but as to the marine acid, and acid of tartar, it does not appear that they are capable of losing their acidity by any union with phlogiston;" and the acids of sugar and tartar become even less acid by a further dephlogistication. It is obvious that this argument amounts only to an exception, and not to a total denial of the truth of the theory. M. Cuvier has even asserted that the antiphlogistic theory derived its first origin from one great discovery of Mr Cavendish, that of the nature of hydrogen gas, and owed its complete establishment to another, that of the composition of water; but it would be unjust to deny to Lavoisier the merit of considerable originality in his doctrines respecting the combinations of oxygen; and however he may have been partly anticipated by Hook and Mayow, it was certainly from him that the modern English chemists immediately derived the true knowledge of the constitution of the atmosphere, which they did not admit without some hesitation, but which they did ultimately admit when they found the evidence irresistible. On the other hand, it has been sufficiently established, since Mr Cavendish's death, by the enlightened researches of the most original of all chemists, that Lavoisier had carried his generalization too far; and it must ever be remembered, to the honour of Mr Cavendish, and to the credit of this country, that we had not all been seduced, by the dazzling semblance of universal laws, to admit facts as demonstrated which were only made plausible by a slight and imperfect analogy.

11. *Answer to Mr Kirwan's Remarks upon the Experiments on Air. Phil. Trans.* 1784, p. 170. Mr Kirwan, relying on the results of some inaccurate experiments, had objected to those conclusions which form the principal basis of the antiphlogistic theory. Mr Cavendish repeated such of these experiments as seemed to be the most ambiguous, and repelled the objections; showing, in particular, that when fixed air was derived from the combustion of iron, it was only to be referred to the plumbago shown by Bergmann to exist in it, which was well known to be capable, in common with other carbonaceous substances, of affording fixed air.

12. *Experiments on Air. Phil. Trans.* 1785, p. 372. The discovery of the composition of the nitric acid is here further established; and it is shown that the whole, or very nearly the whole, of the irrespirable part of the atmosphere is convertible into this acid when mixed with oxygen, and subjected to the operation of the electric spark; the fixed air sometimes obtained during the process being wholly dependent on the presence of some organic substances.

13. *An Account of Experiments made by Mr John Macnab, at Henley House, Hudson's Bay, relating to Freezing Mixtures. Phil. Trans.* 1786, p. 241. From these experiments Mr Cavendish infers the existence of two distinct species of congelation in mixed liquids, which he calls the aqueous and spirituous congelations, and of several alternations of easy and difficult congelation when the strength is varied, both in the case of the mineral acids and of spirit of wine. The greatest degree of cold obtained in these experiments was — $78\frac{1}{2}°$.

14. *An Account of Experiments made by Mr John Macnab, at Albany Fort, Hudson's Bay. Phil. Trans.* 1788, p. 166. The points of easy congelation are still further investigated, and illustrated by comparison with Mr Keir's experiments on the sulphuric acid. It was found that the nitric acid was only liable to the aqueous congelation, unless it was strong enough to dissolve one fourth of its weight of marble; and that it had a point of easy congelation, when it was capable of dissolving $\frac{415}{1000}$, the frozen part exhibiting, in other cases, a tendency to approach to this standard. Mr Keir had found that sulphuric acid of the specific gravity 1·78 froze at 46°; and that it had another minimum when it was very highly concentrated.

15. *On the Conversion of a Mixture of Dephlogisticated and Phlogisticated Air into Nitrous Acid, by the Electric Shock. Phil. Trans.* 1788, p. 261. Some difficulties having occurred to the Continental chemists in the repetition of this experiment, it was exhibited with perfect success, by Mr Gilpin, to a number of witnesses. This was an instance of condescension which could scarcely have been expected from the complete conviction which the author of the discovery must have felt of his own accuracy, and of the necessity of the establishment of his discovery, when time should have been afforded for its examination.

16. *On the Height of the Luminous Arch which was seen on Feb.* 23, 1784. *Phil. Trans.* 1790, p. 101. Mr Cavendish conjectures that the appearance of such arches depends on a diffused light, resembling the aurora borealis, spread into a flattened space contained between two planes nearly vertical, and only visible in the direction of its breadth, so that they are never seen at places far remote from the direction of the surface; and hence it is difficult to procure observations sufficiently accurate for determining their height upon so short a base; but in the present instance there is reason to believe that the height must have been between fifty-two and seventy-one miles.

17. *On the Civil Year of the Hindoos, and its Divisions, with an Account of three Almanacs belonging to Charles Wilkins, Esq. Phil. Trans.* 1792, p. 383. The subject of this paper is more intricate than generally interesting; but it may serve as a specimen of the diligence which the author employed in the investigation of every point more or less immediately connected with his favourite objects. The month of the Hindus is lunar in its duration, but solar in its commencement; and its periods are extremely complicated, and often different for different geographical situations. The day is divided and subdivided sexagesimally. The date of the year, in the epoch of the Kaly Yug, expresses the ordinal number of years elapsed, as it is usual with our astronomers to reckon their days; so that the year 100 would be the beginning of the second century, and not the 100th year, or the end of the first century, as in the European calendar; in the same manner as, in astronomical language, 1817 December 31d. 18h. means six o'clock in the morning of the 1st of January 1818.

18. *Experiments to determine the Density of the Earth. Phil. Trans.* 1798, p. 469. The apparatus with which this highly important investigation was conducted had been invented and constructed many years before by the reverend John Michell, who did not live to perform the experiments for which he intended it. Mr Cavendish, however, by the accuracy and perseverance with which he carried on a course of observations of so delicate a nature, as well as by the skill and judgment with which he obviated the many unforeseen difficulties that occurred in its progress, and determined the corrections of various kinds which it was necessary to apply to the results, has deserved no less gratitude from the cultivators of astronomy and geography than if the idea had originally been his own. The method employed was to suspend by a vertical wire a horizontal bar, having a leaden weight at each end; to determine the magnitude of the force of torsion by the time occupied in the lateral vibrations of the bar; and to measure the extent of the change produced in its

situation by the attraction of two large masses of lead placed on opposite sides of the case containing the apparatus, so that this attraction might be compared with the weight of the balls, or, in other words, with the attraction of the earth. In this manner the mean density of the earth was found to be five and a half times as great as that of water; and although this is considerably more than had been inferred from Dr Maskelyne's observations on the attraction of Shichallain, yet the experiments agree so well with each other, that we can scarcely suppose any material error to have affected them. Mr Michell's apparatus resembled that which M. Coulomb had employed in his experiments on magnetism, but he appears to have invented it some time before the publication of M. Coulomb's Memoirs.

19. *On an improved Method of Dividing Astronomical Instruments. Phil. Trans.* 1809, p. 221. The merits of this improvement have not been very highly appreciated by those who are in the habit of executing the divisions of circular arcs. It consists in a mode of employing a microscope, with its cross wires, as a substitute for one of the points of a beam compass, while another point draws a faint line on the face of the instrument in the usual manner. The Duke de Chaulnes had before used microscopal sights for dividing circles, but his method more nearly resembled that which has been brought forward in an improved form by Captain Kater; and Mr Cavendish, by using a single microscope only, seems to have sacrificed some advantages which the other methods appear to possess; but none of them has been very fairly tried; and our artists have hitherto continued to adhere to the modes which they had previously adopted, and which it would perhaps have been difficult for them to abandon, even if they had been convinced of the advantages to be gained by some partial improvements.

Such were the diversified labours of a philosopher who possessed a clearness of comprehension, and an acuteness of reasoning, which had been the lot of very few of his predecessors since the days of Newton. Maclaurin and Waring, perhaps also Stirling and Landen, were incomparably greater mathematicians; but none of them attempted to employ their powers of investigation in the pursuit of physical discovery. Euler and Lagrange on the Continent had carried the improvements of analytical reasoning to an unparalleled extent; and they both, as well as Daniel Bernoulli and D'Alembert, applied these powers with marked success to the solution of a great variety of problems in mechanics and in astronomy. But they made no experimental discoveries of importance; and the splendid career of chemical investigation which has since been pursued with a degree of success unprecedented in history, may be said to have been first laid open to mankind by the labours of Mr Cavendish; although the further discoveries of Priestley, Scheele, and Lavoisier, soon furnished, in rapid succession, a superstructure commensurate to the extent of the foundations so happily laid. "Whatever the sciences revealed to Mr Cavendish," says Cuvier, "appeared always to exhibit something of the sublime and the marvellous; he weighed the earth; he rendered the air navigable; he deprived water of the quality of an element;" and he denied to fire the character of a substance. "The clearness of the evidence on which he established his discoveries, new and unexpected as they were, is still more astonishing than the facts themselves which he detected; and the works in which he has made them public are so many masterpieces of sagacity and of methodical reasoning, each perfect as a whole and in its parts, and leaving nothing for any other hand to correct, but rising in splendour with each successive year that passes over them, and promising to carry down his name to a posterity far more remote than his rank and connections could ever have enabled him to attain without them."

In his manners Mr Cavendish had the appearance of a quickness and sensibility almost morbid, united to a slight hesitation in his speech, which seems to have depended more on the constitution of his mind than on any deficiency of his organic powers, and to an air of timidity and reserve, which sometimes afforded a contrast, almost ludicrous, with the sentiments of profound respect which were professed by those with whom he conversed. It is not impossible that he may have been indebted to his love of severe study, not only for the decided superiority of his faculties to those of the generality of mankind, but even for his exemption from absolute eccentricity of character. His person was tall, and rather thin; his dress was singularly uniform, although sometimes a little neglected. His pursuits were seldom interrupted by indisposition; but he suffered occasionally from calculous complaints. His retired habits of life, and his disregard of popular opinion, appear to have lessened the notoriety which might otherwise have attached to his multiplied successes in science; but his merits were more generally understood on the Continent than in this country, although it was not till he had passed the age of seventy that he was made one of the eight foreign associates of the institute of France.

Mr Cavendish was not less remarkable, in the latter part of his life, for the immense accumulation of his pecuniary property, than for his intellectual and scientific treasures. His father died in 1783, being at that time eighty years old, and the senior member of the Royal Society; but he is said to have succeeded at an earlier period to a considerable inheritance left him by one of his uncles. He resided principally at Clapham Common; but his library was latterly at his house in Bedford Square; and his books were at the command of all men of letters, either personally known to him, or recommended by his friends; indeed the whole arrangement was so impartially methodical, that he never took down a book for his own use, without entering it in the loan book; and after the death of a German gentleman, who had been his librarian, he appointed a day on which he attended in person to lend any work for the accommodation of the few who thought themselves justified in applying to him for such books as they wished to consult. He was constantly present at the meetings of the Royal Society, as well as at the conversations held at the house of the president; and he dined every Thursday with the club composed of its members. He had little intercourse with general society, or even with his own family, and saw only once a year the person whom he had made his principal heir. He is said to have assisted several young men whose talents recommended them to his notice, in obtaining establishments in life; but in his later years such instances were certainly very rare. His tastes and his pleasures do not seem to have been in unison with those which are best adapted to the generality of mankind; and amidst the abundance of all the means of acquiring every earthly enjoyment, he must have wanted that sympathy which alone is capable of redoubling our delights, by the consciousness that we share them in common with a multitude of our friends, and of enhancing the beauties of all the bright prospects that surround us, when they are still more highly embellished by reflection "from looks that we love." He could have had no limitation either of comfort or of luxury to stimulate him to exertion; even his riches must have deprived him of the gratification of believing, that each new triumph in science might promote the attainment of some great object in life that he earnestly desired; a gratification generally indeed illusory, but which does not cease to beguile us till we become cal-

 lous as well to the pleasures as to the sorrows of existence. But in midst of this "painful pre-eminence," he must still have been capable of extending his sensibility over a still wider field of time and space, and of looking forward to the approbation of the wise and the good of all countries and of all ages; and he must have enjoyed the highest and purest of all intellectual pleasures, arising from the consciousness of his own excellence, and from the certainty that, sooner or later, all mankind must acknowledge his claim to their profoundest respect and highest veneration.

"It was probably either the reserve of his manners," says Cuvier, "or the modest tone of his writings, that procured him the uncommon distinction of never having his repose disturbed either by jealousy or by criticism. Like his great countryman Newton, whom he resembled in so many other respects, he died full of years and honours, beloved even by his rivals, respected by the age which he had enlightened, celebrated throughout the scientific world, and exhibiting to mankind a perfect model of what a man of science ought to be, and a splendid example of that success which is so eagerly sought, but so seldom obtained." The last words that he uttered were characteristic of his unalterable love of method and subordination; he had ordered his servant to leave him, and not to return till a certain hour, intending to pass his latest moments in the tranquillity of perfect solitude; but the servant's impatience to watch his master diligently having induced him to infringe the order, he was severely reproved for his indiscretion, and took care not to repeat the offence until the scene was finally closed. Mr Cavendish died on the 24th of February 1810, and was buried in the family vault at Derby. He left a property in the funds of about L.700,000, which he divided into six equal parts, giving two to Lord George Cavendish, the son of his first cousin, one to each of his sons, and one to the Earl of Bessborough, whose mother was also his first cousin. Some other personal property devolved to Lord George as residuary legatee; and a landed estate of L.6000 a year descended to his only brother, Mr Frederic Cavendish of Market Street, Herts, a single man, and of habits of life so peculiarly retired, that any further increase of income would have been still more useless to him than it had been to the testator.

Much as Mr Cavendish effected for the promotion of physical science throughout his life, it has not been unusual, even for his warmest admirers, to express some regret that he did not attempt to do still more after his death by the appropriation of a small share of his immense and neglected wealth to the perpetual encouragement of those objects which he had himself pursued with so much ardour. But however we might be disposed to lament such an omission, we have surely no reason to complain of his determination to follow more nearly the ordinary course of distribution of his property, among those whose relationship would have given them a legal claim to the succession if he had not concerned himself in directing it. We may observe on many other occasions that the most successful cultivators of science are not always the most strenuous promoters of it in others; as we often see the most ignorant persons, having been rendered sensible by experience of their own deficiencies, somewhat disposed to overrate the value of education, and to bestow more on the improvement of their children than men of profounder learning, who may possibly have felt the insufficiency of their own accomplishments for insuring success in the world. But even if Mr Cavendish had been inclined to devote a large share of his property to the establishment of fellowships or professorships, for the incitement of men of talents to a more complete devotion of their lives to the pursuit of science, it is very doubtful whether he could have entertained a reasonable hope of benefiting his country by such an institution; for the highest motives that stimulate men to exertion are not those which are immediately connected with their pecuniary interests. The senators and the statesmen of Great Britain are only paid in glory; and where we seek to obtain the co-operation of the best educated and the most enlightened individuals in any pursuit or profession, we must hold out as incentives the possession of high celebrity and public respect, assured that they will be incomparably more effectual than any mercenary considerations, which are generally found to determine a crowd of commercial speculators to enter into competition for the proposed rewards, and to abandon all further concern with the objects intended to be pursued as soon as their avarice is gratified. To raise the rank of science in civil life is therefore most essentially to promote its progress; and when we compare the state not only of the scientific associations, but also of the learned professions, in this country and among our neighbours, we shall feel little reason to regret the total want of pecuniary patronage that is remarkable in Great Britain with respect to every independent department of letters, while it is so amply compensated by the greater degree of credit and respectability attached to the possession of successful talent. It must not however be denied, that even in this point of view there might be some improvement in the public spirit of the country. Mr Cavendish was indeed neither fond of giving nor of receiving praise; and he was little disposed to enliven the intervals of his serious studies by the promotion of social or convivial cheerfulness; but it would at all times be very easy for an individual, possessed of high rank and ample fortune, of correct taste and elegant manners, to confer so much dignity on science and literature, by showing personal testimonies of respect to acknowledged merit, as greatly to excite the laborious student to the unremitting exertions of patient application, and to rouse the man of brilliant talent to the noblest flights of genius. (T. Y.)

Cavendish, *Margaret*, Duchess of Newcastle, famous in her day for her voluminous productions, was born about the end of the reign of James I., and was the youngest daughter of Sir Charles Lucas of Colchester. She married the Duke of Newcastle at Paris in 1645; and remained abroad till after the Restoration. On her return she wrote a vast number of plays and poems, together with the life of her husband, to the amount of about twelve folio volumes. "What gives the best idea of her unbounded passion for scribbling," says Mr Walpole, "was her seldom revising the copies of her works, lest, as she said, it should disturb her following conceptions." She died in 1673.

Cavendish, *Thomas*, of Suffolk, the second Englishman who sailed round the globe, was descended from a noble family in Devonshire. Having dissipated his fortune, he resolved to repair it at the expense of the Spaniards. He sailed from Plymouth with three small ships in 1586, passed through the Straits of Magelhaens, took many rich prizes along the coasts of Chili and Peru, and near California possessed himself of the St Anna, an Acapulco ship with a cargo of immense value. Having completed the circumnavigation of the globe, he returned home round the Cape of Good Hope, and reached Plymouth again in September 1588. Besides the wealth which he had obtained, he had the honour of contributing not a little to the progress of geographical discovery. But his hastily acquired riches did not last long; for in 1591 he had reduced himself to the necessity of undertaking another voyage, which was far from being so successful as the former. He proceeded no farther than the Straits of Magelhaens, where the weather obliged him to return. At this he became dispirited, and died of grief in the homeward voyage.

Cavendish, *Sir William*, descended of an ancient and

honourable family, was born about the year 1505, and was the second son of Thomas Cavendish of Cavendish in Suffolk, clerk of the pipe in the reign of Henry VIII. Having had a liberal education, he was taken into the family of Cardinal Wolsey, whom he served in the capacity of gentleman-usher of the chamber. In 1527 he attended his master on his embassy to France, returned with him to England, and was one of the few who continued faithful to him in his disgrace. Cavendish was with him when he died, and delayed going to court till he had seen his remains decently interred. The king was so far from disapproving of his conduct, that he immediately took him into his household, made him treasurer of his chamber and a privy-councillor, and afterwards conferred on him the order of knighthood. He was also appointed one of the commissioners for receiving the surrender of religious houses. In 1540 he was nominated one of the auditors of the court of augmentations; and soon afterwards obtained a grant of several considerable lordships in Hertfordshire. In the reign of Edward VI. his estates were much increased by royal grants in seven different counties; and he appears to have continued in high favour at court during the reign of Queen Mary. He died in 1557. Sir William was the founder of Chatsworth, and ancestor of the Dukes of Devonshire. He wrote *The Life and Death of Cardinal Wolsey*, of which a mutilated copy appeared in 1641. It was first correctly printed in Dr Woodsworth's *Ecclesiastical Biography*, 6 vols. 8vo, 1810.

Cavendish, *William*, the first Duke of Devonshire, distinguished as a statesman and patriot, was born in 1640, and spent the early part of his life abroad. In 1677, having taken his seat in parliament for Derby, he vigorously opposed the venal measures of the court; and in the following year he was one of the committee appointed to draw up articles of impeachment against the lord-treasurer Danby. In 1679 he was re-elected for Derby, and made a privy-councillor by Charles II.; but he soon withdrew from the board with his friend Lord Russell, when he found that the Popish interest prevailed. He carried up the articles of impeachment to the House of Lords against Lord Chief-justice Scroggs, for his arbitrary and illegal proceedings in the court of king's bench; and when the king declared his resolution not to sign the bill for excluding the Duke of York, afterwards James II., he moved in the House of Commons that a bill might be brought in for the association of all his majesty's Protestant subjects. He also openly denounced the king's counsellors, and voted for an address to remove them. He appeared in defence of Lord Russell at his trial, at a time when it was scarcely more criminal to be an accomplice than a witness. The same fortitude, activity, and love of his country, animated him to oppose the arbitrary proceedings of James II.; and when he saw that there was no other mode of saving the nation, he was foremost in inviting the Prince of Orange from Holland, and was the first nobleman who appeared in arms to receive him at his landing. He was created Duke of Devonshire in 1694 by William and Mary, at whose court he held several important offices. His last public service was assisting in concluding the union with Scotland, for negotiating which he had been appointed a commissioner by Queen Anne. He died in 1707, and ordered the following inscription to be put on his monument:

Willielmus dux Devon,
Bonorum Principum Fidelis Subditus,
Inimicus et Invisus Tyrannis.

CAVERY, or Cauvery, a river of Hindustan, which rises among the Coorg Hills, near the coast of Malabar, in Lat 12. 25, Long. 75. 34, and passing through the Mysore near Seringapatam, Coimbetoor, and the Carnatic, below the Ghauts, falls into the Bay of Bengal by several mouths, after a winding course of nearly 500 miles. Opposite to Trichinopoly, in the Carnatic, the Cavery is divided just below the island of Seringham into two branches. The northern branch is named the Coleroon; the southern continues to bear the name of Cauvery. Extensive systems of canal irrigation, in connection with both branches of the river, have been constructed of late years by the British government; the effects of which have been to render the district of Tanjore one of the most fertile provinces of the presidency of Madras.

CAVIARE, a kind of food consisting of the salted roes of large fish, the best being that of the sturgeon. It is usually packed in kegs; and an inferior kind is formed into small dry cakes about an inch thick and three or four inches broad. Caviare is chiefly made in Russia, especially at Astrachan, where it is called *ikra*. It is greatly esteemed by that nation, and is also consumed in considerable quantities in Italy and France.

CAVITE, a fortified seaport-town, capital of a province of the same name in the island of Luzon, Philippines, on a tongue of land in the bay, and nine miles south of the city of Manilla. It is the head naval depôt of the Spanish possessions in the East, and has an arsenal, hospital, and several churches and convents. It was formerly of considerable importance. Pop. 5000.

CAWNPORE, a British district of Hindustan, named from its principal town, and situate within the jurisdiction of the lieutenant-governor of the north-western provinces of Bengal. It lies within the tract of country stretching from the Ganges to the Jumna, the latter river constituting its south-western boundary, and the former its north-eastern frontier. It extends from Lat. 25. 55. to 27., and from Long. 79. 34. to 80. 37.; is 75 miles in length from north to south, and 65 in breadth. The population has been returned at 993,031. The Ganges and the Jumna are both navigable throughout their entire course along this district; and the means of water-carriage and irrigation in this part of the north-western provinces will shortly be vastly increased by the prolongation of the Ganges canal, the line of which has been laid down on the highest tract of the district with a view to its termination at the city of Cawnpore, where the canal will rejoin the parent stream. The lands of Cawnpore are fertile and highly cultivated, few spots being left to nature except those cut up by ravines. The principal crops are wheat, barley, maize, pulse, oil-seeds, sugar-cane, and potatoes. The opium poppy (recently introduced) thrives well, as does also tobacco. Cotton is an important crop, and indigo is considered indigenous. The esculent vegetables of Europe are produced in great abundance; as are also grapes, peaches, mangoes, shaddocks, plantains, limes, and oranges. The district was ceded to the British government by the nawaub of Oude in 1801, in commutation of the annual subsidy payable by the nawaub for the maintenance of a British military force. The city of Cawnpore is situate on the right bank of the Ganges, stated to be here 500 yards wide at the season of low water. It covers an area of 690 acres, and contains about 11,000 houses, with a population of 59,000 inhabitants, exclusive of the military and the population of the cantonments. It is known as one of the principal military stations of the British in the Doab. The buildings which have been erected here for the accommodation of the troops are barracks for four hundred artillery, two regiments of European and three of native cavalry, and seven thousand native infantry, with a general hospital for the reception of the sick. The officers of every description provide their own lodgings, which consist of elegant bungalows built without any regularity, and which extend about six miles along the Ganges. Cawnpore is subject to great heats. The hot winds blow here with great violence during the months of April, May, and June; not a drop of rain then falls; and from the parched ground clouds of dust arise so thick as to obscure the sun, and to envelope the station in darkness. Cawnpore is nevertheless

esteemed a healthy station. Bishop Heber remarks that "there are many handsome mosques, and the view of the town from the course gives quite the idea of a city:" and adds, "On the whole, it is in many respects one of the most considerable towns which I have seen in Northern India; but, being of merely modern origin, it has no fine ancient buildings to show. The European architecture is confined to works of absolute necessity only, and marked by the greatest simplicity; and few places of its size can be named where there is so absolutely nothing to see." Distant S.W. from Lucknow, 53 miles; N.W. from Calcutta, 628 miles. Lat. 26. 29., Long. 80. 25.

CAXAMARCA, a city of Peru, capital of a province of the same name, department of Truxillo. It is pleasantly situate in a valley of the same name, on the eastern side of the Andes, about 9400 feet above the sea, and 80 miles N.N.E. of Truxillo. It has a considerable trade, and extensive manufactures of iron and silver wares. Pop. about 7000, chiefly Indians and Mestizoes. It has a number of fine churches and a gymnasium; and in the vicinity are the baths of the Incas. Among its public buildings is the ancient palace of the Incas, where Atahualpa, the last Inca of Peru, was basely murdered by the Spaniards.

CAXTON, William (1410–1492), the earliest English printer. See Printing.

CAYENNE, an island of South America. See Guiana,

Cayenne, a seaport-town and capital of French Guiana, on the N.W. extremity of the island of that name, in Lat. 4. 56. N., Long. 52. 15. W. It contains about 500 houses, mostly of wood, and is divided into the old and new towns, the latter clean and well built. It is the seat of a court of assize; and has a handsome church, Jesuit college, government house, and several large warehouses. The harbour is shallow, has two quays, and is protected by a fort and several batteries. Pop. about 6000.

Cayenne *Pepper* is prepared from several varieties of capsicum, a genus of solanaceous plants which produce a fleshy-coloured fruit. This fruit contains an extremely pungent principle, that exists in greatest activity in the seed. The capsicum from which the Cayenne is procured is a native of the East Indies and America. The principal Indian species is *C. frutescens*, and the American *C. annuum*. The capsicum enters largely into the seasoning of food and the preparation of pickles; and is also used in medicine, both internally and externally. The pods may be preserved in vinegar, or in a dry state in salt. The strongest variety of Cayenne pepper comes from the West Indies, and is prepared from the *Capsicum baccatum* (bird pepper).

CAYLUS, Anne-Claude, Philippe de Tubieres, de Grimoard, de Pestels, de Lévi, Comte de, Marquis d'Esternay, Baron de Bransac, was born at Paris in October 1692. He was the eldest of the two sons of John Count de Caylus lieutenant-general of the armies of the king of France, and of the Marchioness de Villette. The countess was the niece of Madame de Maintenon, and the author of a book entitled *Souvenirs de Madame de Caylus*, of which Voltaire published an elegant edition. Count de Caylus was only twelve years of age when his father died. He entered the corps of the *Mousquetaires;* and in his first campaign, in 1709, distinguished himself so much, that Louis XIV. rewarded him with an ensigncy in the *gens-d'armerie*. In 1711 he commanded a regiment of dragoons which was called by his own name, and signalized himself at the head of it in Catalonia. In 1713 he was present at the siege of Fribourg, where he was exposed to imminent danger in the bloody attack of the covered way. After the peace of Rastadt he travelled in Italy; and returned to Paris with so strong a passion for antiquities, that he resolved to devote himself entirely to that pursuit.

He had no sooner left the service of Louis than he set out for the Levant; and passed from Smyrna to Constantinople. He next visited Greece and the East, exposing himself to fatigue, contagion, and danger, in order to gratify his thirst for knowledge. He visited the ruins of Ephesus, and the other interesting cities of Ionia, under the escort of robbers belonging to a troop or band called Caracayali; returned to Byzantium by the Dardanelles; and lastly repaired to Adrianople, where the sultan, Mustapha II., then resided. In February 1717 he returned home at the urgent solicitation of his mother. From that time he only left France to make two excursions to London. The Academy of Painting and Sculpture admitted him as an honorary member in the year 1731; and the Count in return spared neither labour, credit, nor fortune, to instruct and assist the artists. He wrote the lives of the most celebrated painters and engravers who had done honour to the academy; and, in order to extend the limits of the art, he collected, in three different works, new subjects for painting which he had met with in the works of the ancients.

Regretting the decay which almost immediately followed the disentombment of ancient paintings, he caused a large collection of coloured drawings, taken by Pietro S. Bartoli from antique pictures, to be engraved at his own expense, and presented them to the cabinet of the king of France. Of the engravings only thirty copies were published. The inimitable purity and precision of the originals renders it a collection entirely unique.

Count Caylus was himself an admirable engraver, and produced numerous works, finished in a slight masterly style. They are almost all executed with the *point*, and scarcely show traces of the *graving-tool*. Upwards of 200 of his plates "from the drawings of the great masters" are preserved in the Imperial Library of France: and his "Heads after Rubens and Vandyck" were preserved in the cabinet of Crozat. He engraved also a set of "Antique Gems;" and his Collection of "Heads after Lionardo da Vinci" was published in 1730.

Count Caylus was at the same time engaged in an enterprise alike illustrative of the greatness of Rome and the history of France. This consisted in finishing the edition of engravings taken from Mignard's drawings of Roman antiquities in France, which Colbert had begun. At his death he left this design unfinished, and bequeathed it in his last illness to M. Mariette.

In 1742 Count Caylus was admitted as an honorary member of the Academy of Belles-Lettres; and from that time the study of literature became his ruling passion. To it he consecrated his time and his fortune; he even renounced his pleasures to give himself wholly up to the object of making some discovery in the field of antiquity. Amidst the fruits of his research nothing afforded him so much gratification as his discovery of encaustic painting. A description of Pliny, too concise to give a clear view of the matter to an ordinary reader, suggested the idea of this art to M. de Caylus. He availed himself of the friendship and skill of M. Magault, a physician in Paris, and an excellent chemist; and by repeated experiments discovered the secret of incorporating wax with various tints and colours, and of rendering it manageable with the pencil. Pliny has made mention of two kinds of encaustic painting practised by the ancients, one of which was executed with wax on various substances, and the other upon ivory with hot punches of iron. It was the former kind, however, that Count Caylus had the merit of reviving; and M. Muntz afterwards made many experiments in order to carry it to perfection.

In the hands of Count Caylus literature and the arts lent each other mutual aid. But it would be endless to give an account of all his works. He published above forty dissertations in the Memoirs of the Academy of Belles-Lettres; and founded a prize of five hundred livres, the object of which was to explain, by means of authors and monuments,

the usages of ancient nations. To render as generally accessible as he could the treasures which he had collected, he caused them to be engraved, and gave a learned description of them in a work which he embellished with eight hundred copperplates.

The strength of his constitution seemed to give him hopes of a long life; but a disease which settled in one of his legs entirely destroyed his health, and he expired on the 5th of September 1765. His character is thus drawn by a French biographer:—" A severe probity, a rooted aversion to flattery, great indifference about honours, a singular simplicity, perhaps sometimes a little dogmatism in his opinions, formed the basis of his character. In him young artists found both a guide and a friend; and with a discernment and a delicacy still more rare than generosity, he anticipated the wants of those whose progress would have been otherwise retarded by the narrowness of their means. Naturally beneficent, he sometimes amused himself when he met a pauper whose appearance indicated probity, by giving him a louis to get changed, and then concealing himself where he could enjoy the poor creature's embarrassment when the person from whom he received the gold was not to be found. Caylus, indeed, never knew any other luxury than that of liberality. His dress, in particular, was so plain that, having one day stopped before a shop on which a sign-painter was painting a figure of St Francis, the latter, taking him for one of his comrades, asked his opinion respecting the work, which Caylus instantly gave him, and which delighted the painter so much, that he put the pallet and pencil into the hand of his new acquaintance, and begged him to retouch the picture. Caylus mounted the ladder, and having succeeded to the entire satisfaction of the painter, the latter wished to take him to a neighbouring tavern, when the carriage of the Count arrived, and his footman opened the door for his master. The painter of saints and signs was stupefied with astonishment; but Caylus, taking him by the hand, said, *Au revoir, camarade, ce sera pour la première fois que nous nous rencontrerons.*"

The numerous literary works of Count Caylus may be divided into three classes; humorous pieces and romances; productions relative to the fine arts; and those which treat exclusively of antiquities. I. The first class consists of, 1. *Les Eccosseuses, ou les Œufs de Pâques*, Troyes, 1739 et 1745, 12mo; 2. *Histoire de Guillaume, Cocher*, 12mo; 3. *Féeries Nouvelles*, Paris, 1742, 2 vols. 12mo; 4. *Soirées du Bois de Boulogne*, Paris, 1742, 12mo; 5 *Etrennes de la St Jean*, in conjunction with Moncrieff, Crebillon the younger, Duclos, La Chaussé, Voisenon, and others; 6. *Contes Orientaux*, 1743, 12mo; 7. *Histoire de Mlle. Cronel, dite Frétillon (Mlle. Clairon)*, Paris, 1743, 12mo; 8. *Histoires Nouvelles et Mémoires ramassés*, Paris, 1743; 9 *Quelques Aventures des Bals de Bois*, 1745, 12mo; 10. *Cinq Contes des Fées*, 1745, 12mo; 11. *Recueil de ces Messieurs*, 1745, 12mo; 12. *Les Manteaux*, Paris, 1746, 12mo; 13. *Les Fêtes roulantes et les Regrets des petites rues*, 1747, 12mo; 14. *Mémoires de l'Académie des Colporteurs*, 1748, 8vo; 15. *Le Calsandre fidèle*, translated from the Italian of Marini, Paris, 1740, 3 vols. 12mo; 16. *Histoire du Vaillant Chevalier Tyran-le-Blanc*, translated from the Spanish, London, 1775, 3 vols. 12mo; with some other pieces which are attributed to him. II. His works relating to the fine arts are, 1. *Nouveaux Sujets de Peintre et de Sculpture*, Paris, 1755, 12mo; 2. *Tableaux tirés de l'Iliade, de l'Odyssée et de l'Enéide, avec des Observations générales sur le Costume*, Paris, 1757, 8vo; 3. *Histoire d'Hercule le Thébain*, Paris, 1758, 8vo; 4. *Les Vies de Mignard et de Lemoyne* in the *Recueil des premiers Peintres du Roi*, Paris, 1752, 8vo; 5. *Mémoire sur la Peinture à l'Encaustique*, 1755, 8vo; 6. *Description d'un tableau représentant la sacrifice d'Iphigénie*, 1757, 12mo; 7. *Vie d'Edme Bouchardon*, Paris, 1762, 12mo. III. His works relative to antiquities are, 1 *Recueil d'Antiquités Egyptiennes, Etrusques, Grecques, Romaines, et Gauloises*, Paris, 1752, and the years following, 7 vols. 4to; 2. *Numismata Aurea Imperatorum Romanorum*, without date, 4to, very rare; *Recueil de Medailles du Cabinet du Roi*, no date, 4to, also very rare; 4. *Dissertation sur le Papyrus*, Paris, 1758, 4to, in the *Mémoires de l'Académie des Inscriptions*; 5. *Recueil de Peintures antiques*, Paris, 1757, fol.

CAYSTER, or CAYSTRUS, in *Ancient Geography*, a river of Lydia and Ionia, which rises in the Montes Cilbiani, and falls into the sea a little to the north of Ephesus. At the foot of Mount Gallesus it is crossed by an ordinary bridge of three arches. It is sometimes called by the Turks Little Meendras, after the river Meander, which it resembles in its windings. At its mouth was the Asius Campus, noted for the flocks of wild fowl by which it was frequented. The Cayster was a favourite haunt of the wild swan.

CAZALLA DE LA SIERRA, a town of Spain, province of Seville, on the Sierra Morena, in the neighbourhood of extensive marble quarries, and mines of silver, iron, sulphur, and copper, from which, as well as from agriculture, it derives its trade. In the suburbs are remains of Roman and Moorish antiquities. Its manufactures are purely domestic. Pop. 6552.

CAZIQUE, or CACIQUE, a title given by the Spaniards to the native princes and chiefs of the several countries of America, when they first visited that country.

CAZORLA, a town on the Vega, Jaen, Spain. It contains about 964 houses, generally well built, 2 old castles, one of them Arabic, 2 schools, several hospitals, a spacious theatre, a very ancient church, and several convents. Agriculture is the prevailing occupation. Pop. 7383. Cazorla was an important military station under the Romans and Moors; and has suffered considerably during the vicissitudes of the civil wars in Spain.

CEBES, of Thebes, a Socratic philosopher, author of a work entitled Πίναξ, (*Tabula*), or *Dialogues on the Birth, Life, and Death of Mankind*. He was the disciple and intimate friend of Socrates. The above work is mentioned by Lucian, Diogenes Laertius, Tertullian, and Suidas; but of Cebes himself we have no account, save an accidental notice by Plato, and another by Xenophon. The former says in his *Phædo* that Cebes was a sagacious investigator of truth, and never assented without the most convincing reasons; the latter, in his *Memorabilia*, ranks him among the few intimates of Socrates who excelled the rest in the innocence of their lives. The *Tabula* of Cebes is usually printed with the *Manuale* of Epictetus. It has been translated into all the languages of Europe, and into Arabic.

CECIL, WILLIAM, Lord Burleigh, treasurer of England in the reign of Queen Elizabeth, was the son of Richard Cecil, Esq., master of the robes to King Henry VIII. He received the rudiments of his education in the grammar-school at Grantham; and from this seminary he was removed, first to Stamford, and afterwards about the year 1535 to St John's College, Cambridge. Here he began his studies with great enthusiasm. At the age of sixteen he read a sophistry lecture, and at nineteen a voluntary lecture in Greek. In 1541 he went to London, and became a member of the society of Gray's Inn, with an intention of studying the law; but he had not been long in this situation before an accident introduced him to King Henry, and gave a new bias to his pursuits. O'Neil, a famous Irish chief, having brought to court with him two Irish chaplains, adherents of the Romish faith, Mr Cecil, happening to meet these ecclesiastics when on a visit to his father, had a warm dispute with them in Latin, in which he displayed uncommon abilities. The king, being informed of the circumstance, summoned Cecil into his presence, and granted him the reversion of the *custos brevium* at the court of common pleas. About this time he married the sister of Sir John Cheke, by whom he was recommended to the Earl of Hertford, afterwards Duke of Somerset and protector.

Soon after King Edward's accession, Mr Cecil came into the possession of the office of *custos brevium*, worth about L.240 a year; and married, as his second wife, the daughter of Sir Anthony Cook, director of the king's studies. In 1547 he was appointed by the protector master of requests; and soon afterwards accompanying the expedition against the Scots was present at the battle of Musselburgh, where his life was miraculously preserved by a friend, who, on

Cecil.

pushing him out of the line of a cannon-shot, had his arm shattered to pieces. The story is told in his life by a domestic. In the year 1548 Mr Cecil was made secretary of state; but in the following year when the Duke of Northumberland's faction prevailed, he shared in the disgrace of the protector Somerset, and was sent prisoner to the Tower. After three months' confinement he was released, restored to his office in 1551, and soon afterwards knighted and sworn a member of the privy-council. In 1553 he was made chancellor of the order of the Garter, with an annual fee of a hundred merks.

On the death of Edward VI. Sir William Cecil refused to take any part in Northumberland's attempt in favour of the unfortunate Lady Jane Grey; and when Queen Mary succeeded to the throne, he was graciously received at court; but not choosing to change his religion, was dismissed from all his employments. During this reign he was twice elected knight of the shire for the county of Lincoln, and often spoke in the House of Commons with great freedom and firmness, in opposition to the ministry. So great was his tact and prudence, that, though a Protestant and a patriot, he was suffered to live unmolested during the whole of that reign.

Queen Elizabeth's accession, in the year 1558, immediately restored him to his former rank and influence. During the reign of her sister he had constantly corresponded with the princess Elizabeth; upon the very day of her accession, he presented her with a paper containing twelve articles necessary for her immediate despatch; and in a few days after he was sworn a privy-councillor and made secretary of state. His first advice to the queen was to call a parliament; and the first business he proposed after it had assembled was the establishment of a national church. A plan of reformation was accordingly drawn up under his immediate inspection, and the legal establishment of the Church of England was the consequence. Sir William Cecil's next important concern was to restore the value of the coin, which had been considerably debased in the preceding reigns. In 1561 he was appointed master of the wards, and, in 1571, created Baron of Burleigh as a reward for his services, particularly in having lately stifled a formidable rebellion in the north. The following year he was honoured with the garter, and raised to the office of lord high treasurer of England. From this period we find him the principal agent in every material transaction during the glorious reign of Queen Elizabeth. Notwithstanding the temporary influence of other favourites, Lord Burleigh was her prime minister, and the person in whom she chiefly confided in matters of real importance. Having filled the highest and most important offices of the government for forty years, and guided the helm of the state during the most glorious period of English history, he died on the 4th of August 1598, in the seventy-eighth year of his age. His body was removed to Stamford, and there deposited in the family vault, where a magnificent tomb was erected to his memory.

He wrote, 1. *La Complainte de l'Ame pêcheresse*, or the Complaint of a sinful Soul, in French verse; 2 Materials for Patten's *Diarium Exped. Scoticæ*, London, 1541, 12mo; 3. Slanders and Lies, maliciously, grossly, and impudently vomited out in certain traiterous books and pamphlets against two counsellors, Sir Francis Bacon and Sir William Cecil; 4. A Speech in Parliament, 1562, Strype's Mem., vol. iv., p. 107; 5. Precepts or Directions for the well ordering of a Man's Life, 1637, Harl. Cat., vol. ii., p. 755; 6. Meditations on the Death of his Lady, Ballard's Mem., p. 184; 7. Meditations on the state of England during the reign of Queen Elizabeth, manuscript; 8. The execution of justice in England for the maintenance of public and Christian peace, &c, Lond, 1581, 1583, Somer's Tracts, 4th Collect, vol. i., p. 5; 9. Advice to Queen Elizabeth in Matters of Religion and State, *ib.*, p. 101, 106; 10. A great number of Letters; 11. Several Pedigrees, some of which are preserved in the Archbishop of Canterbury's library at Lambeth.

CECIL, Robert (1550–1612), son of the preceding, was delicate in constitution, and deformed in person, but early distinguished himself in parliament, to which he was sent as member for Westminster In 1588, he went on board the fleet which was sent by Elizabeth against the Spanish Armada, and on his return was rapidly promoted to places of honour and trust at court. Having been knighted by the queen, he was sent as an attaché to the English embassy in France, and afterwards sworn a member of the privy-council. He held the office of second secretary of state till the death of Sir Francis Walsingham, when he was appointed principal secretary—an office which he held till his death. During the reign of Elizabeth, he was intrusted with the conduct of numerous delicate negotiations abroad, and on the death of his father in 1598, was appointed prime minister. Having previously kept up a secret correspondence with James I., he was not only confirmed in his office, but raised to additional dignities on the accession of that monarch. It is well remarked by Lord Hailes, that this consummate politician "was no less solicitous to maintain his own power than to settle the succession to his aged benefactress Queen Elizabeth." (*Pref. to Cecil's Correspond.*) He was created successively Baron of Essenden, Viscount Cranbourne, and Earl of Salisbury, and notwithstanding the efforts of the Spanish court through their ambassadors to bring him into disgrace on account of his attachment to the interests of the United Provinces, he continued to rise in popular estimation. On the death of Sir Thomas Sackville, he was appointed lord high treasurer, in which capacity he effected considerable reforms in the exchequer. He died at Marlborough in 1612, and was buried at Hatfield. He wrote *A Treatise concerning the State and Dignity of a Secretary of State, with the care and peril thereof; A Treatise against the Papists; and Notes on Sir John Dee's Discourse about the Reformation of the Calendar.*

Cecilia.

CECILIA, St, the patron saint of music, has been honoured as a martyr ever since the fifth century. Her story, as delivered by the Notaries of the Roman Catholic church, and thence transcribed into the Golden Legend and similar books, says that she was a Roman lady, born of noble parents about the year 295; that, notwithstanding she had been converted to Christianity, her parents married her to a young Pagan nobleman named Valerianus, who on the wedding night was given to understand by his spouse that she was nightly visited by an angel, and that he must forbear to approach her, otherwise the angel would destroy him. Valerianus, troubled at these words, desired that he might see his rival the angel; but he was told that was impossible, unless he would consent to be baptized and become a Christian. To this he consented; after which, returning to his wife, he found her in her closet at prayer, and by her side, in the shape of a beautiful young man, an angel clothed with brightness. After some conversation with the angel, Valerianus told him that he had a brother named Tiburtius, whom he greatly desired to see a partaker of the grace which he himself had received. The angel answered that his desire was granted, and that they should be both crowned with martyrdom in a short time. Upon this the angel vanished, and was not long in showing that he had kept his word; for Tiburtius was converted, and both he and his brother Valerianus were beheaded. Cecilia was offered her life upon condition that she would sacrifice to the deities of the Romans, but she refused; upon which she was thrown into a caldron of boiling water and scalded to death. Others say, that she was stifled in a dry bath, or an inclosure from which the air had been excluded, heated by a slow fire underneath; a kind of death which was sometimes inflicted by the Romans on women of rank who were criminals. Upon the spot where her house stood is a church, said to have been built by Pope Urban I., who administered baptism to her husband and his brother. This church is that of St Cecilia in Trastevere; and within it is a curious painting of the saint, and a stately monument surmounted by a cum-

bent statue with the face downwards. There is a tradition that St Cecilia excelled in music, and that the angel was drawn from the celestial regions by the charms of her melody; hence she came to be regarded as the patroness of music and musicians. The legend of St Cecilia has furnished the subject of several exquisite works of art. Raphael has painted the saint in the attitude of singing with a regal in her hand; and Domenichino and Mignard in that of singing and playing on the harp.

CECROPS, the founder and first king of Athens, supposed to have been contemporary with Moses. He was the first who established civil government, religious rites, and marriage among the Greeks. He reigned fifty years. See ATHENS, and ATTICA.

CEDAR. See PINUS, PLANTING, SYRIA, TIMBER.

CEDRENUS, GEORGIUS, a Greek monk, who lived in the eleventh century, and wrote Annals, or an abridged History, from the beginning of the world to the reign of Isaac Comnenus, emperor of Constantinople, who succeeded Michael IV. in 1057. This work is no more than a compilation from several historians. There is an edition of it printed at Paris, 2 vols. fol., 1647, with the Latin version of Xylander, and the notes of Father Goar, a Dominican. A more recent edition has been published by Immanuel Bekker, 2 vols. 8vo, Bonn, 1838–9.

CEFALU, a fortified seaport-town on the north coast of Sicily, intendancy and 40 miles E.S.E. of Palermo. It is tolerably well built, but its port is small, and its trade inconsiderable. On the summit of a lofty conical hill above the town are ruins of a Saracenic castle. Pop. about 9000.

CEHEGIN, a town of Murcia, Spain, 3 miles east from Caravaca. Its houses, 1616 in number, are generally handsome, being built chiefly of marble from the neighbouring quarries, and its civil, religious, and educational establishments are in a comparatively prosperous condition. It possesses a considerable trade in agricultural produce, especially wine, hemp, and oil; and also several manufactories of paper and coarse linen. Pop. 10,354.

CEILING, the top or roof of a room. See ARCHITECTURE. In ship-building it denotes the lining or inside planks of a ship.

CEIMELIA, (from κειμαι, to be laid up) in *Antiquity*, treasures or other things stored up as valuable in a *ceimelarchium*, *i. e.* a storehouse or repository. Thus, sacred vestments, plate, and the like, are the ceimelia of a church. Medals, antique stones, manuscripts, &c., are the ceimelia of men of letters.

CEIMELIOPHYLAX (from κειμήλιον, a treasurer, and φυλάσσω, to guard), or ceimeliarcha, an officer in the ancient churches or monasteries, answering to what was otherwise denominated *chartophylax* and *custos archivorum*.

CELANO, LAKE, see FUCINUS LACUS.

CELARENT, among logicians, a mode of syllogism, in which the major and the conclusion are universal negative propositions, and the minor a universal affirmative.

E. gr. cE None whose understanding is limited can be omniscient.
lA Every man's understanding is limited.
rEnt Therefore no man is omniscient.

CELASTRUS, the staff-tree, a genus belonging to the natural order Celastraceæ. See BOTANY, p. 189. In Senegal the negroes use the powder of the root of this plant as a specific against gonorrhœa.

CELATURE, the art of engraving and embossing. Under the term *cælatura*, the ancients included every kind of ornamental work in metal, with the exception of statues.

CELBRIDGE, a pleasantly situated and well built town of Ireland, county of Kildare, on the Liffey, 11 miles west of Dublin. It has a church, chapel, savings-bank, hospital, large woollen factory, a handsome stone bridge over the river; and in 1851, 1674 inhabitants.

CELEBES, an important group of islands in the Indian Archipelago, the principal of which extends from N. Lat. 1. 45. to S. Lat. 5. 45.; and from E. Long. 113. 10. to 116. 45. Its length is estimated at 576, its average breadth at 75 miles, and its area is by various authorities computed at 75,000 square miles. The Portuguese, by whom the island was invaded in the sixteenth century, appear to have been the first Europeans by whom any part of it was occupied. English and Danish settlements, which were not long maintained, were afterwards formed on various parts of the coast. The Dutch ultimately acquired permanent possession of all the most important districts, the native princes having given their assent to treaties by which they acknowledged the sovereignty of that power, and placed themselves under its protection. The island of Celebes and its surrounding groups now constitute one of the most valuable colonial possessions of Holland. Celebes is described as very irregular in its conformation, the most considerable portion of the island consisting of four great peninsulas, the form of which is determined by three arms of the sea, extending from east to west far into the land, and its coast is penetrated in all directions by numerous small gulfs and bays. The whole of it, but particularly the interior and northern parts, are very mountainous, the highest elevations being Lampo-Betang, 7000 feet, and Mount Klabat, 6000 feet high. There are also several other mountains and volcanoes, both active and extinct, ranging from 5000 to 3000 feet in height. The northern districts of Mongondo and Menado, in some parts of which there are immense quantities of sulphur, have been frequently exposed to severe shocks of earthquakes. In its physical constitution, the island consists for the most part of ignigenous rocks, particularly basalt in a state of decomposition, covered with a vegetable soil of various degrees of depth. Between the elevated regions of the interior and the coasts are extensive plains of great fertility, beautiful valleys covered with a rich intertropical vegetation, and picturesque lakes surrounded by richly wooded banks. In the northern parts of the island there are several mines of copper, tin, iron, and gold. Considerable quantities of the more precious metal, which is found in the form of dust and spangles, are unfortunately lost in consequence of the imperfect system of gold washing adopted by the natives. The highly tempered weapons of the natives are manufactured by themselves from steel and the metal to which they give the name of *pamor*. The vegetable productions of the island, which are both numerous and valuable, consist of nutmegs, pepper, cloves, ginger, sago, tapioca, cocoa, coffee, the sugar-cane, rice, maize, and tobacco. The ebony tree, the palm, the sandal, the banana, the silk cotton tree, the indigo plant, the samuk, the calambang, the waranguin, the bamboo, the lingoa, and tanjoung, also flourish in various parts of Celebes. No formidable beast of prey is known to exist in any part of the island, the only peculiar animals being some species of the monkey tribe, such as the *papio niger*, and the *papio nigrescens*, several kinds of bats, the *sus babirussa*, the antelope *depressicornis;* and a small but spirited race of horses, great numbers of which are sent to Batavia, Madras, and Calcutta. The rivers, of which the principal are the Gea, the Sadang, the Maros, and the Boli, are frequented by crocodiles, lizards, and serpents of various kinds. The transparent sea of those regions, which sometimes assumes an appearance of milky whiteness, supposed to be caused by the presence of an immense number of microscopical mollusca on the surface, contains a great number of those crustacea and mollusca which are so much admired and sought after by the lovers of curiosities. When the waters are calm, fields of zoophytes may be distinctly perceived at a considerable depth extending their branches on all sides in ever-changing varieties of form and colour

The peninsulas extending to the north, the south, and the east, are the only parts of the island which have been re-

garded by the Dutch as commercially important, or which have ever been explored by any Europeon. Each of these peninsulas includes a great number of petty states, of which Macassar (native capital Goa, upon a river of the same name), Boni, Wadjo, and Mandhar are among the principal, all governed by native kings, princes, sultans, and rajahs, who are either subject to the Dutch government or under its influence and protection. The town of Macassar, which is situated at the south-western extremity of the southern peninsula stretching out into the sea of Java, is the chief European settlement. The governor of the island, who is assisted in the administration of its affairs by five residents located in different districts, resides here. Macassar is admirably situated for commercial purposes, being in the direct line of the navigation connected with the straits of Malacca, the principal ports of Java, the Moluccas, the southward route to Australia, and the ports which China has opened to the ships of all nations. The northern peninsula, known as the residence of Menado, comprehends all that portion of the island situated between the bay of Palos and Cape Taliabo. The other two peninsulas (in one of which is the bay of Vosmaer, the superior advantages of which for European commercial settlements have been so strongly represented by one of the late Dutch residents, whose name has been bestowed upon it) have hitherto been regarded by the government as only of secondary importance. Of the numerous groups of smaller islands by which Celebes is surrounded, the principal are Salajer, Sangir, Talant, Boeton, Moena, Kambeina, and Wangi Wangi. The population of Celebes, which consists of the aboriginal Alfoeres, Malays, Chinese, and Dutch, is estimated to amount to 1,104,000; although by some the computation has been carried as high as 3,000,000, which is considered, however, by the most intelligent judges as far above the actual number. According to the approximative census of 1838, the population immediately subject to the government of the Netherlands amounted only to 410,000. The Malays, who in religion are Mohammedans, are said to have come originally from Sumatra, to have conquered the districts on the coast, and, with the exception of a few whom they compelled to adopt their manners, customs, and religion, to have driven all the native inhabitants into the interior. The Alfoeres, Minahasses of the north, while worshipping several secondary deities and holding the doctrine of metempsychosis, profess to believe in one supreme being whom they name Epong. The Malays and Alfoeres, living in the neighbourhood of the European settlements, are described as active, intrepid, and brave; but when their passions are roused, and their jealousy or suspicion excited, as haughty, vindictive, and cruel. In some of the more remote districts, particularly in the south-eastern peninsula, the natives are extremely uncultivated and savage. The barbarous custom of cutting off heads in order to adorn their persons, weapons, houses, and tombs, with portions of the skull and the hair of their victims, still continues to be practised. Piracy is carried on to a great extent all along the coast and in the neighbouring islands; and it is almost hopeless for the industrious agricultural and fishing communities who are settled in the more remote and unprotected districts to carry on their labours with any probability of ultimate benefit. Many of the Malays and Alfoeres are actively engaged in commerce, the articles which they convey from the island in their pirogues being coffee, rice, bees' wax, cocoanut oil, palm sugar, Macassar mats, tortoise-shell, and *goemoeti*, a very strong kind of cordage produced from the fibres of one of the species of the palm-tree growing in Celebes. The principal imports which they bring back in return are cotton and silk manufactures, arak, iron, steel, copper utensils, and the various productions of China. Celebes altogether presents one of the most promising fields for commercial enterprise and manufacturing industry. Being free from that pestilential miasma by which many other tropical regions are rendered so unhealthy for Europeans, possessing a salubrious climate and a fertile soil, it may reasonably be anticipated that when the island has been more thoroughly explored, civilization more widely spread, the barbarous and superstitious customs of its inhabitants extirpated, and its commercial advantages more fully appreciated, it will ultimately become, like Java, one of the most valuable dependencies of the crown of Holland.

CELERES, in Roman antiquity, a regiment of body-guards established by Romulus, composed of three hundred young men of the most illustrious families, and approved by the suffrages of the curiæ of the people, each of which furnished ten. The name was given them because of their promptness to obey the king, whom they attended both in peace and in war. In war they formed the vanguard in the engagement; in retreats the rearguard. Though the *celeres* were a body of horse, yet they usually dismounted and fought on foot. Their commander was called *Tribunus Celerum*. They were divided into three centuries, each commanded by a captain called centurio; and their tribune occupied the second place in the state. Plutarch says that Numa broke the *celeres*. If this be true, they were soon re-established; for we find them under most of the succeeding kings. Brutus, who expelled the Tarquins, was tribune of this *corps d'élite*. See EQUITES.

CELERITY, the swiftness of any body in motion. It is also defined as an affection of motion by which a movable body runs through a given space in a given time.

CELERY (σέλινον), a variety of *Apium graveolens*. See HORTICULTURE.

CELESTINE, the name of five popes. See POPE.

CELESTINS, a religious order, so called from their founder Peter de Mouron, afterwards Pope Celestine V. He was born of humble parents at Ifernia in the kingdom of Naples in 1215; and retired while very young to a solitary mountain, in order to dedicate himself to prayer and mortification. The fame of his piety soon attracted followers; and with these in 1254 he formed a kind of community, which ten years later was approved by Pope Urban IV. and erected into a distinct order, called the *Hermits of St Damien*. Peter de Mouron governed this order till 1286, when his love of solitude induced him to quit the charge. In July 1294 he was raised to the pontificate by the name of Celestine V. By a bull he approved of the constitution of the Celestins, and confirmed all their monasteries to the number of twenty. After governing the church but five months and a few days, he found that he was unequal to the burden, and renounced the pontificate in a consistory held at Naples.

After his death, which happened in 1296, the Celestins made great progress, not only in Italy, but likewise in France, whither in 1300 the then general, Peter of Tivoli, sent twelve religious persons at the desire of Philip the Fair, who gave them two monasteries; one in the forest of Orleans, the other in the forest of Compiègne. This order also passed into several provinces of Germany. They possessed about ninety-six convents in Italy, and had twenty-three in France at the time of their suppression in 1778.

The Celestins rise two hours after midnight to say matins; eat no flesh except when sick; and observe frequent fasts. Their habit consists of a white gown, a capuche, and a black scapulary. In the choir, and when they leave the monastery, they wear a black cowl with the capuche.

CELEUSMA, or CELEUMA (from κελεύω), in *Antiquity*, the command or call given by the chief oarsman to the rowers. This officer was called *celeustes*; and by the Romans *portisculus*, *pausarius*, or simply *hortator*. His duties are well described by Silius Italicus—

> Mediæ stat margine puppis,
> Qui voce alternos nautarum temperet ictus,
> Et remis dictet sonitum, pariterque relatis
> Ad sonitum plaudat resonantia cærula tonsis.

CELIBACY (*cœlibatus*, or *cælibatus*, single life; *cœlebs* or *cælebs*, an unmarried person); the unmarried state. Scaliger derives the word from κοίτη, bed, and λείπω, to leave; and some more fancifully, from *cœli beatitudo*, *i.e.*, the blessedness of heaven.

Clearchus, a pupil of Aristotle, states that at a certain festival at Sparta, the women were enjoined to flog old bachelors around an altar, that they might be constrained to take wives.

The ancient Romans enacted various laws to discourage celibacy. Dionysius Halicarnasseus mentions an ancient constitution by which all persons of mature age were obliged to marry. But the first law of that kind of which we have any certain information is that under Augustus, called *Lex Julia de Maritandis Ordinibus*. It was afterwards denominated *Papia Poppœa*, and more usually *Julia Papia*, on account of some new sanctions and amendments made to it under the consuls Papius and Poppæus. By this law various prerogatives were given to persons who had many children; while penalties were imposed on those who lived a single life, such as being incapable of receiving legacies, unless they married within the space of a hundred days from the testator's death.

CELIBATE, the same with celibacy; but it is chiefly used with reference to the single life of the Popish clergy, or the obligation they are under to abstain from marriage. In this sense we speak of the law of *celibate*. Monks and religious persons take a vow of celibate, and of chastity.

The Church of Rome imposes celibacy on all its clergy, from the pope to the lowest deacon and subdeacon. The advocates for this usage pretend that a vow of perpetual celibacy was required in the ancient church as a condition of ordination, even from the earliest apostolic ages. But the contrary is evident from numerous examples of bishops and archbishops who lived in a state of matrimony, without prejudice to their ordination or their function. It is generally agreed that most of the apostles were married; some say all of them, except St Paul and St John. In the ages immediately succeeding the apostles, we have accounts of many married bishops, presbyters, and deacons, without any reproof or mark of dishonour being set on them: for instance, Valens, presbyter of Philippi, mentioned by Polycarp; and Chæremon, bishop of Nilus. Novatus was a married presbyter of Carthage, as we learn from Cyprian, who himself was also a married man, as Pagi confesses; and so was Cæcilius, the presbyter who converted him, and Numidius, another presbyter of Carthage. The reply which the Romanists give to this is, that all married persons when they came to be ordained promised to live separate from their wives by consent, which answered the vow of celibacy in other persons. But this is not only said without proof, but against it; for Novatus, presbyter of Carthage, was certainly allowed to retain his wife after ordination, as appears from the charge which Cyprian brings against him, that he had struck and abused his wife, and thereby caused her to miscarry. There seems indeed to have been in some cases a tendency towards the introduction of such a law by one or two zealots; but the motion was no sooner made than it was quashed by the authority of wiser men. Thus Eusebius observes, that Pinytus, bishop of Gnossus in Crete, was for laying the law of celibacy upon his brethren; but Dionysius, bishop of Corinth, wrote to him that he should consider the weakness of men, and not impose that heavy burden on them. In the council of Nice, A.D. 325, the motion was renewed for a law to oblige the clergy to abstain from all conjugal intercourse with their wives whom they had married before their ordination; but Paphnutius, a famous Egyptian bishop, and one who himself was not married, vigorously declaimed against it,—upon which it was unanimously rejected. The story is thus told by Socrates and Sozomen; and all that Valesius, after Bellarmin, has to say against it is, that he suspects the truth of it. The council of Trullo, held in 692, made a difference in this respect between bishops and presbyters; allowing presbyters, deacons, and all the inferior orders, to live with their wives after ordination; and giving the Roman church a smart rebuke for the contrary prohibition, but at the same time laying an injunction upon bishops to live separate from their wives, and appointing the wives to betake themselves to a monastic life, or become deaconesses in the church. And thus was a total celibate established in the Greek church as to bishops, but not as to any others. In the Latin church a similar rule was established, but by slow degrees in many places; for in Africa even bishops cohabited with their wives at the time of the council of Trullo. The celibacy of the clergy, however, appears of ancient standing, and if not of command and necessity, yet of counsel and choice. But as it is clearly neither of divine nor apostolical institution, it is not easy at first view to conceive from what motive the court of Rome could have persisted so obstinately in imposing this institution on the clergy. But we are to observe that this was a leading step to the execution of the project formed of making the clergy independent of princes, and rendering them a separate body to be governed by their own laws. In effect, while priests had children it was difficult to prevent their dependence on princes, whose favours have such an influence on private men; but having no family they were more at liberty to adhere to the pope. That ambitious pontiff Gregory VII., perceiving the great advantages in these respects that must accrue to the church, enforced the laws of celibacy with unbending rigour.

CELIDOGRAPHIA, a description of the spots on the disc of the sun, or of planets.

CELL (*cella*, from *celare* to conceal), in ancient writers, a place or apartment, usually under ground, and vaulted, in which were stored up wine, honey, oil, and provisions generally; and according to which it was called *cella vinaria*, *mellaria*, *olearia*, &c. Cella also denoted a room in a brothel, as being anciently in underground vaults, and hence also denominated *fornix*. It was also applied to the dormitories of slaves and menials. Cicero, inveighing against the luxury of Antony, says, the beds in the very cellæ of his servants were spread with pompous purple coverlets. The word was further applied to the apartments of baths. Of these there were three principal ones, *frigidaria*, *tepidaria*, and *caldaria*. See BATHS. It likewise signified the *adytum*, or part of a temple in which the image of the god stood.

Cella was also used for a lesser or subordinate monastery dependent on a great one. Most of the great abbeys in England had *cells* in places distant from the mother abbey. The alien priories in England were cells to abbeys in Normandy, France, or Italy. The name of *cell* was sometimes applied to independent monasteries.

CELL signifies also a small apartment or chamber, such as those in which monks and hermits live in retirement. Some derive the word from the Hebrew כלא a prison. The hall in which the Roman conclave is held is divided by partitions into different cells, for the use of the cardinals.

CELLAR (*cellarium*), in ancient writers, the same with cella, namely, a conservatory of provisions or liquors.

CELLAR now denotes an apartment under a house or other building, used as a repository of liquors, provisions, or other stores.

CELLARER, or CELLERER (*Cellerarius* or *Cellarius*), an officer in monasteries, to whom belonged the care and procurement of provisions for the convent.

The *cellerarius* was one of the four *obedientiarii*, or great officers of monasteries. Under his orders were the *pistrinum* or bakehouse, and the *bracinum* or brewhouse. In the richer houses there were particular lands set apart for the maintenance of his office. The *cellerarius* was an impor-

tant person in the convent. He was bound to see his lord's corn got in and stored; and his appointment consisted in a certain proportion of grain, usually a thirteenth part of the whole, together with a furred gown. He had also the receipt of his lord's rents throughout the whole extent of his jurisdiction. (See Chronicle of Jocelyn of Brakelonde.)

CELLARIUS, CHRISTOPHER, was born in 1638, at Smalcald in Franconia, of which town his father was minister. He took a doctor's degree at Jena, and was professor of Hebrew and moral philosophy at Weissenfels. He was afterwards rector of the colleges at Weimar, Zeitz, and Merseburg; and ultimately became professor of rhetoric and history in the college of Halle, founded by the king of Prussia. In this latter place he composed the greater part of his works. His great application to study hastened the infirmities of old age, and brought on his death in 1707.

His principal works are, I. Philological; *Antibarbarus Latinus*, Cizæ, 1677; *Orthographia Latina*, Jenæ, 1704; *Curæ posteriores de Barbarismis, &c., Sermonis Latini*, Jenæ, 1700; *Grammatica Hebræa*, Jenæ, 1699; *Chaldaismus*, Cizæ, 1685; *Rabbinismus*, ibid., 1684; *Isagoge in Linguam Arabicam*, ibid., 1678; *Porta Syriæ*, and *Porta Syriæ patentior*, Cizæ, 1682. II. Historical; *Historia Antiqua*, Cizæ, 1685; *Historia Medii Ævi*, ibid., 1688; *Historia Nova*, Halæ, 1696. III. Geographical; *Notitia orbis antiqui*, Lips., 1701-1706; *Geographia antiqua*, Jenæ, 1691; *et nova*, ibid, 1709.

CELLINI, BENVENUTO, (1500-1570), was born at Florence, where his ancestors had long been known as architects and musicians. His father, who was a musician, designed him for the same profession with himself, and endeavoured to thwart the inclination of Benvenuto for sculpture and engraving. When he had reached the age of fifteen, his youthful predilection had become too strong to be resisted, and his father reluctantly gave his consent to his becoming apprenticed to a goldsmith. In this capacity he soon distinguished himself by his superior skill in chasing sword-handles, cutting dies, and engraving medals. He had already attracted considerable admiration in his native place, when, being implicated in a fatal fray with some of his companions, he was banished to Siena, from which he soon after removed to Rome. A beautiful gold medal of Clement VII., of which he was known to have furnished the die, secured him a favourable reception at the papal court, and gained him abundant employment in cutting seals for his ecclesiastical patrons. On his return to Florence, his violent temper again embroiled him in a quarrel, which again compelled him to retreat in disguise to Rome. In the war with France, which broke out immediately after, the bravery and address of Cellini proved of signal service to the pontiff; and his exploits paved the way for a reconciliation with the Florentine magistrates, and his return shortly after to his native place. Here he assiduously devoted himself to the execution of medals, the most famous of which are Hercules and the Nemean lion, and Atlas supporting the sphere. From Florence he went to the court of the Duke of Mantua, and thence again to Rome, from which he quickly fled to Naples to shelter himself from the consequences of a duel in which he was a party. Through the influence of several of the cardinals he obtained a pardon; and on the elevation of Paul III. to the pontifical throne he was reinstated in his former dignities, notwithstanding a fresh homicide which he had committed in the interregnum. Once more the plots of Pier Luigi, a natural son of Paul III., led to his retreat from Rome, and once more he was restored with greater honour than before. On returning from a visit to the court of Francis I., he was imprisoned on a charge of embezzlement during the war, but was liberated at the intercession of Cardinal Bembo, to whom he presented a splendid cup. For a while he wrought at the court of Francis I.; but the intrigues of the king's favourites, whom he would not stoop to conciliate, and could not venture to silence by the sword, as he had his enemies at Rome, led him to retire in disgust to Florence, where he employed his time in works of art. During the war with Siena, Cellini was appointed to strengthen the defences of his native city, and continued to gain the admiration of his fellow-citizens by the magnificent works which he contributed for its decoration. He was buried with great pomp in the church of the S. Annunziata. Besides the works in gold and silver which have been alluded to, Cellini executed several pieces of sculpture on a grander scale. The most distinguished of these is the bronze group of Perseus cutting off the head of Medusa, placed in front of the old ducal palace at Florence. Nothing, however, is more highly characteristic of Cellini than his autobiography, in which his adventures, pursuits and passions are depicted with the utmost *naiveté* and good humour. It has been translated into English by Thos. Roscoe. Several of Cellini's writings, however, still exist in manuscript.

CELSUS, AURELIUS CORNELIUS, a very celebrated physician of the first century, and author of a treatise *De Medicina*, in eight books. See ANATOMY and SURGERY.

CELTÆ, in Greek Κελται, CELTES, or CELTS, or KELTS, an ancient nation, by which most of the countries in Europe appear to have been occupied at a period anterior to the commencement of history.

When the Greek and Roman writers first began to turn their eyes westward, they found Europe, from the extremity of Ireland to the banks of the Danube, peopled by a race called Gauls, or Celts, or rather Kelts, who, before they became bound to the soil by tillage, had overspread part of Spain in the course of their armed migrations, and had even poured their predatory bands through the Alpine passes, into the great plain of northern Italy. They extended along the Danube, as far as the Euxine, and spread themselves till they were met on different sides by the Sarmatians, Thracians, and Illyrians. Their expeditions were in general prior to the period of history; and we have but slender means of probable conjecture as to the antiquity, extent, and direction of the great migratory movements of this remarkable race.[1]

At that era, indeed, when the dawn of history begins to dispel the dark cloud which had overshadowed the early ages of the world, we find the different races of people in Europe occupying nearly the same relative situations as at present; and, even in the oldest memorials, we can scarcely discern a trace of those wanderings or migrations of tribes which must nevertheless have originally filled this region of the earth with inhabitants.[2] From a remote antiquity, the whole of the country between the Euxine and the German Ocean appears to have been possessed by the Cimmerii or Cimbri, one of the grand divisions of the Celts; while Gaul was occupied by the other division, to which the name of Celtæ was more properly and commonly applied.[3] Herodotus mentions the Celts and Cynetæ as inhabiting the remotest parts of Europe, towards the setting of the sun, near the sources of the Ister or Danube; and it is unknown during how many ages they had occupied this region before the father of history obtained this, which is the earliest notice of them. Aristotle and other ancient writers give us nearly the same information with Herodotus, whom they probably followed. With regard to Britain, it must have been inhabited at a period anterior to the Trojan war, since, from the statement of Herodotus, it appears that tin exported from Britain by Phœnician traders was at that

[3] Pinkerton, *Dissertation on the Scythians or Goths*, part. i. chap. 2.

time in general use; a circumstance which seems to imply that our island was then peopled by a race who had already explored its metallic treasures; whilst, from other considerations, it has with much probability been inferred that the earliest settlers or inhabitants of Britain were of Celtic origin. At a period not long subsequent to the age of Herodotus, the Teutonic nations inhabited the north of Europe. Pytheas of Marseilles, contemporary with Aristotle, mentions the Guttones, who inhabited the shores of an estuary which must have been the mouth of the Vistula, and carried on a traffic in amber with their neighbours the Teutones,[1] then well known under that appellation; and as the Guttones were probably Goths, we thus already discern in the north of Europe two of the most celebrated nations belonging to the Germanic family, in an age when the name of Rome had scarcely become known to the Greeks. The Finns and Sclavonians are supposed to have been the latest of the great nations who formed the population of Europe. Finningia and the Fenni are mentioned both by Tacitus and by Pliny. In the age of these writers the Finns were situated near the eastern shores of the Baltic, and had probably extended themselves as far as those districts where their descendants were afterwards known under the name of Beormas or Biarmiers. The Sclavonians are not early distinguished in Europe under that name; but the appellation of Wends, given to the Sclavonic race by the Germans, seems to identify them with the Venedi mentioned in the geographical descriptions of Pliny and Tacitus, as also with the Ουενεδαι or Winidæ of Ptolemy and Jornandes, these being terms appropriated to the Sclavonic nations. Besides, it is probable that the Russians were known to Herodotus, and that they are mentioned by him under an appellation differing but little from that which is now applied to them by their Finnish neighbours. The Rhoxolani, first described by Herodotus, are stated by Strabo to have inhabited the plains near the sources of the Tanais and Borysthenes; and the Finns still distinguish the Muscovites by the name of Rosso-lainen, or Russian people, a term which, if heard by a Greek, would naturally be written Rhoxolani.[2]

It thus appears that the European races, in the earliest periods of which we have any information respecting them, occupied nearly the same relative situations as the tribes chiefly descended from them still continue to possess. The few scattered facts or intimations which history furnishes, therefore, afford no evidence against the hypothesis that different parts of the world were originally filled with autochthones or indigenous inhabitants, nor indeed against any other hypothesis or theory whatsoever. Great reliance has been placed by many upon traits of resemblance in customs and superstitions; and from the coincidence of the doctrines of druidism and the mythology of the Sagas, some have ascribed a common origin to the nations of Europe and those of the East. But this principle is exceedingly unsafe; for by a similar mode of reasoning we might conclude that the Turks and Tartars came from Arabia, and derive the Buddhists of Northern Asia from India, or perhaps from Ceylon. Nor can historical traditions, however plausible and striking these may in some instances appear, fill up the void; because, besides involving every element of error, they are found, when examined and compared, to lead to contradictory and incompatible results. It is, therefore, only by an analysis of languages, which, after all, are in reality the most durable of human monuments, and by detecting in their composition common elements and forms of speech, that we can ever hope to obtain satisfactory evidence of the identity or connection in point of origin of those races by which they are spoken with ancient nations whose languages have been preserved either in whole or in part.

The diversity of opinion which has hitherto prevailed on this subject proves the uncertainty and insufficiency of the data from which inquirers have hitherto deduced their conclusions. Among the ancients the notion that each particular region of the earth was from the beginning supplied, by a distinct creation, with its peculiar stock of indigenous inhabitants, seems to have prevailed universally; and the frequent recurrence of such terms as *autochthones*, *indigenæ*, and *aborigines*, affords undoubted evidence of the fact. In modern times, however, the very opposite opinion has been that most generally entertained; and all the nations of the earth have, on the authority of the sacred Scriptures, been referred to one common parentage. But of late years, many learned men, chiefly on the Continent, have evinced a strong inclination to adopt an opinion similar to that of the ancients; and the notion of radically distinct and separate races of men seems to be gaining ground among the naturalists and physiologists of France, as well as among the historians and antiquaries of Germany. Among the former there are some who speak of the Adamic race as of one among many distinct tribes, and others who broadly controvert its claims to be considered as the primary stock of the human race. On the other hand, some of the most learned of the Germans have divided man into five distinct *varieties*. Humboldt, notwithstanding the many evidences of intercourse between the inhabitants of the eastern and western continents, appears to regard the primitive population of America as a distinct variety of the race. Malte-Brun has plainly taken it for granted, that, from the earliest times, each part of the earth had indigenous inhabitants, into whose origin it is vain to make inquiries; and even Niebuhr, perplexed by his researches into the early history and population of Italy, is glad to escape from the difficulty of his subject by adopting a similar opinion. On the other side of the question, or what may be called the Scriptural theory, names of equal celebrity may be cited, including that of Sir William Jones, which is in itself a host. But this subject is not one which can be decided either way by authority; and it is only by examining the evidence which seems to bear more immediately on the subject that we can ever hope to arrive at a satisfactory conclusion. This, viewed generally, is of two kinds, and comprises, first, considerations resulting from a survey of the natural history of the globe, and facts connected with physical geography and with the multiplication and dispersion of species of both plants and animals; and, secondly, analytical investigations into the structure, affinities, and diversities of languages, in reference to the general question as to the history of our species. With regard to the arguments deduced from the former source, however, although they may at first view appear to bear with the greatest weight upon this question, yet, from our inability duly to appreciate the effects of physical causes operating during a course of ages indefinitely great, it is impossible, with any degree of certainty, to infer original distinction from the actual differences observable among mankind. But in the case of languages, especially those which, though they have ceased to be spoken, are still preserved, there is no such element of uncertainty; and hence we are inclined to hold, that the only conclusions on which we can safely rely respecting the aboriginal history of our species, are those deducible from an analysis of languages conducted on strict philosophical principles.

[1] Plin. *Hist. Nat.* lib. xxxvii. cap. 2.

[2] Pritchard *on the Celtic Nations*, p. 16.

Such an analysis of various languages as that here spoken of will in every instance display one or other of four different relations subsisting between them. 1. In comparing some languages, little or no analogy can be discovered in their grammatical structure, but a resemblance more or less extensive may be traced in their vocabularies, or in the terms for particular objects, actions, and relations; and if this correspondence is the result of commercial intercourse, conquest, or the introduction of a new system of religion, literature, and manners, it will extend only to such words as belong to the new stock of ideas thus introduced, and will leave unaffected the great proportion of terms which are expressive of more simple ideas and of universal objects; but if the correspondence traced in the vocabularies of any two languages is so extensive as to involve words of a simple and apparently primitive class, it indicates a much more ancient and intimate connection. 2. Certain languages, which have but few words in common, nevertheless display, when carefully examined, a remarkable analogy in their principles and forms of grammatical construction; as in the polysynthetic idioms of the American tribes, and the monosyllabic languages of the Chinese and Indo-Chinese nations. 3. A third relation discoverable between languages, connected by both the circumstances already pointed out, consists in what may be properly called cognation; an epithet which is applied to all those dialects which are connected by analogy in grammatical forms, and by a considerable number of primitive words or roots common to all, or which at least possessed such a resemblance as manifestly indicates a common origin. 4. The fourth and last relation, which is almost purely negative, exists between languages in which none of the connecting characters above described can be discerned, and there is discoverable neither analogy of grammatical structure, nor any correspondence in words, sufficient to indicate a particular affinity; circumstances which are held as conclusive that such languages are not of the same family, and that they belong to nations remote from each other in descent as well as differing in physical characteristics.[1]

Upon these principles, which are now universally received as almost the only guides in investigating the origin and descent of nations, the languages of the Finnish tribes, the Laplanders, the Hungarians, the Ostiaks, and the Siberian Tschudes, have been compared and analysed by Gyarmathi, Adelung, Gatterer, Klaproth, and others; and the result, which appears to have been sufficiently established, is, that all these nations have sprung from one common original stock, the primitive seat of which was the country situated between the chain of Caucasus and the southern extremities of the Uralian Mountains. But our chief concern at present is with those tribes which have been latterly denominated Indo-European; a term which includes all that class of nations, many of them inhabitants of Europe, whose dialects are more or less nearly related to the ancient language of India. The idea of this classification, which is by far the most scientific that has yet been adopted, was suggested by comparing the Sanscrit with the Greek and Latin languages, and observing the interesting and remarkable results evolved by the comparison. These were, first, the detection of a very considerable number of primitive words, which were found to be common to all these languages; and, secondly, the discovery of a still more striking affinity which was proved to exist between their respective grammatical forms. In the case of the Greek and the Sanscrit this affinity amounts almost to complete identity; in that of the Latin and Sanscrit, it is also, as might be supposed, exceedingly striking; and these languages are all evidently branches of one common or parent stem. But the same process of analysis has led to other and not less curious or interesting results. It has been proved that the Teutonic as well as the Sclavonic, including the Lettish or Lithuanian, stand in nearly the same relation to the ancient language of India as the Greek and Latin; and several intermediate languages, as the Zend and other Persian dialects, the Armenian, and the Ossete, which is one of the various idioms spoken by the nations of the Caucasus, have been held, by those who have examined their structure and etymology, to belong to the same stock.[2] In this way, a close and intimate relation was proved, by unquestionable evidence, to subsist between a considerable number of languages and dialects used or spoken by nations who are spread over a great part of Europe and of Asia, and to them the term Indo-European has in consequence been applied. In fact, the more accurately these languages have been examined, the more extensive and deep-rooted have their affinities appeared; and it is only necessary to refer to Professor Jacob Grimm's masterly analysis of the Teutonic idioms, to enable the reader to verify the truth of this remark. The historical inference deducible from these investigations, therefore, is, that the European nations who speak dialects referrible, on analysis, to this class or family of languages, are of the same race with the Indians and Asiatics, to whom a like observation may be applied; and that all are the descendants of some original nation or people who spoke the primitive language, to which all the Indo-European forms of speech may be referred as a common source.

But a more immediate subject of inquiry is, whether the Celtic dialects belong to the class or family of languages thus allied and denominated; and the question is the more interesting as it bears directly on the origin of the nations of western Europe, including the British islands, as well as on the more extensive one relating to the physical history of mankind. Many have supposed the Celts to be of oriental origin, but, for the most part, on grounds which are either altogether fanciful, or at least insufficient to warrant such a conclusion. The compilers of the *Universal History*, for instance, gravely tell us that the Celts were descended from Gomer, the eldest son of Japhet, the son of Noach; that Gomer settled in the province of Phrygia in Asia Minor, while his sons Ashkenaz and Togarmah occupied Armenia, and Riphath took possession of Cappadocia; that when they found it necessary to spread themselves wider, they moved regularly in columns, without disturbing or interfering with their neighbours; that the descendants of Gomer or the *Celtæ* took the left hand, and gradually spread themselves westward to Poland, Hungary, Germany, France, and Spain; and that the descendants of Magog, the brother of Gomer, moved to the eastward, peopling Tartary, and spreading themselves as far as India and China. Speculative fancies like these, however, are too absurd and extravagant to be even amusing. The real question is, whether the same arguments which prove most of the other nations of Europe to be of eastern origin and descent, may not also be applied to that great stock, the branches of which, at a period anterior to the commencement of history, had overspread Gaul, Britain, and occupied a considerable portion of Spain.

But here it is proper to observe, that writers on the his-

[1] Pritchard *on the Celtic Nations*, pp. 9, 10. Kennedy's *Researches into the Origin and Affinity of the Languages of Asia and Europe*, p. 80. *Edinburgh Review*, No. cii. p. 560.

[2] Klaproth, *Asia Polyglotta.*

tory of languages and the antiquity of nations are divided in opinion with respect to this question. Adelung and Murray have considered the Celtic as a branch of the Indo-European stock; but the latter has left that part of his work which relates to the Celtic dialects in a most incomplete state; and Adelung has committed the error of supposing the Welsh or Cymric to be derived from the language of the Belgæ, and not from that of the Celtæ, who inhabited the central parts of Gaul and of Britain. From want of information respecting the Celtic dialects, many of the continental writers, among whom may be mentioned Frederick Schlegel and Malte-Brun, have been led to believe the Celtic to be a language of a class wholly unconnected with the other idioms of Europe; and in Britain the same opinion has, from the same cause, been expressed by several well-known authors. Mr Pinkerton, for instance, has declared, in his usual dogmatical manner, that the Celtæ were a people entirely distinct from the rest of mankind; and that their language, the real Celtic, is as remote from the Greek as the Hottentot from the Lapponic. And Colonel Kennedy, at the conclusion of the chapter in which he successfully refutes some of the opinions of Pelloutier and Bullet respecting the Celtæ and their language, concludes, that "the Celtic, when divested of all words which have been introduced into it by conquest and religion, is a perfectly original language;" and that "this originality incontrovertibly proves that neither Greek, Latin, or the Teutonic dialects, nor Arabic, Persian, or Sanskrit, were derived from the Celtic, since these languages have not any affinity whatever with that tongue."[1] Davis, however, in the preface to his Dictionary, had said, "Ausim affirmare linguam Britannicam (Celticam) tum vocibus, tum phrasibus et orationis contextu, tum litterarum pronunciatione, manifestam cum orientalibus habere congruentiam et affinitatem;" and the result of a more accurate and minute analysis has been to confirm this opinion in the most complete manner possible.

The connection of the Sclavonian, German, and Pelasgian races with the ancient Asiatic nations may be established by historical proof. But the languages of these races, and the Celtic, although differing from each other, and constituting the four principal classes of dialects which prevail in Europe, are nevertheless so far allied in their radical elements, that they may with certainty be considered as branches of the same original stock. Remarkable indeed is the resemblance observable in the general structure of speech, and in those parts of the vocabulary which must be supposed to be the most ancient, as, for instance, in words descriptive of common objects and feelings for which expressive terms existed in the primitive ages of society. In fact, the relation between the languages above mentioned and the Celtic is such as not merely to establish the affinity of the respective nations, but likewise to throw light upon the structure of the Indo-European languages in general; and particularly to illustrate some points which had previously been involved in obscurity. This is clearly demonstrated by Dr Pritchard's ample and satisfactory analysis, which embraces almost every thing that can possibly enter into an inquiry of this nature. He examines the permutation of letters in composition and construction, the sandhi and samasa in Sanscrit, and shows that the same principles are discoverable in the Celtic dialects, particularly in the Welsh and in the Gaelic. He exhibits proofs of common origin in the vocabulary of the Celtic and other Indo-European languages, first, in the names of persons and relations; secondly, in the names of the principal elements of nature, and of the visible objects of the universe; thirdly, in the names of animals; fourthly, in verbal roots found in the Celtic and other Indo-European languages; and, fifthly, in adjectives, pronouns, and particles. He then proceeds to investigate the proofs of a common origin derived from the grammatical structure of the Celtic as compared with that of other Indo-European languages, particularly the Sanscrit, the Greek, the Latin, the Teutonic dialects, the Sclavonian dialects, and the Persian language; and in all of these he shows that a striking resemblance is discoverable in the personal inflections of verbs, as well as in the personal pronouns, and in the inflections of verbs through the different moods and tenses; and he concludes with a further illustration of the principles which he had previously established by an analysis of the verb substantive and the attributive verbs in the Celtic dialects, and in other Indo-European forms of speech, the result of which is to evolve coincidences precisely analogous to those already exemplified with the utmost accuracy of detail. What, then, is the legitimate inference to be deduced from the obvious, striking, and, we may add, radical analogies here proved to exist between the Celtic dialects and the idioms which are generally allowed to be of cognate origin with the Sanscrit, the Greek, and the Latin languages? The marks of connection are manifestly too decided and extensive, and enter too deeply into the structure and principles of these languages, to be the result of accident or casual intercourse; and being thus interwoven with the intimate texture of the languages compared, seem incapable of explanation upon any principle except that which has been admitted with respect to the other great families of languages belonging to the ancient population of Europe; namely, that the whole Celtic race is of oriental origin, and a kindred tribe with the nations who settled on the banks of the Indus, and on the shores of the Mediterranean and the Baltic. It is probable, indeed, that several tribes emigrated from their original seat at different periods and in different stages of advancement in respect to civilization; and hence we find their idioms in different stages and degrees of refinement: but the proofs of a common origin, derived from an accurate examination and analysis of the intimate structure and component materials of these languages, are nevertheless such as, in our judgment, must command general assent; more especially considering that the general inference thus deduced receives strong confirmation from those purely physical investigations to which we have already alluded. If, indeed, there be any truth in those principles of classification which naturalists have adopted, the Mongol, the Chinese, the Hindu, and the Tartar, are not more certainly oriental than the native Celt, whose physical conformation exhibits only a slight modification of that which is peculiar to the great race whence he is descended; while his superstitions, manners, customs, and observances, as well as language, are all decidedly marked with traces and indications of an eastern origin.

With respect to the form of government which prevailed among the Celts, we are left in some measure to conjecture. It seems, however, to have partaken somewhat of the character of a theocracy, which, with great powers of adaptation to circumstances, generally maintained a complete ascendency. The druids, assisted by the bards, were the guardians and interpreters of their laws, as well as the ministers of their religion; they judged all causes, whether civil or criminal; and their sentence was reckoned so sacred, that whoever refused to abide by it was excluded from assisting at their rites, denied the use of fire, and intercommuned or interdicted from all con-

[1] Kennedy's *Researches*, p. 85. Pritchard's *Celtic Nations*, pp. 20, 22.

verse with his fellow-men. Indeed, the law of caste, in as far as the sacred order was concerned, appears to have been inveterate and indelible; and hence Sir James Mackintosh, without going into any inquiry respecting the origin and descent of this singular race, justly remarks that the druidical system is not without oriental features. The Celts, however, erected neither temples nor statues to the Deity, but, on the contrary, were fierce iconoclasts, destroying shrines and idols wherever they could find them. Instead of these they planted spacious groves, which, in their opinion, were more acceptable to the Deity, who is absolutely unconfined, than houses made with human hands; and amidst the depth and gloom of umbrageous forests, the druids celebrated their holy mysteries, and, as is generally believed, offered up human sacrifices. They were perfectly inexorable to mere idolaters; in which respect their religion bore a resemblance to that of the Parsees and the disciples of Zoroaster. It differed, however, in their making the oak instead of the fire the emblem of the Deity, and in their choosing that tree in preference to others to plant their groves withal, as well as in their attributing supernatural virtues to its wood, leaves, fruit, and particularly the mistletoe, all which were made use of in their sacrifices and other parts of their worship. But after they had adopted the idolatrous superstitions of the Romans and other nations, and particularly admitted the apotheosis of their heroes and princes, they came to worship the latter much in the same manner as the people whose practice they followed; venerating Jupiter under the name of *Taran*, which in the Celtic signifies thunder, and also Mercury, whom some authors call *Heus* or *Hesus*, probably from the Celtic *handh*, which signifies a dog, a circumstance which has led some to consider him as identical with the *Anubis Latrans* of the Egyptians. Mars was held in the greatest veneration by the warlike, and Mercury by the trading part of the nation. The care of religion, as has already been stated, was immediately intrusted to the druids and bards, who, as Cæsar informs us, were the performers of sacrifices and all religious rites, and the expounders of religion to the people. They also instructed youth in all kinds of learning with which they were acquainted, as philosophy, astronomy, astrology, and the like. Their doctrines, however, were only taught orally, being esteemed as too sacred to be committed to writing. But more common subjects, such as hymns to their gods, and the exploits of princes and generals in time of war, were couched in a species of verse, and recited, or rather sung, on all proper occasions; though even these were kept from vulgar eyes, and either committed to memory, or, if to writing, withheld from the laity. Cæsar mentions that these poetical records had in his time increased to such a bulk that it took a young bard nearly twenty years to learn them by heart; and Diodorus says, that the poets or bards used to accompany their songs with instrumental music, on organs, harps, and the like; and that these minstrels were held in such veneration, that if in the time of an engagement between two armies one of the bards appeared, both sides immediately ceased fighting. The reason of this was, that they were universally believed to be prophets as well as poets, or, in other words, gifted with a double inspiration; and it was therefore thought dangerous as well as injurious to disobey what was supposed to emanate from the gods. These prophetic poets and philosophers kept academies, which were resorted to, not only by a great number of their own youth, but also by the youth of other countries; insomuch that Aristotle says their philosophy passed from them into Greece, and not from Greece to them. Diodorus likewise quotes a remarkable passage from Hecatæus, in which it is stated that the druids had some kinds of instruments by which they could draw distant objects nearer, and make them appear larger and plainer; and by which they could discover even seas, mountains, and valleys, in the moon. Can it be possible that this strange fraternity of priests were really in possession of the telescope? But whatever may have been their learning, it is certain, that in process of time they adopted several barbarous customs, such as that of sacrificing to their gods human victims, which they believed to be more acceptable to them than those of any other animals. Another inhuman practice which they observed in their divinations, especially on great matters, consisted in killing some of their slaves, or some prisoners of war if they had any, with a scimitar, in order to draw an augury from the manner in which the blood flowed from the mangled limbs of the victim.

Such is a brief sketch of the origin of the Celts, and of the more prominent peculiarities by which they were distinguished in ancient times. As a subordinate race, or rather as a more ancient offset from the parent stock, they were inferior to the Scythians or Goths, and generally yielded, though not without a gallant struggle, to the incessant pressure of the mighty tide of emigration which, from a very early period, flowed from the north towards the south and west of Europe, and which at length overwhelmed the Roman empire, burying in its ruins the civilization of fourteen centuries. (J. B—E.)

CELTES, ancient instruments of a wedge-like form, found in different parts of Great Britain, and which, on the supposition that they were weapons of the Celtæ, have received the above unmeaning appellation. Whitaker and other antiquaries, however, are of opinion that they were British battle-axes. See *Battle-Axe*.

CELTIBERIA, the country of the Celtiberi, was an extensive inland division of Spain, stretching from the mountains Indubeda and Orospeda westwards to the sources of the Tagus, the Douro, and Guadiana, and comprehending the modern provinces of Cuença and Soria, part of Aragon and part of Burgos. In the later times of the Roman empire, however, the name came to be almost synonymous with Hispania Citerior. It was a mountainous and barren region, intersected with valleys of great fertility and beauty, and containing some prosperous and celebrated cities. Of these the most famous were Segobriga, the capital; Numantia, which endured a siege of ten years from the Romans, and was only taken by the younger Scipio, B.C. 133; Bilbilis, the birthplace of the poet Martial, and many other towns of less note and importance. The inhabitants, as their name imports, were the descendants of the Celts who crossed the Pyrenees from Gaul, and settling in this part of Spain, intermarried with the aboriginal Iberians. They were characterized by the better qualities of both the races from which they sprang, and, as a people, were superior to either. Their valour and military skill were proved in their long and obstinate contest with the Romans, whom they not unfrequently defeated. These qualities were all the more formidable, as, unlike the surrounding tribes, the Celtiberi had brought their soldiers to a high pitch of discipline in their wars with their neighbours and the Carthaginians. They were at last subdued; and though they again revolted, they were unable to make head against the younger Scipio, after the destruction of Numantia. Under Sertorius they once more became formidable to the Roman empire in Spain; but after the fall of that general they quietly submitted, and do not appear again in history as a separate and independent people.

CEMENT. Any substance which is employed in uniting together things of the same or of different kinds may be termed a cement. The following are some of the principal of those used for various purposes.

To unite pieces of Derbyshire spar, or other stone, take

seven or eight parts of resin and one of wax; then melt them together, and mix them with a small quantity of plaster of Paris. The stone should be made sufficiently hot to melt the cement, and the pieces should be pressed so closely together that the smallest quantity possible of the cement may remain between them. It is a rule of general application, that the thinner the stratum interposed the firmer the junction will be.

Jewellers unite precious stones which have been accidentally broken, by means of gum-mastic. The parts of the gem must be previously heated to a degree sufficient to melt the cement. Cameos of white enamel or coloured glass are also in this way joined to a real stone as a ground. Mastic is likewise employed by jewellers in various ways as a cement. The jewellers in Turkey ornament trinkets and weapons with gems, by uniting them together with the following composition:—Isinglass, soaked in water till it swells up and becomes soft, is dissolved in French brandy or rum, so as to form a strong glue; then two small bits of gum galbanum, or gum ammoniacum, are dissolved in two ounces of this by trituration; and five or six pieces of mastic about the size of peas are to be dissolved in as much alcohol as will render them fluid, and mixed with the compound by means of a gentle heat. This cement must be kept in a phial closely stopped; and when used it must be liquefied by immersing the phial in warm water. It will be found to resist moisture.

As a cement for broken china, take quicklime and white of eggs, or thick old varnish; pound and temper them well together, and the composition is ready for use. Broken glass may be cemented in the following manner:—Let glass which is more easy of fusion than the parts to be united, be ground up like a pigment, and interposed between the pieces; then let these be subjected to a heat which will melt the cementing medium, and make the parts agglutinate without being themselves fused. Anything thus united will be found nearly as strong as ever.

If clay and oxide of iron be mixed with oil, they will form a cement which hardens under water. A cement insoluble in water is prepared from skimmed milk cheese. The cheese is cut into slices, the rind being thrown away, and boiled till it becomes a strong glue, which, however, does not dissolve in the water. It is to be afterwards washed in cold, and then kneaded in warm water. This process must be several times repeated. The glue is then to be put warm on a levigating stone, and kneaded with quicklime. Though this cement may be used cold, it is best to warm it; and it will unite marble, stone, or earthenware, so as to render the joining scarcely discernible.

Boiled linseed oil, litharge, red lead, and white lead, mixed together and laid on both sides of a piece of flannel, or even linen or paper, and then put between two pieces of metal before they are brought home or close together, will make a durable joint, capable of resisting boiling water, or even a considerable pressure of steam. The proportions of the ingredients are not material; but the more the red lead predominates the sooner the cement will dry, and the more of the white lead the contrary. This cement joins stones of any dimensions.

The following is an excellent cement for iron, as it ultimately unites with it into one mass:—Take two ounces of muriate of ammonia, one of flowers of sulphur, and sixteen of cast-iron filings; mix them well in a mortar, and keep the powder dry. When the cement is to be used, take one part of this mixture, twenty parts of clear iron borings or filings, pound them together in a mortar, mix them with water to a proper consistence, and apply the compound between the joints.

A cement often used by coppersmiths to lay over the rivets and edges of the sheets of copper in large boilers, in order to serve as an additional security to the joinings. and to secure cocks and the like from leaking, is made by mixing powdered quicklime with ox's blood. This cement dries soon, and accordingly must be used fresh.

Temporary cements are required in cutting, polishing, or grinding optical glasses, and various articles of jewellery, as these must be fixed to blocks or handles for the purpose. Four ounces of resin, a quarter of an ounce of wax, and four ounces of whitening made previously red hot, forms a good cement of this kind, as the articles may be united or separated by heat, though they adhere with great tenacity when cold.

The following composition is recommended as a good cement for electrical apparatus:—Five pounds of resin, one of bees' wax, one of red ochre, and two table-spoonfuls of plaster of Paris, all heated together. The following is an analysis by Sir Humphry Davy of Roman or Parker's patent cement, which has the property of hardening under water.

One hundred grains contain

Silex	22
Alumina	9
Oxide of iron and manganese	13
Carbonate of lime	55
	99
One hundred grains lost by heating	3·25
	102·25

An excellent artificial water cement is obtained by heating for some hours to redness a mixture of three parts clay and one part slaked lime, by measure. (Ure's *Dictionary of Chemistry; Philosophical Magazine.*)

CEMENT *for Building*. See BUILDING, vol. iii., p. 742, and MASONRY.

CEMENTATION, the chemical process of effecting the combination of a metal and a cement by means of heat. Iron is converted into steel by cementation with charcoal; and common glass cemented with sand or with gypsum forms the porcelain of Reaumur. See STEEL, and PORCELAIN.

CEMETERY (*cœmeterium*, κοιμητήριον, from κοιμάω, to put to sleep), a place set apart for the burial of the dead. See MEDICAL JURISPRUDENCE; NECROPOLIS; BURIAL.

CENCI, BEATRICE DI, a noble Roman lady of the sixteenth century, whose beauty, sufferings, and tragical fate, have invested her name with a melancholy celebrity. The violence and cruelty of her father's character were notorious at Rome, and had long rendered him an object of terror to those whom fortune had placed within his power. Stained with crimes of the darkest hue, Count Cenci had purchased pardon from the government on various occasions by the sacrifice of enormous sums of money and portions of his estates; and, indeed, he appears to have been regarded by the state as "a certain and copious source of revenue." On the Sabine hills, about three miles N.E. of Borgo San Pietro, stands the castle of Petrella, in one of the most wild and desolate spots on the Neapolitan frontiers; and here Count Cenci retired during the heats of summer with his family, consisting of Beatrice, Bernardo, her youngest brother, and her stepmother Lucrezia. The loneliness of this place was well suited for the indulgence of his malignant and vindictive spirit, which wantoned in every species of cruelty that ingenuity could devise to aggravate the miseries of his long persecuted family.

> "That savage rock, the castle of Petrella,
> 'Tis safely wall'd and moated round about:
> Its dungeons underground, and its thick towers
> Never told tales; though they have heard and seen
> What might make dumb things speak."

The surpassing beauty of Beatrice, now on the verge of womanhood, excited in the breast of this unnatural parent feelings at which nature shudders; and to this crime was

added every circumstance of violence and cruelty. The attempts of his victim to escape by flight were frustrated by his vigilance; and Beatrice sunk into the lethargy of despair. The accumulated villanies of Count Cenci having at length aroused the vengeance of his wife, she conspired with the steward of the castle and several other persons to destroy their common tyrant. They accomplished their purpose by means of a hired assassin; and in order that the fatal wound might appear the result of accident, the body of the count was thrown from the walls among the branches of a jagged tree that grew in the fosse. Suspicions, however, being excited, the unhappy Cenci were apprehended, sent to Rome, and consigned to the castle of St Angelo, where they were subjected to tortures of the most frightful description. Beatrice, in the midst of her protracted sufferings, maintained the most heroic firmness; and even when suspended by her long and beautiful hair, her fortitude remained unshaken. Moved at last, however, by the entreaties of her relations to relieve them from their sufferings, she yielded so far as to reply to each interrogation of the judge—"*E vero*,"—adding, "O God, thou knowest if this be true." On this admission she was condemned to death.

The excitement caused in Rome by this decision was extraordinary. Many of the most illustrious families besought Clement VIII. (Aldobrandini) to reconsider the case; and some of the ablest advocates undertook to prove her innocence. But all their attempts to move compassion in the breast of the stern pontiff were unavailing. Counter influences, too, were at work; for the temptation of the princely possessions of the Cenci were too strong to be resisted by some who had an interest in the total extinction of her line. Beatrice was beheaded on the 11th September 1599. On the scaffold, when the executioner bound her hands she said—"You bind my body for destruction, but free my soul for immortality." A vast concourse of people assembled on the occasion, deeply commiserating the fate of one so young and gentle, a being "formed to adorn and be admired." More than one attempt was made to rescue her, and many lives were lost in the fray. In the church of San Pietro in Montorio, and before the high altar, were interred the remains of the beautiful, the noble-minded, the ill-fated Beatrice Cenci.

For a long period the MSS. recording these details were preserved with scrupulous secrecy, on account of the connection of the Cenci with many of the most illustrious houses in Rome; and it is only within a few years that they have been made accessible. A complete English version of this terrible tragedy, entitled *The True Story of Beatrice Cenci*, is to be found in Whiteside's *Italy*, vol. ii. pp. 128–72. In the Palazzo Barberini at Rome is preserved Guido's celebrated portrait of Beatrice, taken just before her execution. The story of the Cenci has been dramatized with great power by Shelley; who has, however, used a poet's license in implicating Beatrice unjustly in the guilt of her family.

CENEDA, a town of Venetian Lombardy, province and 27 miles north of the town of Treviso. It is the seat of a bishopric, and has a cathedral, several churches, episcopal gymnasium, seminary, and manufactures of woollens, paper, and leather. Pop. 5000.

CENEGILL, in Saxon antiquity, an expiatory mulct paid by one who had killed a man to the kindred of the deceased. The word is compounded of the Saxon *cinne*, relation, and *gild*, payment.

CENOBITE. See Cœnobite.

CENOTAPH (*cenotaphium*, from κενὸς, *empty*, and τάφος, *a tomb*), an empty tomb erected as a memorial of some person deceased; a funeral monument in honour of one buried elsewhere. Among the Greeks and Romans cenotaphs were erected as memorials of persons who had received the rites of sepulture elsewhere, as well as of those whose bodies were not found for burial at all. A common sign by which honorary sepulchres were distinguished was the wreck of a ship, to indicate the decease of the person in a foreign land.

CENSER, a vase containing incense to be used in sacrifices. Among the Greeks and Romans it was called *thuribulum*, λιβανωτρίς, and *acerra*. See Acerra.

The Jewish censer was a small sort of chafing dish, sometimes furnished with a handle, and probably of various shapes. The Jewish censers appear to have been unlike those of the classical ancients, with which the sculptures of Greece and Rome have made us familiar; as well as those (with perforated lids and swung by chains) used in the Church of Rome. Josephus tells us that Solomon made 20,000 golden censers for the temple of Jerusalem, and 50,000 others to carry fire in.

CENSIO, in *Antiquity*, the act or office of censor, which included both the valuation of a man's estate and the imposition of mulcts and penalties. See Censor.

CENSITUS, a person censed or entered in the tables of the census. In an ancient monument found at Ancyra, containing the actions of the Emperor Octavius (Augustus), we read—

> Quo lustro civium Romanorum
> Censita sunt capita quadragies
> Centum millia et sexaginta tria:

or that the number of Roman citizens entered in the censor's rolls was then upwards of 4,000,000.

Censitus is also used in the civil law for a servile sort of tenant who pays capitation to his lord for the lands he holds of him. See *Capite Censi*.

CENSOR (from *censere*, to estimate or judge), the title of two magistrates of high authority in the Roman republic. It was their duty to take a *census* or register of the effects of the citizens, to impose taxes in proportion to what each man possessed, and to superintend the public morals. In virtue of this last part of their office they had authority to censure vice and immorality, by inflicting some public mark of ignominy on the offender. They had even a power to create the *princeps senatus*, and to expel from the senate such as they deemed unworthy of that office. But this power they sometimes exercised without sufficient grounds; and therefore a law was at length passed that no senator should be degraded or disgraced in any manner until he had been formally accused and found guilty by both the censors. It was also a part of the censorial jurisdiction to fill up the vacancies in the senate, upon any remarkable deficiency in their number; to let out to farm all the lands, revenues, and customs of the republic; and to contract with artificers for the charge of building and repairing the public works and edifices, both in Rome and the colonies of Italy. In all parts of their office, however, they were subject to the jurisdiction of the people; and an appeal always lay from the judgment of the censors to that of an assembly of the people.

The first two censors were created in the year of Rome 311 (B.C. 442), upon the senate observing that the consuls were so much occupied with war as not to have time to look into other matters. The office continued to the time of the emperors, who assumed the censorial power, calling themselves *morum præfecti*; though Vespasian and his son took also the title of censors. Decius attempted to restore the dignity to a particular magistrate. But after this we hear no more of it till the time of Constantine, who made his brother censor; and he seems to have been the last who filled the office.

The office of censor was so considerable, that for a long time no one aspired to it till he had passed all the rest; and hence it was thought aspiring in Crassus to seek to be admitted as censor without having been either consul or prætor. At first the censors enjoyed their dignity for five

years; but in B.C. 433 the dictator Mamercus made a law restraining it to a year and a half, which was afterwards observed very strictly. At first one of the censors was elected from a patrician and the other from a plebeian family; and upon the death of either the other was discharged from his office, and new censors were elected, though not till the next lustrum. In the year B.C. 132, both censors were chosen from among the plebeians; and after that time the office was shared between the senate and the people. On their election in the *comitia centuriata*, the censors proceeded to the capitol, where they took an oath not to be guided either by favour or disaffection, but to act equitably and impartially throughout the whole course of their administration. See CENSUS.

CENSORS *of Books*, persons authorized in different countries to examine all publications before they go to press, that they contain nothing contrary to faith and good manners. In England there was formerly an officer of this kind under the title of licenser of the press; but since the Revolution our press has been laid under no such restraint. See BIBLIOGRAPHY.

CENSORINUS, a grammarian and philosopher of the third century, known by his treatise *De Die Natali*, which was written about the year 238, and is of considerable importance in regard both to the chronology and astrology of antiquity. It was first printed at Bologna in 1497, folio, with two fragments by unknown authors, entitled *Indigitamenta* and *De Naturali Institutione*. But the best editions are those of Havercamp, Leyden, 8vo, 1743, reprinted in 1767, and that of Gruber, 8vo, Nuremberg, 1805.

CENSURE, a judgment which condemns some book, person, or action. An ecclesiastical censure is a sentence of condemnation or penalty inflicted on a member of the church for mal-conduct, whereby he is deprived of the communion of the church, or prohibited from exercising the sacerdotal office.

CENSUS is now almost solely used to denote that enumeration of the people made at intervals in most European countries, and in Britain decennially. The term had its origin in Rome, where a group of the many functions performed by the high officer called censor received the name of *census*. An enumeration of the people was only one of them, but they were chiefly of a statistical character. They were especially directed to fiscal objects; and it does not appear that the enumeration of the people was then deemed of value as a source of statistical knowledge which might influence morals and legislation. It was connected with the Servian constitution, which apportioned the rights and duties of citizens to the amount of property, dividing them into six classes, which were subdivided into centuries by a mixed ratio of wealth and numbers. Had the enumeration been deemed of value for any such other purposes besides the adjustment of rights and obligations, as those for which statistical knowledge is now deemed so valuable, the notices preserved of the vast collection of statistical facts thus made would have been less scanty and meagre, and we would not have found it so impracticable to come to any conclusion about the population and extent of the city of Rome itself. The Roman census must have been minute and full. It indicated not only the number and respective classes of all free persons, but their domestic position as husbands and wives, fathers and mothers, and sons and daughters. The slaves and freedmen were indicated in connection with the possessions of the head of the house, and landed property was analyzed into several classes according to its character and produce. The important practical effect of the census caused it to be conducted at intervals generally so frequent as every fifth year. It was followed by a sacrifice of purification or lustration, whence the term of five years came to be denoted a lustrum. There were highly penal consequences to the citizen who neglected his registration for the census, to whom as an unregistered person the name of *incensus* was given. From the mixed functions to which it was applied, we have the word used among the Romans to signify the patrimony or property qualification of a particular grade—as census senatorius and census equester; and we have it employed in later times to indicate taxation. Hence *census dominicatus*, implying a feudal tax to the superior; *census duplicatus*, a double tax or feudal casualty; and the word *cense* used by old English writers was abbreviated in modern use into *cess*.

While the word census was thus applied to the taxation of the middle ages, it will readily be understood that in its modern sense it received no practical application, since neither taxation nor the adjustment of social rank required a numbering of the people; and the statistic or economic ends of such a process were as little known as they had been to the Romans. Under the despotic governments of the Continent, however, the tendency to central organization for purposes of administration and police, prepared the way for statistical inquiries into the numbers of the inhabitants of particular areas whenever there should occur an occasion for enumerating them. It was in Britain, with its abstinent government and unrestrained people, that the want of population statistics became most flagrantly conspicuous. It is difficult at present to realize the idea that, long after Adam Smith's day the number of the inhabitants of the British empire could only be guessed at as the populousness of China is at the present day; and, as in all matters of statistics, which have their own simple solution through specific inquiry, the guesses about the population of the empire were not only vague but extravagantly contradictory. During the eighteenth century, the most trustworthy geographers were generally those who did not venture on an estimate of the population even in those European states which had the best means of enumeration at their command.

The first effort to take a census of the population of Great Britain was made in 1801; it did not then extend to Ireland. The success which attended this and the two succeeding efforts was mainly owing to the zeal and ability of Mr Rickman, the assistant-clerk of the House of Commons. Where there is an organization like that of many in the European states for preserving a constant official record of all the fluctuations of the population, not only in their absolute numbers throughout a whole territory but in the relative numbers in its respective parts as they may be affected by fluctuations, systematic arrangements are thus prepared not only for obtaining a general census at any one moment, but for checking its accuracy and classifying its elements. But to deal at once with the raw material in the self-governed British empire, required great ingenuity and sagacity. A census, to be accurate, must be taken on a uniform system, and must be taken simultaneously. Any enumeration going over a tract of time, were it but two days, must be more or less inaccurate, and destitute of the means of correcting its own inaccuracies. Besides the mere abstract numbers of the people, there is much collateral information to be recorded. This, besides its own intrinsic value, is necessary as a check on the numbers; since a distribution into elements according to sex, age, social condition, occupation, and the like, affords a self-acting control on the accuracy of mere figures. In a census, indeed, it is a simple rule, that the information returned should be ramified as far beyond the main facts as with safety to these it can be carried. The tendency towards complexity in the nature of the returns must always be checked by the liability of the people at large to make blunders and create confusion where they are required to attest facts not of the most obvious nature, and by the difficulty of getting a number of subordinate officers to understand and carry out a complex classification. Hence there

has been great difficulty in obtaining a classification according to occupation, from its complex intermixture with the classification according to families. Thus, even in the first census, there was an attempt to classify the people under three divisions—(1.) Persons chiefly employed in agriculture; (2.) Persons chiefly employed in trade, manufactures, or handicraft; and (3.) All other persons not comprised in the two preceding classes. But Mr Rickman found the returns unsatisfactory, from the difficulty of deciding "whether the females of the family, children and servants, were to be classed as of no occupation, or of the occupation of the adult males of the family." In the two subsequent enumerations, the rule adopted was to record the occupation of the head of the family; but here comes a new element of confusion, in the difficulty of defining the head of a family. Experience, and an anxious desire to accomplish simplicity and comprehensiveness in the returns, were the only means by which such difficulties could be mitigated.

The enumerations of 1841 and 1851 in England were much facilitated by the uniform system of registration of births, marriages, and deaths, established in 1836, which not only afforded the means of checking the accuracy of the returns, but provided a prompt and skilled machinery accustomed to statistical work. Far more dependence could now be placed on the discretion and skill of the officers to whom the local duties were committed; and the returns were made more minute and complete. Scotland and Ireland are perhaps the only considerable countries in Christian Europe where there is no uniform system of registration. In Scotland it was necessary to adopt the clumsy method of employing the parish schoolmasters to perform the local duty in the country districts. In Ireland the first attempt at a general census was made in 1811, but it was decidedly unsuccessful. It was repeated in 1821, but went no further than a bare enumeration, of doubtful accuracy. The census there taken in 1831 was subject to correction in 1834, to make it the basis of the new system of national education. In the two subsequent enumerations the aid of the admirable constabulary force, and the use of an ordnance survey, nearly complete in 1841, have gone far to supply the want of permanent local statistical machinery.

The census of 1851 was taken on the 31st day of March, the previously distributed schedules being then collected. They embraced a return of the local and other conditions of the population during the preceding night. "At the present census," say the commissioners, "it was resolved to exhibit, not merely the statistics, as before, of parishes, and more completely of parliamentary and municipal boroughs, but also of such other large towns in England and Scotland as appeared sufficiently important for separate mention, and of all the ecclesiastical districts and new ecclesiastical parishes which, under the provision of various acts of parliament, have, during the last forty years, been created in England and Wales. In additon also to the inquiry concerning the occupation, age, and birth-place of the population, it was determined to ascertain the various relationships (such as husband, wife, son, daughter), the civil condition (as married, unmarried, widower, or widow), and the number of persons blind, deaf, and dumb." The relation of our large towns to parochial divisions has always been felt as a statistical want, but it may be questioned if it has been quite accurately supplied; and at least one important blunder has occurred in reference to Glasgow.

Another novel feature in the census of 1851 was an attempt to supply the statistics of the ecclesiastical and educational condition of the country. It stated the amount of church accommodation at the command of each religious denomination; while a return was procured of those in attendance in the several churches on Sunday 30th March. The attendance throughout thirty-five religious communities in England on that forenoon was returned as 4,428,338, of which the proportion assigned to the Establishment was 2,371,732. The returns for Scotland, admittedly very imperfect, give a total of 943,951, of which 351,454 belonged to the Establishment. These results are mentioned as characteristics of this novel feature in the periodical enumerations,—they were accompanied by many others of a startling and interesting character, on which the present is no fit occasion for enlarging. The English report was accompanied by an elaborate history of the several religious communities, valuable certainly in itself, though a questionable service to be performed by officers whose duties are purely statistical.

The two later enumerations in Ireland exhibit statistical novelties of a totally different kind. In 1841 it was resolved, as that country so totally depended on the amount of its agricultural produce, to obtain the statistics of its rural economy. The surface of the country was divided under five heads—arable, plantations, uncultivated, towns, and water; and, with a view to these divisions, a return was made of the character of each farm or other agricultural allotment, with the quantity of live stock, and other relevant facts. The attempt was found so successful, that it was renewed on the same principle, and with more full effect in 1851, producing 727 tabular folio pages of very valuable information.

For the results of census enumerations, and their connection with statistics, reference must be made to the different geographical heads, and to the articles POPULATION and STATISTICS. (J. H. B.)

CENT, a contraction of the Latin *centum*, a hundred, is used in commerce to denote a certain rate by the hundred: thus ten per cent. profit or ten per cent. loss upon the sale of any merchandise, implies that the seller has gained or lost L.10 on every L.100 of the price at which he bought that merchandise. The rate is termed *percentage.*

Cent is also the name of a copper coin of the United States of America; equal to the hundredth part of a dollar, or rather more than a halfpenny.

CENTALLO, a town of Piedmont, Sardinia, near the right bank of the Grana, province, and 7 miles N.N.E. of Coni. Pop. 5000. It was formerly of considerable importance, and its ancient castle was the residence of the Marquis of Susa.

CENTAUR, in *Astronomy*, a part of a southern constellation, in form half man and half horse; usually joined with the Wolf. See ASTRONOMY.

CENTAURI, CENTAURS, a wild race of shepherds and herdsmen inhabiting Mount Pelion in Thessaly, and who were represented in ancient fable as beings of a double form—the upper part human and the lower part that of a horse. They were the reputed offspring of Centaurus, son of Apollo, and the mares of Magnesia; or of Ixion and a cloud in the shape of Juno. The accounts of their origin are different. It is related by Palæphatus, in his *Book of Wonders*, that in the time of the Thessalian king Ixion the adjacent country was devastated by a herd of wild bulls; and that a large reward having been offered for their destruction, some young men, mounted on horses they had trained for the purpose, pursued and slew the bulls—and hence received the appellation of *Centauri, i.e. bull-killers.*

The bull-chase was a national sport among the Thes salians; and it is not improbable that their dexterity in horsemanship may have given rise to the fable of monsters half men and half horses: or perhaps it may be ascribed to the ignorance of those who, on first beholding a man mounted on horseback, supposed (as the American Indians on a like occasion) that the horse and his rider were one animal.

The battle of the Centaurs with their neighbours the Lapithæ is celebrated in ancient story. This quarrel arose at the marriage of Hippodamia with Pirithous; on which

occasion the Centaurs, flushed with wine, offered gross indignities to the assembled company. They were severely chastised for their insolence by Hercules, Theseus, and the other Lapithæ, and compelled to take refuge in Arcadia. Here they were defeated a second time by Hercules, and almost extirpated. The most famous of the Centaurs was Chiron, the friend and preceptor of Hercules, and who was accidentally slain by that hero.

CENTENARIUS, in the middle ages, an officer who had the government and administration of justice in a village. We find them among the Franks, Germans, Lombards, Goths, and other nations. Centenarius also denoted a centurion or officer who had the command of 100 men.

CENTESIMÆ USURÆ, in ancient Rome, a rate of interest which in a hundred months became equal to the principal, that is, where the money was laid out at one per cent. per month, answering to twelve per cent. per annum. The Romans reckoned their interest not by the year but by the month.

CENTESIMATION, a kind of military punishment for mutiny and the like, milder than decimation, but one man in every hundred being selected for punishment.

CENTIGRADE THERMOMETER. See BAROMETER, vol. iv. p. 457.

CENTILOQUIUM, a collection of a hundred sentences, opinions, or sayings. The centiloquium of Hermes contains a hundred aphorisms, or astrological sentences, supposed to have been written by some Arab, and falsely ascribed to Hermes Trismegistus. The famous centiloquium of Ptolemy consists likewise of a hundred sentences or doctrines, divided into short aphorisms, entitled also in Greek *καρπος*, as being the fruit or result of the former writings of that celebrated astronomer, namely his *Quadripartitum* and *Almagestum;* or rather because the use of astrological calculations is therein explained.

CENTLIVRE, SUSANNA (1667–1723), a dramatic writer, was the daughter of Mr Freeman of Holbeach, in Lincolnshire; and exhibited such an early turn for poetry, that she is said to have written a song when only seven years old. On the death of her father she was committed to the care of a stepmother, from whose treatment she determined to flee to London, where, after some equivocal adventures, she was married to a nephew of Sir Stephen Fox. About twelve months afterwards her husband died; and she was then married to an officer in the army of the name of Carrol. Carrol was killed in a duel about a year and a half after their marriage; and his widow was left to support herself by her pen. Under the name of Carrol some of her earlier pieces were published. Her first attempt was a tragic piece called the *Perjured Husband;* but her natural vivacity inclining her rather to comedy, we find but one more attempt of this kind among eighteen dramatic pieces which she afterwards wrote. In 1706 she married Mr Joseph Centlivre, principal cook to her Majesty, with whom she lived till her death in 1723. Mrs Centlivre for many years enjoyed the intimacy of Sir Richard Steele, Rowe, Budgell, Farquhar, Dr Sewell, and other persons of note, and received numerous tokens of esteem and patronage from the great. Her dramatic works were published in 3 vols. 12mo, 1761.

CENTO (Latin *cento*, patch-work), a composition formed of verses or passages from other authors, disposed in a new order.

CENTO, a town of the Papal States, 16 miles north by west of Bologna, situated in a fertile plain near the Reno. Pop. 4572. It is chiefly remarkable as the birthplace of the painter Guercino, whose house is still preserved.

CENTORBI, the ancient *Centuripo*, a town of Sicily, on a rugged mountain, province and 20 miles W.N.W. of Catania. Pop. 4500. Near it are ruins of the ancient city.

CENTRAL AMERICA. See AMERICA, GUATEMALA, &c.

CENTRAL FORCES, the powers which cause a moving body to tend towards, or recede from, the centre of motion.

CENTRE.

CENTRE, or CENTER, a word borrowed from the French name *ceintre* or *cintre*, given to the frame of timber by which the brick or stone of arched vaulting is supported during its erection, and from which it receives its form and curvature.

It is not our intention to describe the variety of constructions which may be adopted in easy situations, where the arches are of small extent, and where sufficient foundation can be had in every part of it for supporting the frame. In such cases the frequency of the props which we can set up dispenses with much care; and a frame of very slight timbers, connected together in an ordinary way, will suffice for carrying the weight, and for keeping it in exact shape. But when the arches have a wide span, and consequently a very great weight, and when we cannot set up intermediate pillars, either for want of a foundation in the soft bottom of a river, or because the arch is turned between two lofty piers, as in the dome of a stately cathedral, we are then obliged to rest every thing on the piers themselves; and the framing which is to support our arch before the keystone is set must itself be an arch, depending on the mutual abutment of its beams. One should think that this view of the construction of a centre would offer itself at the first, naturally derived from the erection it was to assist; but it has not been so. When intermediate pillars were not employed, it was usual to frame the mould for the arch with little attention to any thing but its shape, and then to cross it and recross it in all directions with other pieces of timber, till it was thought so bound together that it could be lifted in any position, and, when loaded with any weight, could not change its shape. The frame was then raised in a lump, like any solid body of the same shape, and set in its place. This is the way still practised by many country artists, who, having no clear principles to guide them, do not stop till they have made a load of timber almost equal to the weight which it is to carry.

But this artless method, besides leading the employer into great expense, is frequently fatal to the undertaker, from the unskilfulness of the construction. The beams which connect its extremities are made also to support the middle by means of posts which rest on them. They are therefore exposed to a transverse or cross strain, which they are not able to bear. Their number must therefore be increased, and this increases the load. Some of these cross strains are derived from beams which are pressed very obliquely, and therefore exert a prodigious thrust on their supports. The beams are also greatly weakened by the mortises which are cut in them to receive the tenons of the crossing beams; and thus the whole is exceedingly weak, in proportion to what the same quantity of timber may be made by a proper disposition of its parts.

General principles of construction.

The principles from which we are to derive this disposition are the general mechanical principles of carpentry, of which an account has already been given under the proper head. See CARPENTRY. These furnish one general rule. When we would give the utmost strength possible to a frame of carpentry, every piece should be so disposed that it is subject to no strain but what either pushes or draws it in the direction of its length; and, if we

would be indebted to timber alone for the force or strength of the centre, we must rest all on the first of these strains; for when the straining force tends to *draw* a beam out of its place, it must be held there by a mortise and tenon, which possesses but a very trifling force, or by iron straps and bolts. Cases occur where it may be very difficult to make every strain a thrust, and the best artists admit of ties; and indeed where we can admit a tie-beam connecting the two feet of our frame, we need seek no better security. But this may sometimes be very inconvenient. When it is the arch of a bridge that we are to support, such a tie-beam would totally stop the passage of small craft up and down the river. It would often be in the water, and thus exposed to the most fatal accidents by freshes, &c. Interrupted ties, therefore, must be employed, whose joint or meetings must be supported by something analogous to the king-posts of roofs. When this is judiciously done, the security is abundantly good. But great judgment is necessary, and a very scrupulous attention to the disposition of the pieces. It is by no means an easy matter to discern whether a beam, which makes a part of our centre, is in a state of compression or in a state of extension. In some works of the most eminent carpenters even of this day, we see pieces considered as struts, and considerable dependence had on them in this capacity, while they are certainly performing the office of tie-beams, and should be secured accordingly. This was the case in the boldest centre, we think, that has been executed in Europe, that of the bridge of Orleans, by M. Hupeau. Yet it is evidently of great consequence not to be mistaken in this point; for when we are mistaken, and the piece is stretched which we imagine to be compressed, we not only are deprived of some support that we expected, but the expected support has become an additional load.

How to distinguish a strut from a tie.

To ascertain this point, we may suppose the piers to yield a little to the pressure of the arch-stones on the centre frames. The feet, therefore, fly outwards, and the shape is altered by the sinking of the crown. We must draw our frame anew for this new state of things, and must notice what pieces must be made longer than before. All such pieces have been acting the part of tie-beams.

But a centre has still another office to sustain; it must keep the arch in its form; that is, while the load on the centre is continually increasing as the masons lay on more courses of arch-stones, the frame must not yield and go out of shape, sinking under the weight on the haunches, and rising in the crown, which is not yet carrying any load. The frame must not be supple, and must derive its stiffness, not from the closeness and strength of its joints, which are quite insignificant when set in competition with such immense strains, but from struts or ties, properly disposed, which hinder any of the angles from changing its amplitude.

How to secure stiffness and strength.

It is obvious, from all that has been said, that the strength and stiffness of the whole must be found in the triangles into which this frame of carpentry may be resolved. We have seen that the strains which one piece produces on two others with which it meets in one point, depend on the angles of their intersection; and that it is greater as an obtuse angle is more obtuse, or an acute angle more acute. And this suggests to us the general maxim, "to avoid as much as possible all very obtuse angles." Acute angles, which are not necessarily accompanied by obtuse ones, are not so hurtful, because the strain here can never exceed the straining force; whereas, in the case of an obtuse angle, it may surpass it in any degree.

Such are the general rules on this subject. Although something of the mutual abutment of timbers, and the support derived from it, has been long perceived, and employed by the carpenters in roofing, and also, doubtless, in the forming of centres, yet it is a matter of historical fact, that no general and distinct views had been taken of it till about the beginning of last century, or a little earlier. Fontana has preserved the figure of the frames on which the arches of St Peter's at Rome were turned. The one employed for the dome is constructed with very little skill; and those for the arches of the nave and transepts, though incomparably superior, and of considerable simplicity and strength, are yet far inferior to others which have been employed in later times. It is much to be regretted that no trace remains of the forms employed by the great architect and consummate mechanician Sir Christopher Wren. We should doubtless have seen in them every thing that science and great sagacity could suggest. We are told, indeed, that his centring for the dome of St Paul's was a wonder of its kind; begun in the air at the height of 160 feet from the ground, and without making use of even a projecting cornice whereon to rest.

The earliest theory on scientific principles.

The earliest theory of the kind that we have met with, that is proposed on scientific principles, and with the express purpose of serving as a lesson, are two centres by M. Pitot of the Academy of Sciences, about the beginning of last century. As they have considerable merit, greatly resembling those employed by Michael Angelo in the nave of St Peter's, and afford some good maxims, we shall give a short account of them. We crave the excuse of the artists if we should employ their terms of art somewhat awkwardly, not being very familiarly acquainted with them. Indeed, we observe very great differences, and even ambiguity, in the terms employed.

What we shall describe under the name of a *centre* is, properly speaking, only one frame, truss, or rib, of a centre. They are set up in vertical planes, parallel to each other, at the distance of five, six, seven, or eight feet, like the trusses or main couples of a roof. Bridging joists are laid across them. In smaller works these are laid sparingly, but of considerable scantling, and are boarded over; but for great arches, a bridging joist is laid for every course of arch-stones, with blockings between to keep them at their proper distances. The stones are not laid immediately on these joists, but beams of soft wood are laid along each joist, on which the stone is laid. These beams are afterwards cut out with the chisel, in order to separate the centre from the ring of stones, which must now support each other by their mutual abutment.

Illustrated Pl. CLXV

The centre is distinguishable into two parts, ALLB (fig. 1) and LDL, which are pretty independent of each other, or at least act separately. The horizontal stretcher LL cuts the semicircle ADB half way between the spring and the crown of the arch; the arches AL, LD, being 45° each. This stretcher is divided in the same proportion in the points G and H; that is, GH is one half of LL, and LG, HL, are each one fourth of LL nearly. Each end is supported by two struts EI, GI, which rest below on a sole or bed properly supported. The interval between the heads of the struts GI, HK, is filled up by the straining beam GH, abutting in a proper manner on the struts (see Carpentry). The extremities L, L, are united in like manner by butting joints, with the heads of the outer struts. The arch moulds AP, BP, are connected with the struts by cross pieces PQ, which we shall call bridles, which come inwards on each side of the struts, being double, and are bolted to them. This may be called the lower part of the frame. The upper part consists of the king-post DR, supported on each side by the two struts or braces ML, ON, mortised into the post, and also mortised into the stretcher, at the points L, N, where it is supported by the struts below. The arches LD, LD, are connect-

ed with the struts by the bridles PQ, in the same manner as below.

Propriety of this arrangement.

There is a great propriety in many parts of this arrangement. The lower parts or haunches of the arch press very lightly on the centres. Each arch-stone is lying on an inclined plane, and tends to slide down only with its relative weight; that is, its weight is to its tendency to slide down the joint as radius to the sine of elevation of the joint. Now it is only by this tendency to slide down the joint that they press on the centring, which in every part of the arch is perpendicular to the joint: but the pressure on the joint arising from this cause is much less than this, by reason of the friction of the joints. A block of dry freestone will not slide down at all, and therefore will not press on the centring, if the joint be not elevated thirty-five degrees at least. But the arch-stones are not laid in this manner, by sliding them down along the joint, but are laid on the centres, and slide down *their* slope, till they touch the blocks on which they are to rest; so that, in laying the arch-stones, we are by no means allowed to make the great deduction from their weight just now mentioned, and which M. Couplet prescribes (*Mém. Acad. Sciences*, 1729.) But there is another cause which diminishes the pressure on the centres: each block slides down the planks on which it is laid, and presses on the block below it, in the direction of the tangent to the arch. This pressure is transmitted through this block, in the same direction, to the next, and through it to the third, &c. In this manner it is plain that, as the arch advances, there is a tangential pressure on the lower arch-stones, which diminishes their pressure on the frame, and, if sufficiently great, might even push them away from it. M. Couplet has given an analysis of this pressure, and shows, that in a semicircular arch of uniform thickness none of the arch-stones below thirty degrees press on the frames. But he, without saying so, calculates on the supposition that the blocks descend along the circumference of this frame in the same manner as if it were perfectly smooth. As this is far from being the case, and as the obstructions are to the last degree various and irregular, it is quite useless to institute any calculation on the subject. A little reflection will convince the reader, that in this case the obstruction arising from friction *must* be taken into account, and that it *must not* be taken into account in estimating the pressure of each successive course of stones as they are laid. It is enough that we see that the pressure of the lower courses of arch-stones on the frame is diminished. M. Couplet says, that the whole pressure of a semicircular arch is but four ninths of its weight; but it is much greater, for the reason just now given. We have tried, with a well-made wooden model (of which the circumference was rubbed with black lead, to render it more slippery) whether *any* part of the wooden blocks representing the arch-stones were detached from the frame by the tangential pressure of the superior blocks; but we could not say confidently that any were so detached. We perceived that all kept hold of a thin slip of Chinese paper (also rubbed with black lead) between them and the frame, so that a sensible force was required to pull it out. From a combination of circumstances, which it would be tedious to relate, we believe that the centres carry more than two thirds of the weight of the arch before the keystone is set. In elliptical and lower pitched circular arches, the proportion is still greater.

By a centre of M. Pitot's.

It seems reasonable enough, therefore, to dispose the framing in the manner proposed by Pitot, directing the main support to the upper mass of the arch, which presses most on the frame. We shall derive another advantage from this construction, which has not occurred to M. Pitot.

There is an evident propriety in the manner in which he has distributed the supports of the upper part. The struts which carry the king-post spring from those points of the stretcher where it rests on the struts below. Thus the stretcher, on which all depends, bears no transverse strains. It is stretched by the strut above it, and it is compressed in a small degree between the struts below it, at least by the outer ones. M. Pitot proposes the straining beam GH as a lateral support to the stretcher, which may therefore be of two pieces; but although it *does* augment its strength, it does not seem necessary for it. The stretcher is abundantly carried by the strap, which may and should suspend it from the king-post. The great use of the straining piece is to give a firm abutment to the inner struts, without allowing any lateral strain on the stretcher.—*N. B.* Great care must be taken to make the hold sufficiently firm and extensive between the stretcher and the upper struts, so that its cohesion to resist the thrusts from these struts may be much employed.

The only imperfection that we find in this frame is the lateral strains which are brought upon the upper struts by the bridles, which certainly transmit to them part of the weight of the arch-stones on the curves. The space between the curves and ML should also have been trussed. M. Pitot's form is, however, extremely stiff; and the causing of the middle bridle to reach down to the stretcher seems to secure the upper struts from all risk of bending.

This centre gives a very distinct view of the offices of all the parts, and makes therefore a proper introduction to the general subject. It is the simplest that can be in its principle, because all the essential parts are subjected to one kind of strain. The stretcher LL is the only exception, and its extension is rather a collateral circumstance than a step in the general support.

Strength of this frame

The examination of the strength of the frame is extremely easy. M. Pitot gives it for an arch of sixty feet span, and supposes the arch-stones seven feet long, which is a monstrous thickness for so small an arch; four feet is an abundant allowance; but we shall abide by his construction. He gives the following scantlings of the parts:—

The ring or circumference consists of pieces of oak twelve inches broad and six thick.

The stretcher LL is twelve inches square.

The straining piece GH is also twelve by twelve.

The lower struts ten by eight.

The king-post twelve by twelve.

The upper struts ten by six.

The bridles twenty by eight.

These dimensions are French, which is about one seventeenth larger than ours, and the superficial dimensions (by which the section and the absolute strength is measured) are almost one eighth larger than ours. The cubic foot, by which the stones are measured, exceeds ours by nearly one fifth. The pound is deficient about one thirteenth. But since very nice calculation is neither easy nor necessary on this subject, it is needless to depart from the French measures, which would occasion many fractional parts, and a troublesome reduction.

The arch is supposed to be built of stone which weighed a hundred and sixty pounds per foot. M. Pitot, by a computation, in which he has committed a mistake, says, that only eleven fourteenths of this weight is carried by the frame. We believe, however, that this is nearer the truth than M. Couplet's assumption of four ninths, already mentioned.

M. Pitot further assumes, that a square inch of sound oak will carry 8640 pounds. By his language we should imagine that it will not carry much more; but this is very far below the strength of any British oak that we have tried; so far, indeed, that we rather imagine that he means

Centre. that this load may be laid on it with perfect security for any time. But to compensate for knots and other accidental imperfections, he assumes 7200 as the measure of its absolute force.

He computes the load on each frame to be 707,520 pounds, which he reduces to $\frac{11}{14}$ths, or 555,908 pounds.

The absolute force of each of the lower struts is 576,000 (at 7200 per inch), and that of the curves 518,400. M. Pitot, considering that the curves are kept from bending outwards by the arch-stones which press on them, thinks that they may be considered as acting precisely as the outer struts EI. We have no objection to this supposition.

computed. With these data we may compute the load which the lower truss can safely bear, by the rule delivered in the article Carpentry. We therefore proceed as follows:

Measure off by a scale of equal parts as, at, each 576,000, and add tv 518,400. Complete the parallelogram $avxs$, and draw the vertical xc, meeting the horizontal line aC in c. Make cb equal to ca. Join xb, and complete the parallelogram $axby$. It is evident that the diagonal xy will represent the load which these pieces can carry; for the line av is the united force of the curve AP and the strut IE, and as is the strength of IG. These two are equivalent to ax. xb is, in like manner, equivalent to the support on the other side, and xy is the load which will just balance the two supports ax and bx.

When xy is measured on the same scale, it will be found =2,850,000 pounds. This is more than five times the load which actually lies on the frame. It is therefore vastly stronger than is necessary. Half of each of the linear dimensions would have been quite sufficient, and the struts needed only to be five inches by four. Even this would have carried twice the weight, and would have borne the load really laid on it with perfect safety.

We proceed to measure the strength of the upper part. The force of each strut is 432,000, and that of the curve is 518,400; therefore, having drawn Mv parallel to the strut ON, make Mv = 432,000, and Ms = 432,000 + 518,400. Complete the parallelogram Msrv. Draw the horizontal line rk, cutting the vertical MC in k, and make ky = Mk. It is plain, from what was done for the lower part, that My will measure the load which can be carried by the upper part. This will be found =1,160,000. This is also greatly superior to the load, but not in so great a proportion as the other part. The chief part of the load lies on the upper part, but the chief reason of the difference is the greater obliquity of the upper struts. This shortens the diagonal My of the parallelogram of forces. M. Pitot should have adverted to this, and instead of making the upper struts more slender than the lower, he should have made them stouter.

The strain on the stretcher LL is not calculated. It is measured by rk, when My is the load actually lying on the upper part. Less than the sixth part of the cohesion of the stretcher is more than sufficient for the horizontal thrust, and there is no difficulty in making the foot joints of the struts abundantly strong for the purpose.

The reader will perceive that the computation just now given does not state the proportions of the strains *actually exerted* on the different pieces, but the load on the whole, on the supposition that each piece is subjected to a strain proportioned to its strength. The other calculation is much more complicated, but is not necessary here.

This centre has a very palpable defect. If the piers should yield to the load, and the feet of the centre fly out, the lower part will exert a very considerable strain on the stretcher, tending to break it across between N and L, and on the other side. HKF of the lower part is firmly bound together, and cannot change its shape, and will therefore act like a lever, turning round the point F. It will draw the strut HK away from its abutment with GH, and the stretcher will be strained across at the place between H and F, where it is bolted with the bridle. This may be resisted in some degree by an iron strap uniting ON and HK, but there will still be a want of proportional strength. Indeed, in an arch of such height, a semicircle, there is but little risk of this yielding of the piers, but it is an imperfection. Centre.

A centre on the same principles for an elliptical arch. The centre (fig. 2, No. 1) is constructed on the same principle precisely for an elliptical arch.[1] The calculation of its strength is nearly the same also; only the two upper struts of a side being parallel, the parallelogram Msrv (of fig. 1) is not needed, and in its stead we measure off on ON a line to represent twice its strength. This comes in place of Mr of fig. 1.—*N. B.* The calculation proceeds on the supposition that the short straining piece MM makes but one firm body with the king-post. Mr Pitot employed this piece, we presume, to separate the heads of the struts, that their obliquity might be lessened thereby; and this is a good thought, for when the angle formed by the struts on each side is very open, the strain on them becomes very great.

The stretcher of this frame is scarfed in the middle. Suppose this joint to yield a little, there is a danger of the lower strut ON losing its hold, and ceasing to join in the support; for when the crown sinks by the lengthening of the stretcher, the triangle ORN of fig. 2 will be more distorted than the space above it, and ON will be loosened. But this will not be the case when the sinking of the crown arises from the mere compression of the struts. Nor will it happen at all in the centre, fig. 1. On the contrary, the strut ON will abut more firmly by the yielding of the foot of ML.

The figure of this arch of M. Pitot's consists of three arches of circles, each of 60 degrees. As it is elegant, it will not be unacceptable to the artist to have a construction for this purpose.

How to construct such an arch. Make BY = CD, and CZ′ = $\frac{1}{2}$ CY. Describe the semicircle ZÆY, and make ZS′ = ZÆ. S is the centre of the side arches, each of 60 degrees. The centre T of the arch, which unites these two, is at the angle of an equilateral triangle STS′.

This construction of M. Pitot's makes a handsome oval, and very nearly an ellipsis, but lies a little without it. We shall add another of our own, which coincides with the ellipse in eight points, and furnishes the artist, by the way, with a rule for drawing an infinite variety of ovals.

Let AB, DE (fig. 2, No. 2), be the axes of an ellipse, C the centre, and F f the two foci. Make C b = CD, and describe a circle AD b e passing through the three given points A, D, and b. It may be demonstrated, that if from any point P of the arch AD be drawn a cord PD, and if a line PR r be drawn, making the angle DPR = PDC, and meeting the two axes in the points R and r, then R and r will be the centres of circles, which will form a quarter APD of an oval, which has AB and DE for its two axes.

We want an oval which shall coincide as much as possible with an ellipsis. The most likely method for this is to find the very point P where the ellipsis cuts the circle AD b e. The easiest way for the artist is to describe an arch of a circle a m, having AB for its radius, and the remote focus f for its centre. Then set one foot of the com-

[1] It is the middle arch of the bridge at L'Ile Adam, of which M. Pitot had the direction. It is of eighty feet span, and rises thirty-one feet.

passes on any point P, and try whether the distance PF from the nearest focus F is exactly equal to its distance P m from that circle. Shifting the foot of the compasses from one point of the arch to another will soon discover the point. This being found, draw PD, make the angle DP r = PD r, and R and r are the centres wanted. Then make CS = CR, and we get the centres for the other side.

The geometer will not relish this mechanical construction. He may therefore proceed as follows: "Draw ed the diameter of the circle, cutting AB in N; join Dd, and produce it so that dH may be equal to CD, and join eH, meeting AB in Q. On B and Q, as centres with any radius, describe arcs cutting each other in X, and on C and N with the same radius describe arcs cutting each other in Y. Take the distance XN in the compasses, and on Y as a centre describe an arc cutting AB in M and M′, and draw MP, M′P′ perpendicular to AB. These ordinates will cut the circle in the points P and P, where it is cut by the ellipse."[1] We leave the demonstration as an exercise for the *dilettante*.

Centre for the nave of St Peter's.

We said that this centring of M. Pitot's resembled in principle the one employed by Michael Angelo for the nave and transepts of St Peter's church at Rome. Fontana, who has preserved this, ascribes the construction of it to one of the name of San Gallo. A sketch of it is given in fig. 3. It is, however, so much superior, and so different in principle, from that employed for the cupola, that we cannot think it the invention of the same person. It is, like Pitot's, not only divisible, but really divided into two parts, of which the upper carries by much the greatest part of the load. The pieces are judiciously disposed, and every important beam is amply secured against all transverse strains. Its only fault is a great profusion of strength. The innermost polygon $aghb$ is quite superfluous, because no strain can force in the struts which rest on the angles. Should the piers yield outwards, this polygon will be loose, and can do no service. Nor is the triangle gih of any use, if the king-post above it be strapped to the tie-beam and straining sill. Perhaps the inventor considered the king-post as a pillar, and wished to secure the tie-beam against its cross strain. This centring, however, must be allowed to be very well composed; and we expect that the well-informed reader will join us in preferring it to M. Pitot's, both for simplicity of principle and scientific propriety, as well as for strength.

There is one considerable advantage which may be derived from the actual division of the truss into two parts. If the tie-beam LL, instead of resting on the stretcher EF, had rested on a row of chocks formed like double wedges, placed above each other head to point, the upper part of the centring might be struck independent of the lower, and this might be done gradually, beginning at the outer ends of the stretcher. By this procedure the joints of the arch-stones will close on the haunches, and will almost relieve the lower centring, so that all can be pulled out together. Thus may the arch settle and consolidate in perfect safety, without any chance of breaking the bond of the mortar in any part; an accident which frequently happens in great arches. This procedure is peculiarly advisable for low pitched or elliptical arches. But this will be more clearly seen afterwards, when we treat of the internal movements of an arch of masonry.

This may suffice for an account of the more simple construction of trussed centres; and we proceed to such as have a much greater complication of principle. We shall take for examples some constructed by M. Perronet, a very celebrated French architect.

Perronet's maxim of construction.

M. Perronet's general maxim of construction is to make the truss consist of several courses of separate trusses, independent, as he thinks, of each other, and thus to employ the joint support of them all. In this construction it is not intended to make use of one truss, or part of one truss, to support another, as in the former set, and as is practised in the roofs of St Paul's church, Covent Garden, and in Drury Lane theatre. Each truss spans over the whole distance of the piers, and would stand alone (having, however, a tottering equilibrium). It consists of a number of struts, set end to end, and forming a polygon. These trusses are so arranged that the angles of one are in the middle of the sides of the next, as when a polygon is inscribed in a circle, and another (of the same number of sides) is circumscribed by lines which touch the circle in the angles of the inscribed polygon. By this construction the angles of the alternate trusses lie in lines pointing towards the centre of the curve. King-posts are therefore placed in this direction, between the adjoining beams of the trusses. These king-posts consist of two beams, one on each side of the truss, and embrace the truss-beams between them, meeting in the middle of their thickness. The abutting beams are mortised, half into each half of the post. The other beam, which makes the base of the triangle, passes through the post, and a strong bolt is driven through the joint, and secured by a key or a nut. In this manner is the whole united; and it is expected, that when the load is laid on the uppermost truss, it will all butt together, forcing down the king-posts, and therefore pressing them on the beams of all the inferior trusses, causing them also to abut on each other, and thus bear a share of the load. M. Perronet does not assume the invention to himself, but says that it was invented and practised by M. Mansard de Sagonne at the great bridge of Moulins. It is much more ancient, and is the work of the celebrated physician and architect Perrault, as may be seen in the collection of machines and inventions of that gentleman, published after his death, and also in the great collection of inventions approved of by the Academy of Sciences. It is this which we propose to examine.

Centring employed for the bridge of Cravant.

Fig. 4 represents the centring employed for the bridge of Cravant. The arches are elliptical, of sixty feet span and twenty feet rise. The arch-stones are four feet thick, and weigh 176 pounds per foot. The truss-beams were from fifteen to eighteen feet long, and their section was nine inches by eight. Each half of the king-posts was about seven feet long, and its section nine inches by eight. The whole was of oak. The five trusses were five and a half feet asunder. The whole weight of the arch was 1,350,000 lbs., which we may call 600 tons (it is 558). This is about 112 tons for each truss. We must allow nearly ninety tons of this really to press the truss. A great part of this pressure is borne by the four beams which make the feet of the truss, coupled in pairs on each side. The diagonal of the parallelogram of forces drawn for these beams is, to one of the sides, in the proportion of 360 to 285. Therefore say, as 360 to 285, so is 90 to $71\frac{1}{4}$

---

[1] The construction given in the Supplement to the Third Edition, by the writer of this article (the late Professor Robison), is here left out, and another more simple (that marked by inverted commas) put in its stead. If we put a for the semi-transverse cA, b for the semi-conjugate cD, and denote the distance of the ordinates CM, CM′, from the centre by x, then CM and CM′ will be the roots of this quadratic equation:

$$x^2 - \frac{a-b}{a+b}ax = \frac{2a^3b}{(a+b)^2}.$$

The above construction has been derived from this equation. (E.)

Centre.

tons, the thrust on each foot. The section of each is 144 inches. We may with the utmost safety lay three tons on every inch for ever. This amounts to 432 tons, which is more than six times the strain really pressing the foot-beams in the direction of their length; nay, the upper truss alone is able to carry much more than its load. The absolute strength of its foot-beam is 216 tons. It is much more advantageously placed, for the diagonal of the parallelogram of forces corresponding to its position is to the side as 438 to 285. This gives $58\frac{6}{10}$th tons for the strain on each foot, which is not much above the fourth part of what it is able to carry for ever. No doubt can therefore be entertained of the superabundant strength of this centring. We see that the upper row of struts is quite sufficient, and all that is wanted is to procure stiffness for it; for it must be carefully kept in mind that this upper row is not like an equilibrated arch. It will be very unequally loaded as the work advances. The haunches of the frame will be pressed down, and the joints at the crown raised up. This must be resisted.

Here then we may gather by the way a useful lesson. Let the outer row of struts be appropriated to the carriage of the load, and let the rest be employed for giving stiffness. For this purpose let the outer row have abundant strength. The advantages of this method are considerable. The position of the beams of the exterior row is more advantageous when, as in this example, the whole is made to rest on a narrow foot; for this obliges us to make the last angle, at least of the lower row, more open, which increases the strain on the strut; besides, it is next to impossible to distribute the compressing thrusts among the different rows of the truss-beams; and a beam which, during one period of the mason work, is acting the part of a strut, in another period is bearing no strain but its own weight, and in another it is stretched as a tie. A third advantage is, that, in a case like this, where all rests on a narrow foot, and the lower row of beams are bearing a great part of the thrust, the horizontal thrust on the pier is very great, and may push it aside. This is the most ruinous accident that can happen. An inch or two of yielding will cause the crown of the arch to sink prodigiously, and will instantly derange all the bearings of the abutting beams; but when the lower beams already act as ties, and are quite adequate to their office, we render the frame perfectly stiff or unchangeable in its form, and take away the horizontal thrust from the piers *entirely*. This advantage is the more valuable, because the very circumstance which obliges us to rest all on a narrow foot, places this foot on the very top of the pier, and makes the horizontal thrust the more dangerous.

But, to proceed in our examination of the centring of Cravant Bridge, let us suppose that the king-posts are removed, and that the beams are joined by compass joints. If the pier shall yield in the smallest degree, both rows of struts must sink; and since the angles, at least the outermost, of the lower rows are more open than those of the upper row, the crown of the lower row will sink more than that of the upper.

The angles of the alternate rows must therefore separate a little. Now restore the king-posts, they prevent this separation. Therefore *they are stretched;* therefore the beams of the lower row are also stretched; consequently they no longer butt on their mortises, and must be held in their places by bolts. Thus it appears that, in this kind of sagging, the original distribution of the load among the different rows of beams is changed, and the upper row becomes loaded beyond our expectation.

If the sagging of the whole truss proceed only from the compression of the timbers, the case is different, and we *may* preserve the original distribution of mutual abutment more accurately. But in this case the stiffness of the frame arises chiefly from cross strains. Suppose that the frame is loaded with arch-stones on each side up to the posts HC, *hc;* the angles E and *e* are pressed down and the beams EOF, *eo* F, push up the point F. This cannot rise without bending the beams EOF, *eo* F; because O and *o* are held down by the double king-posts, which grasp the beams between them. There is therefore a cross strain on the beams. Observe also that the triangle EHF does not preserve its shape by the connection of its joints; for although the strut-beams are mortised into the king-post, they are in very shallow mortises, rather for steadying them than for holding them together. M. Perronet did not even pin them, thinking that their abutment was very great. The triangle is kept in shape by the base EF, which is firmly bolted into the middle post at O. Had these intersections not been strongly bolted, we imagine that the centres of some of M. Perronet's bridges would have yielded much more than they did; yet some of them yielded to a degree that our artists would have thought very dangerous. M. Perronet was obliged to load the crown of the centring with very great weights, increasing them as the work advanced, to prevent the frames from going out of shape; in one arch of 120 feet he laid on forty-five tons. Notwithstanding this imperfection, which is perhaps unavoidable, this mode of framing is undoubtedly very judicious, and perhaps the best which can be employed without depending on iron work.

Fig. 5 represents another, constructed by Perronet, for an arch of ninety feet span and twenty-eight feet rise. The trusses were seven feet apart, and the arch was four and a half thick; so that the unreduced load on each frame was very nearly 235 tons. The scantling of the struts was fifteen by twelve inches. The principle is the same as that of the former. The chief difference is, that in this centre the outer truss-beam of the lower row is not coupled with the middle row, but kept nearly parallel to the outer beam of the upper row. This adds greatly to the strength of the foot, and takes off much of the horizontal thrust from the pier.

For the bridge of Nogent.

M. Perronet has shown great judgment in causing the polygon of the inner row of truss-beams gradually to approach the polygon of the outer row. By this disposition, the angles of the inner polygon are more acute than those of the outer. A little attention will show that the general sagging of all the polygons will keep the abutments of the lower one nearer, or exactly, to their original quantity. We must indeed except the foot-beam. It is still too oblique; and, instead of converging to the foot of the upper row, it should have diverged from it. Had this been done, this centre is almost perfect in its kind. As it is, it is at least six times stronger than was absolutely necessary. We shall have occasion to refer to this figure on another occasion.

This maxim is better exemplified by M. Perronet in the centring of the bridge of St Maxence, exhibited in fig. 5, No. 2, than in that of Nogent, fig. 5, No. 1. But we think that a horizontal truss-beam *ab* should have been inserted, in a subordinate manner, between the king-posts next the crown on each side. This would prevent the crown from rising while the haunches only are loaded, without impairing the fine abutments of *cd, cd,* when the arch is nearly completed. This is an excellent centring, but is not likely to be of much use in these kingdoms, because the arch itself will be considered as ungraceful and ugly, looking like a huge lintel. Perronet says that he preferred it to the ellipse, because it was lighter on the piers, which were thin. But the failure of one arch must be immediately followed by the ruin of all We know much better methods of lightening the piers.

St Maxence,

Centre. Neuilly, and

Fig. 6 represents the centring of the bridge of Neuilly, near Paris, also by Perronet. The arch has 120 feet span and thirty feet rise, and is five feet thick. The frames are six feet apart, and each carries an absolute (that is, not reduced to $\frac{11}{14}$ths or to $\frac{4}{5}$ths) load of 350 tons. The strut-beams are seventeen by fourteen inches in scantling. The king-posts are fifteen by nine each half; and the horizontal bridles, which bind the different frames together in five places, are also fifteen by nine each half. There are eight other horizontal binders of nine inches square.

This is one of the most remarkable arches in the world; not altogether on account of its width, for there are several much wider, but for the flatness at the crown; for about twenty-six feet on each side of the middle it was intended to be a portion of a circle of 150 feet radius. An arch (semicircular) of 300 feet span might therefore be easily constructed, and would be much stronger than this, because its horizontal thrust at the crown would be vastly greater, and would keep it more firmly united.

The bolts of this centre are differently placed from those of the former, and the change is judicious. M. Perronet had doubtless found by this time that the stiffness of his framing depended on the transverse strength of the beams, and therefore he was careful not to weaken them by the bolts. But notwithstanding all his care, the framing sunk upwards of thirteen inches before the keystones were laid; and during the progress of the work, the crown rose and sunk, by various steps, as the loading was extended along it. When twenty courses were laid on each side, and about sixteen tons laid on the crown of each frame, it sunk about an inch. When forty-six courses were laid, and the crown loaded with fifty tons, it sunk about half an inch more. It continued sinking as the work advanced; and when the keystone was set it had sunk thirteen inches and a quarter. But this sinking was not general; on the contrary, the frame had risen greatly at the very haunches, so as to open the upper part of the joints, many of which gaped an inch; and this opening of the joints gradually extended from the haunches towards the crown, in the neighbourhood of which they opened on the under side. This evidently arose from a want of stiffness in the frame. But these joints closed again when the centres were struck, as will be mentioned afterwards.

We have taken particular notice of the movements and twisting of this centre, because we think that they indicate a deficiency, not only of stiffness, but of abutment among the truss-beams. The whole has been too flexible, because the angles are too obtuse: this arises from their multiplicity. When the intercepted arches have so little curvature, the power of the load to press it inward increases very fast. When the intercepted arch is reduced to one half, this power is more than doubled; and it is also doubled when the radius of curvature is doubled. The king-posts should have been farther apart near the crown, so that the quantity of arch between them should compensate for its diminished curvature.

The power of withstanding any given inequality of load would therefore have been greater had the centre consisted of fewer pieces, and their angles of meeting been proportionally more acute. The greatest improvement would have been to place the foot of the lower tier of truss-beams on the very foot of the pier, and to have also separated it at the head from the rest with a longer king-post, and thus to have made the distances of the beams on the king-posts increase gradually from the crown to the spring. This would have made all the angles of abutment more acute, and would have produced a greater pressure on all the lower tiers when the frames sagged.

Orleans.

Fig. 7 represents the centring of the bridge of Orleans. The arch has 100 feet span, and rises thirty, and the arch-stones are six feet long. It is the construction of M. Hupeau, the first architect of the bridge. It is the boldest work of the kind that we have seen, and is constructed on clear principles. The main abutments are few in number. Because the beams of the outer polygon are long, they are very well supported by straining beams in the middle; and the struts or braces which support and butt on them are made to rest on points carried entirely by *ties*. The inventor, however, seems to have thought that the angles of the inner polygon were supported by mutual compression, as in the outer polygon. But it is plain that the whole inner polygon may be formed of iron rods. Not but that both polygons *may* be in a state of compression; this is very possible; but the smallest sagging of the frame will change the proportions of the pressures at the angles of the two polygons. The pressures on the exterior angles will increase, and those on the lower or interior angles will diminish most rapidly; so that the abutments in the lower polygons will be next to nothing. Such points could bear very little pressure from the braces which support the middle of the long bearings of the upper beams, and their pressures must be borne chiefly by the joints supported by the king-posts. The king-posts would then be in a state of extension. It is difficult, however, to decide what is the precise state of the pressure at these interior angles.

Instructive history of the centre.

The history of the erection of this bridge will throw much light on this point, and is very instructive. M. Hupeau died before any of the arches were carried farther than a very few of the first courses. M. Perronet succeeded to the charge, and finished the bridge. As the work advanced, the crown of the frame rose very much. It was loaded; and it sunk as remarkably. This showed that the lower polygon was giving very little aid. M. Perronet then thought the frame too weak, and inserted the long beam DE, making the diagonal of the quadrangle, and very nearly in the direction of the lower beam $a\,b$, but falling rather below this line. He now found the frame abundantly strong. It is evident that the truss is now changed exceedingly, and consists of only the two long sides, and the short straining beam lying horizontally between their heads. The whole centring consists now of one great truss, $a\,\mathrm{E}\,e\,b$, and its long sides, $a\,\mathrm{E}$, $e\,b$, are trussed up at B and f. Had this simple idea been made the principle of the construction, it would have been excellent. The angle $a\,\mathrm{DE}$ might have been about 176°, and the polygon $\mathrm{D}\,c\,g\,h$ employed only for giving a slight support to this great angle, so as not to allow it to exceed 180°. But M. Perronet found that the joint c, at the foot of the post E c, was about to *draw loose*, and he was obliged to bolt long pieces of timber on each side of the joint, embracing both beams. These were evidently acting the same part as iron straps would have done; a complete proof that, whatever may have been the original pressures, there was no abutment now at the point c, and that the beams that met there were not in a state of compression, but were on the stretch. M. Perronet says that he put these cheeks to the joints *to stiffen* them. But this was not their office, because the adjoining beams were not struts, but ties, as we have now proved.

We may therefore conclude that the outer polygon, with the assistance of the pieces $a\,b$, DE, were carrying the whole load. We do not know the distance between the frames; but supposing them seven feet apart, and the arch six feet thick, and weighing 170 pounds per foot, we learn the load. The beams were sixteen inches square. If we now calculate what they would bear at the same very moderate rate allowed to the other centres, we find that the beams AB and $a\,b$ are not loaded to one sixth of their strength.

We have given this centre as a fine example of what carpentry is able to perform, and because, by its simplicity, it is a sort of text on which the intelligent artist may make many comments. We may see plainly that, if the lower polygon had been formed of iron rods, firmly bolted into the feet of the king-posts, it would have maintained its shape completely. The service done by the beam DE was not so much an increase of abutment as a discharge of the weight and of the *pull* at the joint *c*. Therefore, in cases where the feet of the truss are *necessarily* confined to a very narrow space, we should be careful to make the upper polygon sufficient to carry the whole load, say by doubling its beams, and we may then make the lower polygon of slender dimensions, provided we secure the joints on the king-posts by iron straps which embrace a considerable portion of the tie on each side of the joint.

All these centres good in their kind.

We are far from thinking that these centres are of the best kind that could be employed in their situation; but they are excellent in their kind, and a careful study of them will teach the artist much of his profession. When we have a clear conception of the state of strain in which the parts of a frame really are, we know what should be done in order to draw all the advantages possible from our materials. We have said in another place, that where we can give our joints sufficient connection, as by straps and bolts, or by cheeks or fishes, it is better to use ties than struts, because ties never bend.

We do not approve of M. Perronet's practice of giving his trusses such narrow feet. By bringing the foot of the lower polygon farther down, we greatly diminish all the strains, and throw more load on the lower polygon; and we do not see any of M. Perronet's centres where this might not have been done. He seems to affect a great span, to show the wonders of his art; but our object is to teach how to make the best centre of a given quantity of materials, and how to make the most perfect centre, when we are not limited in this respect, nor in the extent of our fixed points.

Excellence of the centre employed for Blackfriars Bridge.

We shall conclude this series of examples with one where no such affectation takes place. This is the centring of the bridge at Blackfriars, London. The span of the arch is one hundred feet, and its height from the spring is about forty-three. The drawing, fig. 8, is sufficiently minute to convey a distinct notion of the whole construction. We need not be very particular in our observations, after what has been said on the general principles of construction. The leading maxim, in the present example, seems to be, *that every part of the arch shall be supported by a simple truss of two legs, resting, one on each pier*. H, H, &c. are called apron-pieces, to strengthen the exterior joints, and to make the ring as stiff in itself as possible. From the ends of this apron-piece proceed the two legs of each truss. These legs are twelve inches square; they are not of an entire piece, but of several, meeting in firm abutment. Some of their meetings are secured by the double king-posts, which grasp them firmly between them, and are held together by bolts. At other intersections, the beams appear halved into each other, a practice which cannot but weaken them much, and would endanger their breaking by cross strains, if it were possible for the frame to change its shape. But the great breadth of this frame is an effectual stop to any such change. The fact was, that *no sinking or twisting whatever* was observed during the progress of the mason-work. Three points in a straight line were marked on purpose for this observation, and were observed every day. The arch was more than six feet thick, and yet the sinking of the crown, before setting the keystones, did not amount to one inch.

The centre employs about one third more timber than Perronet's great centre in proportion to the span of the arch; but the circumference increases in a greater proportion than this, because it is more elevated. In every way of making a comparison of the dimensions, Mr Mylne's arch employs more timber; but it is *beyond all comparison* stronger. The great elevation is partly the reason of this. But the disposition of the timbers is also much more advantageous, and may be copied even in the low pitched arches of Neuilly. The simple truss, reaching from pier to pier for the middle point of the arch, gives the strong support where it is most of all wanted; and in the lateral points H, although one leg of the truss is very oblique, the other compensates for it by its upright position.

The chief peculiarity of this centre is to be seen in its base. This demands a more particular attention; but we must first make some observations on the condition of an arch, as it rests on the centring after the keystones are all set, and on the gradual transference of the pressure from the boards of the centring to the joints of the arch-stones.

Observations on the state of an arch as it rests on the centring.

While all the arch-stones lie on the centring, the lower courses are also leaning pretty strongly on each other. But the mortar is hardly compressed in the joints, and least of all in the joints near the crown. Suppose the arch to be Catenarean, or of any other shape that is perfectly equilibrated: when the centring is gradually withdrawn, all the arch-stones follow it. Their wedge-like form makes this impossible, without the middle ones squeezing the lateral ones aside. This compresses the mortar between them. As the stones thus come nearer to each other, those near the crown must descend more than those near the haunches, before every stone has lessened its distance from the next by the same quantity, for example, by the hundredth part of an inch. This circumstance alone must cause a sinking in the crown, and a change of shape. But the joints near the crown are *already* more open than those near the haunches. This produces a still greater change of form before all is settled. Some masons endeavour to remedy, or at least to diminish this, by using no mortar in the joints near the crown. They lay the stones dry, and even force them together by wedges and blocks laid between the stones on opposite sides of the crown: they afterwards pour in fine cement. This appears a good practice. Perronet rejects it, because the wedging sometimes breaks the stones. We should not think this any great harm, because the fracture will make them close where they would otherwise lie hollow. But, after all our care, there is still a sinking of the crown of the arch. By gradually withdrawing the centring, the joints close, the arch-stones begin to butt on each other, and to force aside the lateral courses. This abutment gradually increasing, the pressure on the haunches of the centring is gradually diminished by the mutual abutment, and ceases entirely in that course, which is the lowest that formerly pressed it; it then ceases in the course above, and then in the third, and so on. And in this manner not only the centring quits the arch gradually, from the bottom to the top, *by its own retiring from it*, but the arch also quits the centring *by changing its shape*. If the centring were now pushed up again, it would touch the arch first at the crown; and it must *lift up* that part gradually, before it come again in contact with the haunches. It is evident, therefore, that an arch built on a centre of a shape perfectly suited to equilibration, will not be in equilibrio when the centring is removed. It is therefore necessary to form the centring in such a manner, by raising the crown, that it shall *leave* the arch of a proper form. This is a very delicate task, requiring a previous knowledge of the ensuing change of form. This cannot be ascertained by the help of any theory we are acquainted with.

Centre.

But suppose this attained, there is another difficulty. While the work advances, the centring is warped by the load laid on it, and continually increasing on each side. The first pressure on the centring forces down the haunches, and raises the crown. The arch is therefore less curved at the haunches than is intended: the joints, however, accommodate themselves to this form, and are close, and filled with mortar. When the masons approach the middle of the arch, the frame sinks there, and rises up at the haunches. This opens all the joints in that place on the *upper* side. By the time that the keystones are set, this warping has gone farther, and joints are opened on the *under* side near the crown. It is true, we are here speaking rather of an extreme case, when the centring is *very* flexible; but this occurred to M. Perronet in the two great bridges of Neuilly and of Mantz. In this last one the crown sunk above a foot before the key was set, and the joints at the haunches opened above an inch *above*, while some nearer the crown opened near a quarter of an inch *below*.

A delicate business to strike the centring.

In this condition of things, it is a delicate business to strike the centring. Were it removed in an instant, all would probably come down; for the arch-stones are not yet abutting on each other, and the joints in the middle are open below. M. Perronet's method appears to us to be very judicious. He began to detach the centring at the very bottom, on each side equally, where the pressure on the centring is very slight. He cut away the blocks which were immediately under each arch-stone. He proceeded gradually upwards in this way with some speed, till all was detached that had been put out of shape by the bending of the centring. This, being no longer supported, sunk inward, till it was stopped by the abutment which it found on the arch-stones near the crown, which were still resting on their blocks. During part of this process, the open joints opened still more, and looked alarming. This was owing to the removal of the load from the haunches of the centring. This allowed the crown to sink still more, by forcing out the arch-stones at the haunches. He now paused some days, and during this time the two haunches, now hanging in the air, gradually pressed in toward the centring, their outer joints closing in the meanwhile. The haunches were now pressing pretty hard on the arch-stones nearer the crown. He then proceeded more slowly, destroying the blocks and bridgings of these upper arch-stones. As soon as he destroyed the support of one, it immediately yielded to the pressure of the haunch; and if the joint between it and the one adjoining toward the crown happened to be open, whether on the under or the upper side, it immediately closed on it. But in proceeding thus, he found every stone sink a little while it closed on its neighbour; and this was like to produce a ragged soffet, which is a deformity. He therefore did not allow them to sink so much. In the places of the blocks and bridgings which he had cut away, he set small billets, standing on their ends, between the centring and the arch-stones. These allowed the pendulous arch to push toward the crown without sensibly descending; for the billets were pushed out of the perpendicular, and some of them tumbled down. Proceeding in this way, he advanced to the very next course to the keystone on each side, the joints closing all the way as he advanced. The last job was very troublesome; we mean the detaching of the three uppermost courses from the centring; for the whole elasticity of the centring was now trying to unbend, and pressing hard against them. He found that they were lifted up; for the joints beyond them, which had closed completely, now opened again below; but this job was finished in one day, and the centre sprung up two or three inches, and the whole arch sunk about six inches. This was an anxious time; for he dreaded the great momentum of such a vast mass of matter. It was hard to say where it would stop. He had the pleasure to see that it stopped very soon, settling slowly as the mortar was compressed, and after one or two days settling no more. This settling was very considerable, both in the bridge at Neuilly and in that at Mantz. In the former, the sinking during the work amounted to thirteen inches. It sunk six inches more when the blocks and bridgings were taken out, and one and a half when the little standards were destroyed, and one and a fourth more next day; so that the whole sinking of the *pendulous* arch was nine inches and a half, besides what it had sunk by the bending and compression of the centring.

The crown of the centring was an arch of a circle described with a radius of 150 feet; but by the sinking of the arch its shape was considerably changed, and about sixty feet of it formed an arch of a circle whose radius was 244 feet. Hence M. Perronet infers that a semicircle of 500 feet span may be erected. It would no doubt be stronger than this arch, because its greater horizontal thrust would keep the stones firmer together. The sinking of the arches at Mantz was not quite so great, but every thing proceeded in the same way. It amounted in all to twenty and a half inches, of which twelve inches were owing to the compression and bending of the centring.

The foregoing observations exemplified.

In fig. 5, No. 1, may be observed an indication of this procedure of the masonry. There may be noticed a horizontal line *ac*, and a diagonal *ab*. These are supposed to be drawn on the masonry as it would have stood had the frames not yielded during the building. The dotted line A *b′c′* shows the shape which it took by the sinking of the centring. The dotted line on the other side was actually drawn on the masonry when the keystone was set; and the wavy black line on the same side shows the form which the dotted line took by the striking of the centring. The undulated part of this line cuts its former position a little below the middle, going without it below, and falling within it above. This shows very distinctly the movement of the whole masonry, distinguishing the parts that were forced out and the parts which sunk inward.

We presume that the practical reader will think this account of the internal movements of a stupendous arch very instructive and useful. As M. Perronet observed it to be uniformly the same in several very large arches which he erected, we may conclude that it is the general process of nature. We by no means have the confidence in the durability or solidity of his arches which he prudently professes to have. We have conversed with some very experienced masons, who have also erected very great arches, and in very difficult situations, which have given universal satisfaction; and we have found them uniformly of opinion, that an arch which has settled to such a proportion of its curvature as to change the radius from 150 to 244 feet, is in a very hazardous situation. They think the hazard the greater because the span of the arch is so great in proportion to its weight (as they express it very emphatically) or its height. The weight, say they, of the haunches is too small for forcing together the keystones, which have scarcely any wedgelike form to keep them from sliding down. This is very good reasoning, and expresses very familiar notions. The mechanician would say that the horizontal thrust at the crown is too small. When we questioned them about the propriety of M. Perronet's method of removing the centring, they unanimously approved of its general principle, but said that it was very ticklish indeed in the execution. The cases which he narrates were new to them. They should have almost despaired of success with arches which had gone so much out of shape by the bending of the centres; because, said

they, the slope of the centring, to a great distance from the crown, was so little, that the arch-stones could not slide outwards along it, to close even the under side of the joints which had opened above the haunches; so that *all* the arch-stones were at too great a distance from each other; and a great and *general* subsiding of the whole was necessary for bringing them even to touch each other. They had *never* observed such bendings of the centrings which they had employed, having never allowed themselves to contract the feet of their trusses into such narrow spaces. They observed that nothing but lighters with their masts down can pass under the trusses, and that the sides must be so protected by advanced works from the accidental shock of a loaded boat, that there cannot be left room for more than one. They added, that the bridges of communication necessary for the expeditious conducting of the work made all this supposed roominess useless; besides, the business can hardly be so urgent and crowded anywhere as to make the passage through every arch indispensably necessary. Nor was the inconvenience of this obstruction greatly complained of during the erection of Westminster or Blackfriars Bridges. Nothing should come in competition with the *undoubted* solidity of the centring and the future arch; and all boasting display of talent and ingenuity by an engineer, in the exhibition of the wonders of his art, is misplaced here.

These appeared to us good reasons for preferring the more cautious, and incomparably more secure, construction of Mr Mylne, in which the breadth given to each base of the trusses permitted a much more effective disposition of the abutting timbers, and also enabled the engineer to make it incomparably stiffer; so that no change need be apprehended in the joints which have already closed, and in which the mortar has already taken its set, and commenced an union that never can be restored if it be once broken in the smallest degree, no not even by greater compression.

The connection that is formed by mortar of lime, &c.

Here we beg leave to mention our notions of the connection that is formed by mortar composed of lime or gypsum. We consider it as consisting chiefly, if not solely, in a crystallization of the lime or gypsum and water. As much water is taken up as is necessary for the formation of the crystals during their gradual conversion into mild calcareous earth or alabaster, and the rest evaporates. When the free access of air is absolutely prevented, the crystallization never proceeds to that state, even although the mortar becomes extremely dry and hard. We had an opportunity of observing this accidentally, when passing through Maestricht in 1770, while they were cutting up a massy revetment of a part of the fortifications more than three hundred years old. The mortar between the bricks was harder than the bricks (which were Dutch clinkers, such as are now used only for the greatest loads); but when mixed with water it made it lime-water, seemingly as strong as if fresh lime had been used. We observed the same thing in one small part of a huge mass of ancient Roman work near Romney, in Kent; but the rest, as well as all the *very old* mortar that we have seen, was in a mild state, and was generally much harder than what produced any lime-water. Now when the mortar in the joints has begun its first crystallization, and is allowed to remain in perfect rest, we are confident that the subsequent crystals, whether of lime, or of calcareous earth, or of gypsum, will be much larger and stronger than can ever be produced if they are once broken; and the farther that this crystallization has been carried, that is, the harder that the mortar has become, less of it remains to take any new crystallization. Why should it be otherwise here than in every other crystallization that we are acquainted with?

Necessity of keeping the joints in their first state.

We think therefore that it is of great consequence to keep the joints in their *first* state if possible; and that the strength, in as far as it depends on the mortar, is greatly diminished by their opening; especially when the mortar has acquired considerable hardness, which it will do in a month or six weeks, if it be good. The cohesion given by mortar is indeed a mere trifle, when opposed to a force which tends to open the joints, acting, as it generally does, with the transverse force of a lever. But in situations where the overload on any particular arch-stones tends to push them down through between their neighbours, like wedges, the cohesion of the mortar is then of very great consequence.

We must make another observation. M. Perronet's ingenious process tended very effectually to close the joints. In doing this the forces which he brought into action had little to oppose them; but as soon as they were closed the contact of the parts formerly open opposed an obstruction incomparably greater, and immediately balanced a force which was but just able to turn the stone gently about the two edges in which it touched the adjoining stones. This is an important remark, though seemingly very trifling; and we wish the practitioner to have a very clear conception of it; but it would take a multitude of words to explain it. It is worth an experiment. Form a little arch of wooden blocks; and form one of these so, that when they are all resting on the centring, it may be open at the outer joint: remove the centring; then press on the arch at some distance from the open joint: you will find that a very small pressure will make the arch bend till that joint closes. Press a little harder, and the arch will bend more, and the next joint will open. Thus you will find, that by pressing alternately on each side of the open joint, that stone can easily be made to flap over to either side; and that immediately after this is done the resistance increases greatly. This shows clearly that a very moderate force, judiciously employed, will close the joints, but will not press the parts strongly together. The joints therefore are *closed*, but *no more than closed*, and are hanging only by the edges by which they were hanging while the joints were open. The arch, therefore, though apparently close and firm, is but loose and tottering. M. Perronet says that his arches were firm, because hardly a stone was observed to chip or splinter off at the edges by the settlement. But he had done every thing to prevent this, by digging out the mortar from between the headers, to the depth of two inches, with saws made on purpose. But we are well informed, that before the year 1791 (twenty years after the erection) the arches at Neuilly had sunk very sensibly, and that very large splinters had flown off in several places. It could not be otherwise. The original construction was too bold; we may say needlessly and ostentatiously bold. A very gentle slope of the roadway, which would not have slackened the mad gallop of a ducal carriage, nor sensibly checked the laborious pull of a loaded waggon, and a proper difference in the size of the arches, would have made this wonderful bridge incomparably stronger, and also much more elegant and pleasing to the eye. Indeed it is far from being as handsome as it might have been. The ellipse is a most pleasing figure to every beholder; but this is concealed as much as possible, and it is attempted to give the whole the appearance of a tremendous lintel. It has the oppressive look of danger. It will not be of long duration. The bridge at Mantz is still more exceptionable, because its piers are tall and slender. If any one of the arches fails, the rest must fall in a moment. An arch of Blackfriars Bridge might be blown up without disturbing its neighbours.

M. Perronet's constructions too bold.

M. Perronet mentions another mode of striking the

Centre.

A bad method of striking the centre.

centring, which he says is very usual in France. Every second bridging is cut out. Some time after every second of the remainder; after this every second of the remainder; and so on till all are removed. This is never practised in this country, and is certainly a very bad method. It leaves the arch hanging by a number of distant points; and it is wonderful that any arch can bear this treatment.

The common method in Britain.

Our architects have generally proceeded with extreme caution. Wherever they could they supported the centring by intermediate pillars, even when it was a trussed centre, having a tie-beam reaching from side to side. The centre was made to rest, not immediately on these pillars, but on pieces of timber formed like acute wedges, placed in pairs, one above the other, and having the point of the one on the thick end of the other. These wedges were well soaped and rubbed with black lead, to make them slippery. When the centres are to be struck, men are stationed at each pair of the wedges with heavy mauls. They are directed to strike together on the opposite wedges. By this operation the whole centring descends together; or when any part of the arch is observed to have opened its joints on the upper side, the wedges below that part are slackened. The framing may perhaps bend a little, and allow that part to subside. If any part of the arch is observed to open its joints on the under side, the wedges below that part are allowed to stand after the rest have been slackened. By this process the whole comes down gradually, and as slowly as we please, and the defects of every part of the arch may be attended to. Indeed the caution and moderation of our builders have commonly been such, that few defects have been allowed to show themselves. We are but little acquainted with joints opening to the extent of two inches, and in such a case would probably lift every stone of the arch again.[1] We have not employed trussed centrings so much perhaps as we should have done; nor do we see their advantage (speaking as mere builders) over centres supported all over, and unchangeable in their form. Such centres must bend a little, and require loading on the middle to keep them in shape. Their compression and their elasticity are very troublesome in the striking of the centres in M. Perronet's manner. The elasticity is indeed of use when the centres are struck in the way now described.

These observations on the management of the internal movements of a great arch will enable the reader to appreciate all the merit of Mr Mylne's very ingenious construction. We proceed therefore to complete our description.

The excellence of Mr Mylne's method.

The gradual enlargement of the base of the piers of Blackfriars Bridge enabled the architect to place a series of five posts C, C, C, C, C, one on each step of the pier, the ingenious contexture of which made it like one solid block of stone. (See ARCH.) These struts were gradually more and more oblique, till the outer one formed an obtuse angle with the lowest side of the interior polygon of the truss. On the top of these posts was laid a sloping seat or beam D of stout oak, the upper part of which was formed like a zig-zag scarfing. The posts were not perpendicular to the under side of the seat. The angles next the pier were somewhat obtuse. Short pieces of wood were placed between the heads of the posts, but not mortised into them, to prevent them from slipping back. Each face of the scarf was covered with a thick and smooth plate of copper. The feet of the truss were mortised into a similar piece F, which may be called the SOLE of the truss, having its lower side notched in the same manner with the upper side of D, and like it covered with copper. Between these two lay the STRIKING WEDGE E, the faces of which corresponded exactly with the slant faces of the seat and the sole. The wedge was so placed that the corresponding faces touched each other for about half of their length. A block of wood was put in at the broad end or base of this wedge, to keep it from slipping back during the laying of the arch-stones. Its outer end E was bound with iron, and had an iron bolt several inches long driven into it. The head of this bolt was broad enough to cover the whole wood of the wedge within the iron ferule.

We presume that the reader by this time foresees the use of this wedge. It is to be driven in between the sole and the seat, having first taken out the block at the base of the wedge. As it advances into the wider spaces, the whole truss must descend, and be freed from the arch; but it will require prodigious blows to drive it back. Mr Mylne did not think so, founding his expectation on what he saw in the launching of great ships, which slide very easily on a slope of ten or twelve degrees. He rather feared, that taking out the block behind would allow the wedge to be pushed back at once, so that the descent of the truss would be too rapid. However, to be certain of the operation, he had prepared an abundant force in a very ingenious manner. A heavy beam of oak, armed at the end with iron, was suspended from two points of the centre like a battering ram, to be used in the same manner. Nothing could be more simple in its structure, more powerful in its operation, or more easy in its management. Accordingly the success was to his wish. The wedge did not slip back of itself; and very moderate blows of the ram drove it back with the greatest ease. The whole operation was over in a very few minutes. The spectators had suspected that the space allowed for the recess of the wedge was not sufficient for the settlement of the arch, but the architect trusted to the precautions he had taken in its construction. The reader, by turning to the article ARCH, will see that there was only the arch LY (Plate XLIX., fig. 1) which could be expected to settle; accordingly, the recess of the wedge was found to be much more than was necessary. However, had this not been the case, it was only necessary to take out the pieces between the posts below the seat, and then to drive back the heads of the struts; but this was not needed, we believe, in any of the arches. We are well assured that none of the arches sunk an inch and a half. The great arch of one hundred feet span did not sink one inch at the crown. It could hardly be perceived whether the arch quitted the centring gradually or not, so small had been the changes of shape. We have no hesitation in saying, that, if we except some waste of great timber by uncommon joggling, the whole of this performance is the most perfect of any that has come to our knowledge.[2]

The subject of this article connected with the construction of wooden bridges.

The subject which we have been considering is very closely connected with the construction of wooden bridges. These are not always constructed on the sole principles of equilibrium by means of mutual abutment. They are stiff frames of carpentry, where, by a proper disposition, beams are put into a state of extension, as well as of compression, so as to stand in place of solid bodies as big as the

---

[1] The writer of this article can only say, that, after much inquiry, he has no information of any arch being received from the builder as sufficient that had suffered half the change of shape mentioned by M. Perronet. The arch of Dublin Bridge, built by an excellent, but a very private mason, Mr Steven, is 105 feet wide, with only twenty-two feet rise. It was erected, but not on a trussed centring, without changing one full inch in its elevation; and when the centring was removed, it sunk only $1\frac{3}{4}$th inch, and about half an inch more when the parapets were added and the bridge completely finished.

[2] The reader will find a representation of the centring of Waterloo Bridge in Plate CXLV. article BRIDGE.

Centre.

spaces which the beams inclose; and thus we are enabled to couple two, three, or four of these together, and set them in abutment with each other like mighty arch-stones. We shall close this article, therefore, with two or three specimens of wooden bridges, disposed in a series of progressive composition, so as to serve as a sort of introduction to the art in general, and furnish a principle which will enable the intelligent and cautious artist to push it with confidence as far as it can go.

The general problem is this. Suppose that a bridge is to be thrown over the space AB (fig. 9), and that this is too wide for the strength of the size of timber which is at our command; how may this beam AB be supported with sufficient effect? There are but two ways in which the middle point C, where the greatest strain is, can be supported: 1. It may be suspended by two ropes, iron rods, or wooden ties, DC, EC, made fast to two firm points D, E, above it; or it may rest on the ridge of two rafters *d* C, *e* C, which rest on two firm points *d*, *e*, below it. 2. It may be supported by connecting it with a point so supported; and this connection may be formed, either by suspending it from this point, or by a post resting on it. Thus it may hang, by means of a rod or a king-post FC, from the ridge F of two rafters AF, BF; or it may rest on the strut C *f*, whose lower extremity *f* is carried by the ropes, rods, or wooden ties A *f*, B *f*.

Whichsoever of these methods we employ, it follows, from the principles of carpentry, that the support given to the point C is so much the more powerful, as we make the angle DCE, or *d* C *e*, or the equivalent angles AFB, or A *f* B, more acute.

The usual and simplest method of constructing such bridges.

Each of these methods may be supposed equally strong. Our choice will depend chiefly on the facility of finding the proper points of support D, E, *d*, *e*; except in the second case, where we require no fixed points but A and B. The simple forms of the first case require a great extent of figure. Very rarely can we suspend it from points situated as D and E. It is even seldom that we have depth enough of bank to allow the support of the rafters *d* C, *e* C, but we can always find room for the simple truss AFB. This, therefore, is the most usually practised.

In the construction, we must follow the maxims and directions prescribed in the article CARPENTRY and the article ROOF. The beams FA, FB, must be mortised into AB in the firmest manner, and there secured with straps and bolts; and the middle must hang by a strap attached to the king-post FC, or to the iron rod that is used for a king-post. No mortising in the point C must be employed; it is unnecessary, and it is hurtful, because it weakens the beam, and because it lodges water, and soon decays by rot. The best practice is not to suspend the beam immediately by this strap, but to let it rest, as in fig. 10, on a beam C, which crosses the bridge below, and has its other end supported in the same manner by the other truss.

It is evident that the length of the king-post has no effect on the support of C. We may therefore contract every thing, and preserve the same strength of support, by finding two points *a* and *b* (fig. 11) in the banks, at a moderate distance below A and B, and setting up the rafters *a* F, *b* F, and suspending C from the shortened king-post. In this construction, when the beam AB rests on a cross bearer, as is drawn here, the struts *a* F, *b* F, are kept clear of it. No connection between them is necessary, and it may be hurtful, by inducing cross strains on both. It will, however, greatly increase the stiffness of the whole. This construction may safely be loaded with ten times the weight that AB can carry alone.

Suppose this done, and that the scantling of AB is too weak for carrying the weight which may be brought on the parts AC, CB. We may now truss up each half, as in fig. 12, and then the whole will form a handsome bridge, of the simplest construction possible. The intersections of the secondary braces with those of the main truss will form a hand-rail of agreeable figure.

Centre.

An improvement of that method.

We are not confined to the employment of an entire piece AB, nor to a rectilineal form. We may frame the bridge as in fig. 13, and in this form we dissuade from allowing any connection with the middle points of the main braces. This construction also may be followed till each beam AC and CB is loaded to ten times what it can safely bear without the secondary trussing.

Another method.

There is another way by which a bridge of one beam may be supported beyond the power of the first and simplest construction. This is represented in fig. 14 and fig. 15. The truss-beam FG should occupy one third of AB. The advantage of this construction is very considerable. The great elevation of the braces, which is a principal element of the strength, is preserved, and the braces are greatly shortened.

This method may be pushed still farther, as in fig. 16.

These methods combined.

And all these methods may be combined, by joining the constructions of fig. 14 and fig. 15 with that of fig. 16.

In all of them there is much room for the display of skill in the proper adjustment of the scantling of the timber, and the obliquity of the braces to the lengths of the different bearings. A very oblique strut, or a slender one, will suffice for a small load, and may often give an opportunity to increase the general strength; while the great timbers and upright supports are reserved for the main pressures. Nothing will improve the composition so much as reflecting progressively, and in the order of these examples, on the whole. This alone can preserve the great principle in its simplicity and full energy.

The elements of all that can be done in this art.

These constructions are the elements of all that can be done in the art of building wooden bridges, and are to be found more or less obviously and distinctly in all attempts of this kind. We may assert, that the more obviously they appear, the more perfect the bridge will be. It is astonishing to what extent the principle may be carried. We have seen a bridge of forty-two feet span formed of two oak trusses, the biggest timber of which did not exceed six inches square, bearing with perfect steadiness and safety a waggon loaded with more than two tons, drawn by four stout horses. It was framed as fig. 16 nearly, with the addition of the dotted lines, and was near thirty years old, protected, however, from the weather by a wooden roof, as many bridges in Germany are.

We recollect another in the neighbourhood of Stettin, which seemed constructed with great judgment and spirit. It had a carriage-road in the middle, about twenty feet, we think, wide, and on each side a footway about five feet wide. The span was not less than sixty feet, and the greatest scantling did not appear to exceed ten inches by six.

This bridge consisted of four trusses, two of which formed the outside of the bridge, and the other two made the separation between the carriage-road and the two footways. We noticed the construction of the trusses very particularly, and found it similar to the last, except in the middle division of the upper truss, which, being very long, was double trussed, as in fig. 17.

The reader will find in that volume of Leupold's *Theatrum Machinarum*, which he calls *Theatrum Pontificum*, many specimens of wooden bridges, which are very frequent in the champaign parts of Germany. They are not, in general, models of mechanic art; but the reflecting reader, who considers them *carefully*, will pick up here and there subordinate hints, which are ingenious, and may sometimes be useful.

Centre.

What we have now exhibited are not to be considered as models of construction, but as elementary examples and lessons, for leading the reader systematically into a thorough conception of the subject.

A wonderful bridge in Switzerland.

We cannot quit the subject without taking notice of a very wonderful bridge at Wittingen in Switzerland, slightly described by Mr Coxe (*Travels*, vol. i. 132). It is of a construction more simple still than the bridges we have been describing. The span is 230 feet, and it rises only twenty five. The sketch (fig. 18) will make it sufficiently intelligible. ABC is one of two great arches, approaching to a Catenarian shape, built up of seven courses of solid logs of oak, in lengths of twelve or fourteen feet, and sixteen inches or more in thickness. These are all picked of a natural shape, suited to the intended curve; so that the wood is nowhere cut across the grain to trim it into shape. These logs are laid above each other, so that their abutting joints are alternate like those of a brick wall; and it is indeed a wooden wall simply built up, by laying the pieces upon each other, taking care to make the abutting joints as close as possible. They are not fastened together by pins or bolts, or by scarfings of any kind. They are, however, held together by iron straps, which surround them, at the distance of five feet from each other, where they are fastened by bolts and keys.

These two arches having been erected (by the help, we presume, of pillars, or a centring of some kind), and well butted against the rock on each side, were freed from their supports, and allowed to settle. They are so placed that the intended road *a b c* intersects them about the middle of their height. The roadway is supported by cross joists, which rest on a long horizontal summer beam. This is connected with the arches on each side by uprights bolted into them. The whole is covered with a roof, which projects over the arches on each side to defend them from the weather. Three of the spaces between these uprights have struts or braces, which give the upper work a sort of trussing in that part.

This construction is simple and artless; and appears, by the attempt to truss the ends, to be the performance of a person ignorant of principle, who has taken the whole notion from a stone arch. It is, however, of a strength much more than adequate to any load that can be laid on it. Mr Coxe says, but does not explain how, that it is so contrived that any part of it can be repaired independently of the rest. It was the last work of one Ulrich Grubenhamm of Tuffen, in the canton of Appenzel, a carpenter without education, but celebrated for several works of the same kind; particularly the bridge over the Rhine at Schaffhausen, consisting of two arches, one of 172 and the other of 193 feet span, both resting on a small rock near the middle of the river.

While writing this article, we got an account of a wooden bridge erected in North America, in which this simple notion of Grubenhamm's is mightily improved. The span of the arch was said to exceed 250 feet, and its rise exceedingly small. The description we got is very general, but sufficient, we think, to make it perfectly intelligible.

Another in North America.

In fig. 19, DD, EE, FF, are supposed to be three beams of the arch. They consist of logs of timber of small lengths, suppose of ten or twelve feet, such as can be found of a curvature suited to its place in the arch without trimming it across the grain. Each beam is double, consisting of two logs applied to each other side to side, and *breaking joint*, as the workmen term it. They are kept together by wedges and keys driven through them at short intervals, as at K, L, &c.

The manner of joining and strongly binding the two side pieces of each beam is shown in fig. 20. The mortise *a i c b* and *d c i o*, which is cut in each half beam, is considerably longer on the outside than on the inside, where the two mortises meet. The two keys, BB and CC, are formed, each with a notch *b c d*, or *a i o*, on its side; which notch fits one end of the mortise. The inner side of the key is straight, but so formed that when both keys are in their places, they leave a space between them wider at one end than at the other. A wedge AA, having the same taper as the space just mentioned, is put into it and driven hard. It is evident that this must hold the two logs firmly together.

Centre.

This is a way of uniting timber not mentioned in the article CARPENTRY, and it has some peculiarities worthy of notice. In the first place, it may be employed so as to produce a very strong lateral connection, and would then co-operate finely with the other artificial methods of scarfing and tabling that we described in the article referred to. But it requires nice attention to some circumstances of construction to secure this effect. If the joints are accurately formed to each other, as if the whole had been one piece divided by an infinitely thin saw, this manner of joining will *keep* them all in their places. But no driving of the wedge AA will make them the firmer, or cause one piece to press hard on the other. If the abutment of two parts of the half beam is already close, it will remain so; but if open in the smallest degree, driving of the wedge will not make it tighter. In this respect, therefore, it is not so proper as the forms described in CARPENTRY.

In order that the method now described may have the effect of *drawing* the halves of the beams together, and of keeping them hard squeezed on each other, the joints must be made so as not to correspond exactly. The prominent angle *a i o* (fig. 21), formed by the ends of the two half mortises, must be made a little more obtuse than the angle *a f o* of the notch of the key which this prominence is intended to fill up. Moreover, the opposite side *e t* of this key should not be quite straight, but a very little convex. With these precautions, it is easy to see that, by driving the wedge AA, we cause the notch *a f o* to take hold, first at the two points *a* and *o*, and then, by continuing to drive the wedge, the sides *a f*, *o f*, of the notch gradually compress the wood of the half beams, and press them on each other. By continuing to drive the wedge, the mutual compression of the key and the beam squeezes all together, and the space *a f o i* is completely filled up. We may see, from this process, that the mutual compression and drawing together of the timber will be greater in proportion as we make the angle *a i o* more prominent, and its corresponding angle *a f o* more deep; always taking care that the key shall be thick enough not to break in the narrow part.

This adjustment of the keys to the mortise is necessary on another account. Supposing the joints to fit each other exactly before driving the wedge, and that the whole shrinks a little by drying—by this the angle *a i o* will become more prominent, and the angle *a f o* will become more shallow; the joint will open at *a* and *o*, and the mutual compressure will be at an end.

We may also observe that this method will not give any additional firmness to the abutments of the different lengths employed to piece out the arch-beam; in which respect it differs materially from the other modes of joining timber.

Having shown how each beam is pieced together, we must now show how a number of them are united, so as to compose an arch of any thickness. This is done in the very same way. The beams have other mortises worked out of their inner sides, half out of each half of the beam. The ends of the mortises are formed in the same way with those already described. Long keys, BB, CC (fig. 19), are made to fit them properly, the notches being placed

so as to keep the beams at a proper distance from each other. It is now plain that driving in a long wedge AA will bind all together.

In this manner may an arch be extended to any span, and made of any thickness of arching. The bridge over Portsmouth river in North America was more than 250 feet in length, and consisted of several parallel arches of beams. The inventor (we think his name is Bludget) said that he found the strength so great that he could with perfect confidence make one of four times the span.

We admire the ingenuity of this construction, and think it very effectual for bringing the timbers into firm and uniform abutment; but we imagine that it requires equilibration, because it is extremely flexible. There is nothing to keep it from bending, by an inequality of load, but the transverse strength of the beams. The keys and wedges can have very little power to prevent this bending. The distance between the beams will also contribute little or nothing to the stiffness; nay, we may imagine that a great distance between them will make the frame more flexible. Could the beams be placed so near each other that they could be somehow joggled on each other, the whole would be stiffer; but at present they will bend like the plates of a coach-spring. But nothing hinders us from adding diagonal pieces to this construction, which will give it any degree of stiffness, and will enable it to bear any inequality of loading. When completed in this manner, we imagine that it will be at least equal to any construction that has yet been thought of. One advantage it possesses that is very precious; any piece that fails may be taken out, and replaced by another, without disturbing the rest, and without the smallest risk. On the whole, we think it a very valuable addition to British carpentry. The method here practised, both for joining the parts of one beam and for framing the different beams together, suggests the most firm and light constructions for dome-roofs that can be conceived; incomparably superior to any that have yet been erected. The whole may be framed, without a nail or a spike, into one net-like shell, that cannot even be pulled in pieces.

Bridges combined by simple addition or by composition.

When the width of the river exceeds what is thought practicable by a single truss, we must then combine, either by simple addition or by composition, different trusses together. We compose a bridge by simple addition when we make a frame of carpentry of an unchangeable and proper shape, to serve as one of the arch-stones of a bridge of masonry. This may easily be comprehended by looking at fig. 22. Each of the frames A, B, C, D, must be considered as a separate body, and all are supported by their mutual abutment. The nature of the thing is not changed, although we suppose that the rails of the frame B, instead of being mortised into an upright $b\,b'$, unconnected with the frame C, is mortised into the upright $c\,c'$ of that frame; the direction and intensity of the mutual pressures of the two frames are the same in both cases; accordingly, this is a very common form of small wooden bridges. It is usual, indeed, to put diagonal battens into each; but we believe that this is more frequently done to please the eye than to produce an unalterable shape of each frame.

To an unskilful carpenter this bridge does not seem essentially different from the centring of M. Hupeau for the bridge of Orleans; and indeed, in many cases, it requires reflection, and sometimes very minute reflection, to distinguish between a construction which is only an addition of frame to frame till the width be covered, from a construction where one frame works on the adjoining one transversely, pushing it in one part, and drawing it in another. The ready way for an unlettered artist to form a just notion of this point, is to examine whether he may saw through the connecting piece $b'b$ from one end to the other, and make them two separate frames. Whenever this cannot be done without that part opening, it is a construction by composition. Some of the beams are on the stretch; and iron straps, extending along both pieces, are necessary for securing the joint. The bridge is no longer a piece of masonry, but a performance of pure carpentry, depending on principles peculiar to that art. Equilibration is necessary in the first construction; but, in the second, any inequality of loading is made ineffectual for hurting the edifice, by means of the stretch that is made to operate on some other piece. We are of opinion that this most simple employment of the distinguishing principle of carpentry, by which the beams are made to act as ties, will give the most perfect construction of a wide bridge. One polygon alone should contain the whole of the abutments, and one other polygon should consist entirely of ties; and the beams which form the radii, connecting the angles of the two polygons, complete the whole. By confining the attention to these two simple objects, the abutments of the outer polygon, and the joints of the inner one, may be formed in the most simple and efficient manner, without any collateral connections and dependencies, which divide the attention, increase the complication, and commonly produce unexpected and hurtful strains. It is for this reason that we have so frequently recommended the centring of the bridge of Orleans. Its office will be completely performed by a truss of the form of fig. 23, where the polygon ABCDEF, consisting of two layers of beams, if one is not sufficient, contains the whole abutments, and the other A $b\,c\,d\,e$ F is nothing but an iron rod. In this construction, the obtuseness of the angles of the lower polygon is rather an advantage. The braces G c, G d, which are wanted for trussing the middle of the outer beams, will effectually secure the angles of the exterior polygon against all risk of change. The reader must perceive that we have now terminated in the construction of the Norman roof. We indeed think it the best general form, when some moderate declivity is not an insuperable objection. When this is the case, we recommend the general plan of the centring of the bridge of Orleans. We would make the bridge (we speak of a great bridge) consist of four trusses, two to serve as the outsides of the bridge, and two inner trusses, separating the carriage-way from the footpaths. The road should follow the course of the lower polygon, and the main truss should form the rails. It might look strange, but we are here speaking of strength; and evident, but not unwieldy strength, once it becomes familiar, is the surest source of beauty in all works of this kind. (J. R.)

How to distinguish bridges formed according to these different methods.

The best general form of a wooden bridge.

Centre *of Gravity*, in *Mechanics*, that point about which all the parts of a body exactly balance each other.

Centre *of Motion*, that point which remains at rest while all the other parts of a body move round it.

CENTRIFUGAL Force (*centrum* and *fugio* to flee), that force by which all bodies that move round another body in a curve tend to fly off from the axis of their motion in a tangent to the periphery of the curve.

CENTRIPETAL Force (*centrum* and *peto* to move towards), that force by which a body is impelled towards a centre. In circular motion the centrifugal and centripetal forces constantly balance each other, otherwise the revolving body would either approach or recede from the centre, as one or the other prevailed.

CENTUMVIRI, in *Roman Antiquity*, judges appointed to decide common causes among the people. Three were

chosen out of each tribe; and, though five more than a hundred, were nevertheless called *centumviri*, from the round number *centum*, a hundred. The extent of their powers in civil causes has not been completely ascertained. Some have asserted that they also took cognizance in criminal matters, but this is doubtful.—(See Hollweg, *Über die Compentenz des Centumviralgerichts;* Tigerström, *De Judicibus apud Romanos.*)

CENTURION (*centurio*), among the Romans, an officer in the infantry, who commanded a century or a hundred men. In order to have a proper notion of the centurions, it must be remembered that every one of the thirty manipuli in a legion was divided into two *ordines*, or ranks; and consequently the three bodies of the hastati, principes, and triarii, into twenty orders and ten manipuli each. Now, every manipulus was allowed two centurions, or captains, one to each order or century; and, to determine the point of priority between them, they were created at two different elections. The thirty who were first made always took the precedence of their fellows; and therefore commanded the right-hand *ordines*, as the others did the left. The triarii, or *pilani* (so called from their weapon the *pilum*), being esteemed the most honourable, had their centurions elected first, next to them the principes, and afterwards the hastati; whence they were called *primus et secundus pilus*, *primus et secundus princeps*, *primus et secundus hastatus*, and so on. Here it may be observed, that *primi ordines* is sometimes used in historians for the centurions of these orders; and the centurions are sometimes styled *principes ordinum*, and *principes centurionum*. See ARMY, vol. iii. p. 631.

CENTURY, in a general sense, anything divided into, or consisting of, a hundred parts: also a period of 100 years. In the modern computation of time from the incarnation of Christ, the word is used in a particular sense to denote some term of a hundred years subsequent to that event; as the first century, the second century, &c.

CENTURY, in *Antiquity*, a division of the Roman people for the purpose of electing magistrates, enacting laws, or deliberating upon any public affair. They voted by centuries in order that their votes might be the more easily collected; and hence these assemblies were called *comitia centuriata*. The Roman cohorts were also divided into centuries.

CEORLES, one of the classes of the people among the Anglo-Saxons. Hence the word *churl*.

CEOS, the modern Zea, an island in the Ægean Sea, belonging to the group of the Cyclades, fourteen miles off the coast of Attica. It is celebrated as the birthplace of the lyric poets Simonides and Bacchylides; of the philosophers Prodicus and Ariston; and of the physician Erasistratus. There were anciently four towns of considerable importance in the island: Iulis, on the site of which stands the modern Zea; Coressia, the harbour of Iulis; Carthæa on the S.E., and Poieëssa on the S.W. shore. From the excellence of the laws regulating the life and morals of the ancient Ceans, the term "Cean laws" passed into a proverb. The present population of the island is about 4000.

CEPHAELIS, a newly instituted genus of the natural order of *Rubiaceæ* or cinchonaceous plants, containing many species; of which the most important is *C. ipecacuanha*, the root of which is employed in medicine as an emetic, expectorant, and diaphoretic. It is a native of the shady forests of Brazil.

CEPHALIC (κεφαλή, the head), pertaining to the head; as cephalic medicines, remedies for disorders in the head.

CEPHALONIA. See IONIAN ISLANDS.

CERAM (termed Sirang by the natives), a large and beautiful island, forming part of the government of the Moluccas, and situated between 3. 20. and 3. 40. S. Lat., and 127. 59. and 130. 45. E. Long. Its superficial extent is 5500 square miles. A vast chain of mountains, varying in elevation from 6000 to 8000 feet, but with several peaks of even greater altitude, whose height has not been exactly ascertained, extends from the western to the eastern point of the island. A great number of rivers and torrents flow from these heights towards the southern coast, which is the most accessible to commerce. Ceram enjoys a most salubrious climate, and is remarkable for the great fertility of its soil. It is covered with a luxuriant vegetation; with spice trees of all kinds, which grow without culture; and with various descriptions of useful and ornamental wood. Ceram is divided among several chiefs; those in the north being governed by the resident of Amboyna, and those in the east by the resident of Banda. A considerable portion of the central district is held by the Sultan Djelalo, a native prince, who was at one time a stipendiary of the Dutch government; but, having engaged in piracy, was seized with his accomplices in 1832 and carried to Java. The population consists of the aboriginal Alfoeres, who inhabit the interior and northern districts, and of the Malays, who are settled upon the coast. The former are described as savage and ignorant idolaters, whose principal object of worship is an evil genius whom they little regard, and who band together in frequent incursions against the Mohammedan and Christian tribes on the coast. Their houses are of wood, elevated on posts about six feet high, and surrounded by an external gallery. A Dutch resident who visited the interior describes one of their *bialos*, in which the tribe meets to deliberate upon its affairs, as adorned with sacred stones and other objects of veneration, and also with a trophy of thirty-six human skulls, the common property of the tribe. The Malays inhabiting the coast are intrepid sailors, and undertake voyages in their large vessels, which are propelled by 30, 40, or even 60 rowers, to the isles of Soende, Singapore, and Australia. Many of the natives who have come in contact with the agents of the Dutch East India Company have been nominally converted to Christianity. Its resources have not been sufficiently developed by the East India Company, but are likely eventually to prove a valuable source of profit to the Dutch. A cluster of small islands, called Ceram Lant, lies off the east end of Ceram.

CERATION (κεράτιον), the name given by the ancient Greeks to the small seed of the ceratonia (carob), used by the Arabian physicians as a weight for medicines. It was the same as the Latin *siliqua*.

CERATONIA, a genus of *Leguminosæ*, including only one species, *C. Siliqua*, the carob or locust-tree, a native of the shores of the Mediterranean. The pod contains a sweet pulp, on which it is supposed that St John the Baptist fed in the wilderness, when it is said his food was *locusts* and wild honey. It is true, however, that the Arabs and other tribes eat also the insect *locust*.

CERBERA, a genus of Apocineæ, the seeds of which—especially of *C. Tanghin*, and *C. Manghas* of Madagascar and India—are deadly poisons, and were once used in the former country as a sort of ordeal in criminal cases.

CERBERUS, in *Grecian Mythology*, a three-headed dog, born of Typhon and Echidna, and set to guard the entrance to Hades. He fawned upon those who entered, but devoured all who attempted to go back. He was, however, vanquished by Hercules, and dragged up to the light of day; when, in struggling, the foam that dropped from his mouth produced the poisonous herb called *aconite* or *wolf's bane*. Some have supposed that Cerberus is the symbol of the earth, or of all-devouring time; and that his three mouths represent the present, past, and future. The victory of Hercules over this monster denotes the conquest which that hero acquired over his passions. Bryant supposes that Cerberus was the name of a place, and that it signified the temple of the sun; deriving it from *Kir Abor, the place of light*. This temple was called also *Tor-Caph-El*, which was changed to τρικέφαλος; and hence Cerberus was supposed to have had three heads.

CERDONIANS, ancient heretics who maintained most of the errors of Simon Magus, Saturninus, and the Manicheans. Their leader Cerdo, a Syrian of the second century, went to Rome and there abjured his errors; but he was afterwards convicted of persisting in them, and cast out of the church. Cerdo maintained the existence of two first causes of all things, the one good and the other evil; and also an intermediate deity, who was the Creator of the world, and the God and the Lawgiver of the Jews. The first, whom he called *unknown*, was the Father of Jesus Christ, who, he taught, was incarnate only in appearance, and did not actually suffer death; with many other errors, in which he was succeeded by his disciple Marcion. (Reid's edition of Mosheim's *Eccles. Hist.*)

CEREALIA, in *Antiquity*, a festival of Ceres, instituted by Triptolemus, son of Celeus king of Eleusis, in gratitude for having been instructed by Ceres in agriculture and the art of making bread. The *cerealia* passed from the Greeks to the Romans, who celebrated them with games in the Circus Maximus, commencing generally on the ides or 13th of April, or as some suppose on the 7th. The spectators always appeared in white; and the wanderings of Ceres in search of Proserpine were represented by women in white robes, and holding lighted torches in their hands.

Cerealia (from the goddess *Ceres*), the esculent seeds of the grasses, or those which produce corn.

CEREBELLUM, the hinder and lower part of the brain. See Anatomy.

CEREBRUM, the brain. See Anatomy.

CEREMONIAL (*ceremoniale*), a ritual, or book containing the prescribed rules relating to the rites and ceremonies of the Romish Church.

Ceremonial is particularly applied to the forms and rites of the Jewish religion; as the *ceremonial law*, in contradistinction to the moral and the judicial law.

CEREMONY, external form of religion; outward forms of state; the forms prescribed for the purpose of civility or of magnificence, as in the levees of sovereigns, the reception of ambassadors, &c.

Ceremonies, Master of the, an officer first appointed by James I. to superintend the reception of ambassadors and strangers of rank.

CERES (called Demeter by the Greeks), the goddess of corn and harvests, and the protectress of agriculture. She was the daughter of Saturn and Rhea, and the mother of Proserpine by Jupiter. Enna in Sicily was regarded as the favourite retreat of the goddess—a legend that has reference to the fruitfulness of that island. When Proserpine was gathering flowers in the fields of Enna, Pluto carried her away; and Ceres, disconsolate at the loss of her child, resolved to discover the place of her concealment. Lighting her torch at the fires of Etna, she set forth in a chariot drawn by dragons. The search of Ceres long proved fruitless; but having at length obtained the information she desired, she immediately flew to heaven, and demanded the restitution of her daughter. Jupiter at last consented, provided that Proserpine had not partaken of food in the realms of Pluto. The unwelcome truth that Proserpine had eaten the seeds of a pomegranate was revealed by Ascalaphus, who for his pains was metamorphosed into an owl. Jupiter, moved at the overwhelming grief of Ceres, granted that Proserpine should pass only half of the year with her husband, and the remainder in the upper world. This legend obviously has reference to the seed-corn, which remains in the ground part of the year; and the return of Proserpine to her mother is the springing of the corn. As the cultivation of the earth had been neglected during the time that Ceres was wandering in quest of her daughter, the soil became barren; and in order to repair the loss occasioned by her absence, the goddess went to Attica, and there instructed Triptolemus of Eleusis in the science of agriculture. By her desire Triptolemus travelled over the earth and disseminated among men the knowledge he had received. Among the fables connected with the invention and extension of agriculture, is the story that by Iasion, who introduced agriculture into Crete, Ceres became the mother of Plutus the god of riches. The appellation of Demeter, by which she was known among the Greeks, appears to be a compound of γῆ and μήτηρ, equivalent to "mother earth." Her worship is said to have been introduced from Egypt into Greece by Erechtheus; and by some she is identified with the Egyptian Isis. In Greece her festivals were called *Thesmophoria* and *Eleusinia;* those at Rome, *Cerealia*. Ceres was greatly honoured by the Romans. Her festivals were annually celebrated by matrons, holding burning torches in their hands; and whoever ventured to appear without previous initiation was punished with death.

The adventures of Ceres during her search for Proserpine were numerous. By Neptune she became the mother of the horse Arion, and was so shocked at the monstrous birth that she withdrew from the sight of men. She was discovered in Arcadia by Pan, and induced to return to Sicily, where she was honoured with a statue veiled in black, with the head of a horse, and holding in one hand a dove, in the other a dolphin. The ram was sacrificed to Ceres, and also the sow, as being destructive to crops.

Ceres is usually represented as a majestic young woman, with the same matronly appearance as Juno, but of milder aspect, her eyes less full, the forehead lower, and instead of the high diadem, her head is adorned with a garland of ears of corn, or bound with a simple fillet. In her hand there appears a lighted torch, and sometimes a sickle, a cornucopia, a wreath, or a poppy, which was sacred to her. Sometimes she appears seated on an ox, carrying a basket on her arm, and in her hand a hoe. She is also represented riding in a chariot drawn by winged dragons.

By the poets, *Ceres* is used metaphorically for corn and bread, as *Bacchus* is used to signify wine. See Eleusinia.

Ceres, the name of a small planet between the orbits of Mars and Jupiter. It was discovered by Piazzi at Palermo in 1801. See Astronomy.

CERET, a pleasantly situated town of France, capital of an arrondissement of the same name, department of Pyrénées Orientales, 15 miles S.S.W. of Perpignan. Pop. (1851) 3575. Here, in 1660, the plenipotentiaries of France and Spain met to fix the limits between these two kingdoms.

CERIGNOLA, a well built episcopal city of Naples, province of Capitanata, situated on an eminence commanding an extensive view of the surrounding country, 23 miles S.E. of Foggia. It is divided into an old and new town, and has a college, several convents, hospital, &c., and some trade in cotton and fruits. It is celebrated for the victory gained here in 1503 by Gonsalvo de Cordova over the French forces under the command of the Duc de Nemours. Pop. (including the dependent village of Tressanti) 10,300.

CERIGO. See Cythera, and Ionian Islands.

CERINTHIANS, an ancient heretical sect, so called from Cerinthus their founder, who lived at the extreme close of the apostolic age, and is said to have been contemporary with the apostle John at Ephesus. In his opinions he seems to have combined the peculiarities of Gnosticism with the maintenance of extreme Judaism, the former element exclusively being combated by Irenæus, the latter by Caius, Dionysius, and Epiphanius. Judging from the statements of his adversaries, the doctrines which he held most prominently seem to have been the following, viz. the existence of different orders of angels in the *pleroma*, the lowest of whom only come in contact with the world of matter; the creation of the world by those angels under the control of a superior being who is yet infinitely removed in nature and intelligence from the deity; the distinction

of the man Jesus and the Christ or Logos in the person of the Saviour, the former alone being born and crucified, the latter descending on him at his baptism and ascending again at his apprehension by the Jews; and lastly, although this seems to contradict the whole tendency of his other opinions, the reign of Jesus and his attendant Logos on the earth during a millennium of sensuous enjoyment. It is probable the Gospel of John was written specially to counteract the growth of Cerinthian doctrine.

CERIUM, a grayish-white metal, first discovered in 1803 by Hisinger and Berzelius in a very rare Swedish mineral called cerite. See CHEMISTRY.

CERNE ABBAS, a market-town and parish of England, county of Dorset, on the river Cerne, an affluent of the Frome, seven miles north of Dorchester. An abbey was founded here in 987, of which some remains still exist. On Trendle Hill, N.W. of the town, is a colossal figure of a man with a club, 180 feet high, cut in the chalk. Pop. of parish (1851) 1343, chiefly employed in the manufacture of leather, gloves, and parchment.

CEROMA, in *Antiquity*, a mixture of oil and wax, with which wrestlers in the public games and bathers were anointed; likewise used for the *elæothesium* or place where this was done, as also in later times for the *palæstra* or wrestling ring itself.

CEROXYLON ANDICOLA, the only genus in this family of palms, remarkable for the large quantity of wax, mixed with two-thirds of resin, that flows from its bark, and invests its stem with a thick coating. This is collected, and with one-third of tallow is manufactured into candles. The plant attains the enormous height of 180 feet. It is found on the mountain chain separating the Rio Madalena from the Rio Cauca, in Lat. 4. 35. N. Unlike other palms, it only flourishes where the air is cooled by the vicinity of perennial snow. Its range is limited to about 20 square leagues. It is well named by the Spaniards *Palma de Cera*.

CERRETO, an agreeable and well-built town of Naples, province of Terra di Lavoro, 21 miles N.W. of Benevento. It has a fine cathedral, collegiate church, seminary, and manufactures of coarse woollens. Pop. 6000.

CERTALDO, a market-town of Tuscany, on the Elsa, province and 18 miles S.W. of Florence, celebrated as the birthplace of Boccaccio, whose house is still preserved.

CERTIORARI, in *Law*, a writ which issues out of the chancery, directed to an inferior court, to call up the records of a cause there depending, in order that justice may be done. It is not only used out of the court of chancery, but likewise out of the king's bench, in which last-mentioned court it lies where the king would be certified of a record.

CERUMEN, the waxy matter secreted by the ear. It consists of albumen, an oily matter, a colouring matter, soda, and phosphate of lime.

CERUSE (Lat. *cerussa*), or WHITE-LEAD, a carbonate of lead produced by exposing that metal in thin sheets to the vapour of acetic acid. Ceruse sometimes occurs native as white-lead spar. It is the basis of the ordinary white oil paint, and in its semi-solid form is used as a cement for stone, &c.

CERVANTES, SAAVEDRA MIGUEL DE, the inimitable author of Don Quixote, was born at Alcala de Henares, New Castile, Oct. 9, 1547. He was descended from a noble family, and was the youngest son of Rodrigo di Cervantes and Leonora de Cortinas. From his earliest years he showed an insatiable love of reading, which induced his father to send him to Madrid, that he might receive his education under Juan Lopez de Hoyos, and be fitted for the profession of theology, medicine, or law. The poetical bent of his genius, however, gradually withdrew his attention from these severer studies, and led him at last to devote his whole time to the composition of verses. His first attempt of this kind was an elegy on the death of Queen

Isabella, and was speedily followed by a pastoral entitled *Filena*, several sonnets, romances, and other poems. The apathy with which his countrymen, even his friends, received these productions, roused Cervantes to seek a more favourable field for the display of his talents abroad. In 1569 he set out for Rome, where he became valet to Cardinal Aquaviva, to whom he had been introduced at Madrid. In the following year he quitted the cardinal's service, and joined the expedition fitted out under Marco Antonio Colonna to succour the Cyprians against the invasion of Selim II. He was present at the action in the Gulf of Lepanto, and conducted himself with great bravery, but had the misfortune to receive a severe wound in his left hand, which deprived him of the use of it for life. He was carried in a Spanish ship to the hospital at Messina, and when dismissed immediately rejoined the troops at Naples, who were preparing to march on an expedition against Tunis. During this period he assiduously improved his knowledge of Italian, and had an opportunity of visiting the most celebrated cities of Italy. In 1575 he set out with his brother for Madrid in a Spanish galley called El Sol (the Sun), which had scarcely set sail when they encountered a squadron of Algerian pirates, and were taken prisoners and carried to Algiers, where they remained for four years. Cervantes made many vigorous efforts for the release of himself and his companions, and one of these was so nearly successful that having avowed himself the author of the scheme he was adjudged to death. The admiration, however, which his master entertained for his conduct procured the transmutation of the sentence, and he was soon after transferred as a slave to the service of the Dey. In this situation his enterprising mind conceived a scheme of insurrection, and though the plot was discovered the feeling of respect and even awe with which he was regarded secured him from any ignominious treatment. After many unsuccessful attempts on the part of the Spaniards to relieve the captives, Cervantes and his companions were redeemed in 1580 through the intervention of the Trinitarian Fathers Juan Gil and Antonio de la Bella, who paid down 500 gold ducats for his release. But his misfortunes had not yet cooled down his military ardour; for on his return to Spain he again resumed his arms, and went in three successive expeditions to the Azores. On his return he composed his pastoral romance of *Galatea*, in honour, it is said, of a certain Doña Catalina de Palacios Salazar, whom he shortly after married. From this period he was for ten years employed in writing plays for the Spanish stage, but of the thirty which he wrote only two have survived, viz. *Los Tratos de Argel* (Life in Algiers) and *La Numancia*. For some time he lived at Seville, where he held the office of assistant purveyor to the Indian fleet, and probably wrote the first part of *Don Quixote*, which, however, was not printed till 1605. Eight years after appeared the *Novelas Exemplares*, consisting partly of serious partly of comic pieces, in which *examples* are given of virtues to be imitated and vices to be shunned. This was followed by the *Viage el Parnasso* (Journey to Parnassus), a satirical piece written in imitation of a similar work by Cæsar Caporale, an Italian poet of the sixteenth century. In 1615 he published the continuation of *Don Quixote*, which immediately supplanted a spurious continuation written by Fernandos de Arellaneda a short while before, and placed the author still higher in popular estimation than before. The work was read by his countrymen with the utmost avidity, and immediately translated into all the European languages. The last work which Cervantes wrote was entitled *Trabajos de Persiles y Sigismunda*, a grave romance, written after the Theagenes and Chariclea of Heliodorus. At the end of the preface to this book he alludes with touching playfulness to the dropsy which was slowly consuming his life,—"the thirst attending which," he says, "all the water of the ocean, though it were

not salt, would not suffice to quench." Notwithstanding the agonies which he suffered from this constantly increasing malady, he continued writing and talking in his characteristically humorous strain, till his death on the 23d April 1616—the same day which deprived the world of Shakspeare. For a critical estimate of Cervantes' writings, see ROMANCE.

CERVERA, a town of Catalonia, Spain, 57 miles N.W. from Barcelona. It stands on an eminence, is fortified, and possesses the remains of an ancient castle. It has a fine Gothic church, and several convents. Its university (originally transferred from Lerida by Philip V.) has recently been removed to Barcelona. The inhabitants are almost exclusively engaged in agriculture. Pop. 4500.

CERVIA, an episcopal town of the Papal States, on the Adriatic, delegation and 12 miles S.E. of Ravenna. In the vicinity are extensive salt-works. Pop. 3000.

CESARE, one of the modes of the second figure of syllogisms, the minor proposition of which is a universal affirmative, and the others universal negatives; thus,

cE No immoral books ought to be read;
sA But every obscene book is immoral;
rE Therefore no obscene books ought to be read.

CESARI, GUISEPPE, called IL CAVALIERE D'ARPINO, an Italian painter much encouraged at Rome and munificently rewarded, while A. Caracci was so ill requited for his finest works. Cesari is stigmatized by Lanzi as not less the corrupter of taste in painting than Marino was in poetry. There was spirit in Cesari's heads of men and horses, and his frescoes in the capitol are well coloured; but he drew the human form ill. His perspective is faulty, his extremities monotonous, and his chiaroscuro defective. He died in 1640, at the age of 72.

CESAROTTI, MELCHIORRE, an Italian poet, born at Padua in 1730, of a noble but reduced family. He early showed a very decided inclination for literary pursuits, in which he made such progress at the college of his native city, that he was appointed to the chair of rhetoric at a period of life when others were yet attending the lectures. The first fruits of his studies were Italian translations of the Prometheus of Æschylus, and three tragedies of Voltaire, by the merit of which, and the reputation he had acquired for learning and persevering application, he procured successively the appointment of tutor to the children of Grimani, a nobleman of Venice, and the professorship of Greek and Hebrew in the university of Padua. Cesarotti had held this situation for nearly thirty years at the date of the first French invasion of Italy. This poet did not, like Alfieri, scorn the pecuniary favours of the republican government. He published several political tracts and essays by their order; and when the general of the invading army assumed the title of King of Italy, Cesarotti received two pensions of considerable amount, and was made a knight of the iron crown. He continued to reside alternately at Padua and his country house of Selvaggiano, chiefly occupied with the composition of laudatory poems in return for the favours he had received, and with the superintendence of a complete edition of his works. While thus engaged he died suddenly on the 3d November 1808.

Though held by Sismondi to be the first in point of celebrity of the modern Italian poets, Cesarotti is better known as a translator than as an original author. The Italians have always been distinguished for the elegance and spirit of their translations from the classics; the Lucretius of Marchetti, the Æneid of Annibale Caro, and Anguillara's free version of the Metamorphoses of Ovid, have deservedly exalted their reputation to the utmost height in this department of literature. Anguillara's translation of Homer, however, had been less popular and successful than his Metamorphoses, and there still remained room in Italy for a translation of the prince of poets. The work of Cesarotti, however, is far from being literal; he has modernized and accommodated the Iliad to the prevailing taste of the age; he has abridged it in some places, and added to it in others, according to his taste or fancy; and he has often been reproached with having given to the Greek bard the style and language of his favourite Ossian. In the late edition of the works of Cesarotti, the poetical version is followed by a literal prose one, accompanied with critical notes and dissertations, partly translated from Pope and Dacier.

Cesarotti acquired more fame by his version of Ossian than by that of Homer. He has completely preserved the spirit of the supposed bard of Morven, and, at the same time, has given us that harmony of versification which we desiderate in the work of Macpherson. The Italian Ossian was first published at Padua in 1763, 2 vols. 8vo, at the expense of Mr Sackville, an English traveller with whom Cesarotti had contracted a friendship. This edition was necessarily incomplete, as the translation of Macpherson at that time was so also; but the whole poems were printed at the same place about ten years afterwards, in 4 vols. small 8vo. Their appearance attracted much attention in Italy, and raised up many imitators of the Ossianic style.

Cesarotti also produced a number of valuable prose works. The *Course of Greek Literature* was his chief undertaking; but the plan on which he commenced was too vast to be completed. His essays on the *Sources of the Pleasure derived from Tragedy*, and on the *Origin and Progress of the Poetic Art*, are distinguished by elegant and ingenious criticism; while his treatises *Sulla Filosofia delle Lingue, et Sulla Filosofia de Gusto* (the last of which is principally intended as an apology for the peculiarities of his own style), show considerable acuteness and strength of understanding. In 1797 an Academy of Sciences and Belles Lettres had been established at Padua, of which Cesarotti was nominated perpetual secretary. Almost all the prose works of Cesarotti are distinguished by extensive erudition and a philosophical spirit, while his style is for the most part lively and forcible. But the Italian prose of the eighteeenth century was very different from that written by Giovanni della Casa, Machiavel, and their contemporaries in the sixteenth; and those critics who have deplored the recent innovations on the ancient purity of the Tuscan tongue, chiefly attribute to Cesarotti the introduction of those Gallicisms and new modes of expression which have so greatly corrupted the language of the golden age of Leo.

All the works of Cesarotti above mentioned, including several volumes of correspondence, have been published in a complete edition, which was commenced at Padua in the year 1800, under the author's own direction. It has been continued since his death by Guiseppe Barbieri, who was his successor in the chair of Greek and Hebrew at Padua, and who has also published Memoirs of the Life and Writings of his deceased friend, printed at Padua, 1810, 8vo. (J. C. D.)

CESENA, a neat and pleasantly situated episcopal town of the Papal States, on the Sario, in the legation and 12 miles S.E. of Forli. The *Palazzo Pubblico* is a fine building, ornamented with a statue of Pius VI., who was a native of this town, as was also his successor Pius VII. The Capuchin church contains a fine painting by Guercino. The library, the principal object of interest, was founded by Malatesta in 1452, and is rich in MSS. In the vicinity are extensive sulphur mines. Pop. 14,500.

CESSIO BONORUM, in the civil law, is the rendering up by an insolvent debtor of his property for the use of his creditors; and the term has hence come to be applied to that relaxation from the rigour of the law which the debtor obtains on making a surrender of his property. It has thus entered into the nomenclature of the modern systems derived from the civil law, with some variation of meaning. In France the *Cession de Biens* is a step in the bankruptcy system. (*Code de Commerce*, liv. iii. tit. ii.) In Scotland the process which corresponds with the English insolvent debtors' system, and gives a modified relief to bankrupts not connected with commerce, is called *Cessio Bonorum*. It is regulated by statute (6th and 7th Will. IV., cap. 56). See, for farther information on the modern application of the law of cessio, the two heads BANKRUPTCY and INSOLVENCY. The relaxation of the Roman law, which relieved

the debtor from the cruel operation of the older system, on his making a general cession of his goods, is generally attributed to Julius Cæsar. The operation of the system and the writings of the jurists did much to illustrate for modern adoption and practice the principles on which a sound insolvent debtors' system should be founded. See some curious notices in Heineccius ad Pan., lib. xlii. tit. 2; and the 3d title of the forty-second book of the Pandects.

CESTUS (from κεστός, stitched, embroidered), the zone or girdle of Venus, to which Homer ascribes the power of captivating the affections. It was the marriage-girdle of the Greeks and Romans; among whom the ceremony of unloosing the cestus of the bride on the nuptial night was performed by the husband of the bride. The word is sometimes written *cæstus*.

CESTUS also denoted a boxer's glove, as described under CÆSTUS, and BOXING.

CETTE, a seaport in the south of France, department of Hérault. N. Lat. 43. 25 ; E. Long. 3. 40. It stands on a peninsula formed by the Mediterranean and the lake of Thau, which are connected by a canal passing through the town. It possesses a deep and commodious harbour, a spacious dock, and handsome quays. The entrance to the harbour is defended by two strong forts, that of St Pierre on the left side, and that of St Louis on the right. Cette has tribunals of commerce and of primary instance, a public library, and a college, besides extensive salt-works and ship-building yards. It communicates by canal with Lyons and Bordeaux, and by rail with Marseilles, Nîmes, and Avignon. From its vicinity to the great wine districts of the south of France it has an important trade, and exports largely wine, brandy, sugar, glass, wine-casks, &c. The imports consist of corn, wool, cotton, hemp, timber, and iron. The cod and oyster fisheries off the coast engage a large number of hands. In 1853 the number of vessels that entered and cleared the harbour amounted to more than 4000. Pop. about 20,000.

Cetus || Ceylon.

CETUS, the Whale, a large constellation of the southern hemisphere, containing 97 stars.

CEUTA, or SEPTA, a Spanish fortress on the coast of Fez, Africa, on a peninsula opposite Gibraltar. N. Lat. 35. 56.; W. Long. 5. 18. It is built on the Monte del Hacho (the ancient *Abyla*, one of the pillars of Hercules), and six smaller hills that run along the coast. The town is well built, and is chiefly important as a military and convict station. It contains a cathedral, the bishop of which is suffragan to the archbishop of Seville, several religious houses and a hospital. It has a small harbour, and imports provisions and military stores from Spain. Pop. 9237, exclusive of the garrison, which may be estimated at 5000 men. Ceuta was taken from the Moors by John I., king of Portugal, in 1415, and passed into the hands of the Spaniards on the subjugation of Portugal by Philip II. in 1580. It has been several times unsuccessfully besieged by the Africans.

CEVA, the ancient *Ceba*, a town in the kingdom of Sardinia, province and 10 miles east of Mondovi, at the confluence of the Cevetta with the Tanaro. It was formerly fortified; and the rock, at the foot of which lies the town, was surmounted by a citadel. Pop. 4000, chiefly employed in the manufacture of silk, and in iron works. It is noted for its cheeses, in which it has a considerable trade.

CEVENNES, a mountain-chain in the south of France, dividing the valleys of the Lower Saône and Rhone from those of the Loire and Garonne. The highest peak is Mount Mezen, in the department of Ardèche (5970 feet). The principal formation is granite; and beds of trachyte and lava in many quarters give token of former volcanic action. The lower slopes are cultivated with great industry; the more elevated regions are pastoral; and the summits are generally clothed with forests of chestnut and pine. The Cevennes were made the retreats of the Huguenots in the beginning of the eighteenth century.

CEYLON,

AN island in the Indian Ocean, situated at the southern extremity of the Coromandel coast, from which it is separated by the Gulf of Manaar. It lies between N. Lat. 5. 54. and 9. 50., and E. Long. 79. 50. and 82. 10. Its length is 270 miles, and its greatest breadth 145 miles. It is of an oval form, pointing north and south; its broadest part being at its southern extremity, where also is to be found the great mass of its high lands. It is distant from Cape Comorin, the southernmost point of the Indian Peninsula, about 175 miles.

Aspect of the country.

The N.W. coast of Ceylon is beset with numberless sandbanks, rocks, and shoals, and may be said to be almost connected with the continent of India by the island of Ramisseram and Adam's Bridge, a succession of bold rocks reaching almost across the gulf at its narrowest point. From its position and its geological character, Ceylon would appear to have been at an early period the southern extremity of the mainland, from which it has been doubtless separated by some great convulsion of nature. Between the island and the opposite coast there exist two open channels of varying depth and width, beset by rocks and shoals. One of these, the Manaar Passage, is only navigable by very small craft. The other, called the Paumben Passage, lying between Ramisseram and the mainland, has been deepened at considerable outlay, and is now used by vessels of 300 tons in passing from the Malabar to the Coromandel coast, and which were formerly compelled in doing so to make the circuit of the island.

The west and south coasts are uniformly low, fringed their entire length by cocoa-nut trees, which grow to the water's edge in great luxuriance, and give to the island a most picturesque appearance. Along these shores there are numerous inlets and backwaters of the sea, some of which are available as harbours for small native craft. The east coast from Point de Galle to Trincomalee is of an entirely opposite character, wanting the ample vegetation of the other, and being at the same time of a bold precipitous character. The largest ships may freely approach this side of the island, taking care to avoid a few dangerous rocks, whose localities are, however, well known to navigators.

Seen from a distance at sea, this "utmost Indian isle" of the old geographers wears a truly beautiful appearance. The remarkable elevation known as "Adam's Peak," the most prominent, though not the loftiest of the hilly ranges of the interior, towering like a mountain-monarch amongst an assemblage of picturesque hills, is a sure land-mark for the weary navigator, when as yet the Colombo lighthouse is hidden from sight amidst the green groves of palms that seem to be springing from the waters of the ocean.

The low coast-line of country encircles the mountain-zone of the interior on the east, south, and west, for a varying distance of from 30 to 80 miles; but on the north the whole breadth of the island from Calpentyn to Batticaloa is one vast sandy plain, teeming with low jungle, swamps, and sterile deserts.

The great central mountain range rises in most places with considerable abruptness. Its general direction is from north to south, but is nevertheless much broken up, sending off spurs of great size and extent in many directions. These ranges are clothed with verdure to their very summits;

and along their base, stretching far into the beautiful fertile valleys which intersect them in every direction, are vast forests of gigantic trees now fast disappearing before the planter's axe.

For a long period Adam's Peak was universally supposed to be the loftiest mountain in Ceylon, but actual survey makes it but 7420 feet above the sea-level. This elevation is chiefly remarkable as the resort of pilgrims from all parts of the East, it being the belief amongst Buddhists and Mussulmans that Adam on leaving Paradise rested upon one foot on this summit. To this day the print of a human foot on the rock, $5\frac{1}{4}$ feet in length by $2\frac{1}{8}$ in breadth, is shown, carefully protected from the weather and guarded by priests who have a shrine on this lofty peak. Pedrotallagalla, a bold abrupt rock between the valleys of Maturatta and Newere Ellia, is the loftiest elevation in the island, being 8280 feet high. There are two other mountain peaks of great height, being respectively 7810 feet and 7720 feet.

The elevation of the greater portion of the fertile valleys and hill-sides of the interior, at present teeming with extensive coffee plantations, ranges between 2000 and 4000 feet. The plain of Newere Ellia, the sanatarium of the island, is at an elevation of 6210 feet, and possesses many of the attributes of an alpine country. The town of Kandy, in the central province, and formerly the capital of the ancient kings of that country, is situated 1678 feet above the sea-level.

Rivers. It might be expected that an island so completely within the influence of oceanic evaporation, and possessing an elevated table-land of considerable extent, should boast of some rivers of magnitude. This, however, is not the case. The rains which usher in each monsoon or change of season are indeed heavy, and during their fall swell the streams to torrents, the torrents to impetuous rivers. But when these cease, the water-courses fall back to their original state; the foaming streams are once more murmuring brooks, and but few of the rivers cannot be passed on horseback. The largest of the Ceylon streams, the Mahavilla-Ganga, has its source in the Pedrotallagalla mountain, whence it courses very tortuously through the Kotmalie valley to Pasbage; and thence winding to the south and west of Kandy, sweeps suddenly to the north, and finally falls into the wild and open country of Bintenne, through which it takes a course almost due north as far as Trincomalee, near which town it falls into the sea by two outlets after a course of about 200 miles. Like all the Ceylon rivers, this can only be passed with great difficulty during the rainy season, running as it does for 100 miles through a rocky and precipitous country. It is seldom wider than the Thames at Richmond, and generally of much less width. Surveys have shown that, at some outlay for blasting rocks, this river might be made navigable for a distance of 80 or 90 miles from Trincomalee. At Peradinea, $4\frac{1}{2}$ miles from Kandy, it is crossed by a beautiful bridge of satin-wood of a single span of 205 feet, erected by Colonel Fraser on the wedge principle.

The Kalany Ganga has its rise at the base of Adam's Peak, whence running almost due west as far as Ruanwella it takes its way more southerly to Colombo, where on its northern outskirt it falls into the ocean across a wide sandbar. This stream is navigable for about 40 miles by means of flat-bottomed boats. The Kalu Ganga and the Wallawe Ganga flow from the eastern vicinity of Adam's Peak through the district of Saffragam to the sea, the former south-westerly, the latter south-easterly: both are navigable for some distance by country boats. The Maha Oya or "great stream" rises in the mountains to the southwards of the Hanguranketty valley, and after a winding course of 70 miles in a west, north-west, and south-westerly direction, falls into the sea at Kaymel, dividing the districts of Putlam and Negombo. There are many other streams within the interior tributaries of the above, but unless during the heavy rains they are of no magnitude, and are in no instance navigable.

Lakes and canals. There are some lakes of considerable extent and of great beauty. Those of natural formation are situated at Colombo and Negombo. The former is but a few miles in circumference, and was deepened and extended by the Dutch with a view to the defence of the town against the natives. In these days it is more valued for its picturesque beauty than its defensive qualities. The lake of Negombo is a fine sheet of water of great extent, and is connected with that of Colombo by means of canals, partly natural and partly artificial. The Dutch whilst in possession of the island did much to improve its water communication, and this was one of their most useful works. On the west coast as far as Calpentyn, on the N.W. shores, and also along the eastern coast, there are numerous and extensive salt-water lakes or lagunes, more or less connected by means of canals and streams.

Artificial lakes appear to have been constructed by the Singhalese monarchs at very remote periods, for the purpose of irrigation. By damming across the mouths of valleys, the waters which in the rainy season would have flowed through them into the low country and have been lost in the ocean, were by these means saved until required during the time of drought, when they were allowed to flow through proper channels of solid masonry to the desired localities. The remains of some of these lakes, ruined as most of them are, attest the industry of the dense population which once filled regions that are now the abode of the buffalo and the cheetah. One of those, the lake of Minery, although constructed fifteen centuries ago, is still in excellent preservation, and serves to irrigate a large district between Trincomalee and Kandy. It is 20 miles in circumference, and has an embankment 60 feet wide at the top. Others, now in a state of dilapidation, were once of enormous extent and solidity. One appears to have had a wall of masonry 12 miles long by 100 feet thick, and in its dry bed are to be seen as many as a dozen villages, around which rice fields grow and bananas wave to the breeze that once swept over a little inland sea. The Kandy lake is built up in a similar way; and while it ministers to the convenience and salubrity of that town, adds not less to its beauty. Surrounded on every side by wooded hills, and skirted by an excellent carriage road, which is sheltered from the sun by palm trees, it offers to the visitor one of the most delightful tropical drives that can be met with.

Harbours. Although Ceylon is possessed of two excellent harbours, one of them many miles in extent and easy of entrance, they are nevertheless of little importance, since the entire European shipping business is conducted at Colombo, the English seat of government, which possesses but an open roadstead. The harbour of Trincomalee is perhaps one of the finest in the world; but, situated on the north-eastern extremity of the island out of the track of ships and far removed from the productive districts, it is only employed as an admiralty station. The harbour of Galle, though much smaller, is still capacious, but difficult of access, and is open to the same objection of being too remote for a port of shipment, except of such few products as are grown in its neighbourhood. Open, however, as is the Colombo roadstead, it affords a safe anchorage for ships during all months of the year, even in June and October, when communication with the shore is difficult if not dangerous.

Roads. The policy of the Singhalese rulers of the island having been directed to the exclusion of strangers from their country amongst the hills, they never attempted to construct roads, but rather aimed at rendering travelling a matter of impossibility to all but natives: tortuous foot-tracks were still the only means that existed of passing from one district to the other throughout the wild regions of the interior, when

the British assumed the sovereignty of the Kandian country in 1815. In the low country of the maritime province, neither the Portuguese nor the Dutch had paid much attention to roads; preferring to trust to their canals for the transport of goods, and not caring to explore a country that seemed to offer nothing but hostility to them. The necessity of opening up the interior was first seen in a military point of view; and the construction of the road between Colombo and Kandy, 72 miles in length, carried over swamps, along the edges of precipices, and up the steep sides of mountain passes, attested at once the importance of the work, and the skill and industry of the constructors. It is as wide, and in most places as good, as any European road; whilst at distances of 8 miles, rest-houses and stabling for travellers were erected at the public expense, and are only now neglected because the daily mail-coach renders them no longer necessary. An equally good road connects Galle with Colombo, and the latter with Negombo.

The rapid extension of coffee planting in the Kandian country, since the year 1841 has led to large and constant outlay upon the construction of new roads, suitable for the transport of crops from the planting districts to Colombo.

Previous to 1841, the whole extent of carriage roads throughout the island was 1572 miles, one-third of which lay along the sea-coast, and consisted of little more than wheel-tracks over sandy plains. During the five years ending with 1846, there were nearly 800 miles of new road opened through a great variety of country, and differing in their costliness from an outlay of L.20 a mile in flat country, to L.500 a mile in some of the most elevated districts, where the blasting of rocks and building up the sides of precipices form heavy items in the outlay. The sums expended on roads during those five years amounted to a total of L.201,621, the tolls collected for the same period having been L.107,066.

From that time until the passing of the road ordinance in 1848, little more was done than to keep the existing roads in repair. By the working of the new law, which called upon every able-bodied male adult to labour for six days in each year upon the roads in his district, a great deal has been done towards opening up the interior; and there are now upwards of 3000 miles of carriage road in the island, of which 600 miles are principal roads, 1700 are second class, and 700 third class roads. The outlay upon the roadways of the island in 1852 amounted to L.54,472, of which labour to the value of L.17,951 was contributed under the road ordinance, and L.36,521 was paid out of the public treasury. The latter was for skilled labour, a large force of Malabar artizans being kept up under a sort of military discipline in various parts of the country.

Seasons, climate, &c.

The seasons in Ceylon differ very slightly from those prevailing along the coasts of the Indian peninsula. The two distinctive monsoons of the year are called, from the winds which accompany them, the south-west and the north-east. The former is very regular in its approach, and may be looked for along the S.W. coast between the 10th and 20th of May. It is ushered in by heavy banks of clouds to seaward, and much lightning. Heavy squalls of wind and rain from the S. and S.W. usually prevail for three weeks, when the weather moderates, and smart showers continue to fall with more or less frequency until the beginning of August. The monsoon is then very pleasant until early in October, when the sea-breeze fails, and calms prevail until early in November. The N.E. monsoon visits this part of the island between the end of October and the middle of November less violently than the other, the rains being far more moderate, and seldom extending past December. To the north of the Kandian country the features of each monsoon are reversed; there the violence of the N.E. is greatest and first felt, whilst that of the S.W. monsoon is latest and least felt.

During the S.W. monsoon in Colombo, the temperature usually ranges about 83°, with seldom more than two or three degrees of variation during the 24 hours. In the N.E. monsoon, on the contrary, the thermometer ranges between 72° at day-break, and 87° at two P.M., which is the hottest time. At various altitudes, however, in the Kandian country, any temperature downwards to the freezing point may be attained early in the year. The *sanatarium* of Ceylon, Newere Ellia, during the cold season of January and February, shows a temperature of 31° in the morning; whilst the ordinary range upon the best coffee estates is between 56° and 80°. The quantity of rain which falls in some of the mountain districts of the interior in one month nearly equals the fall in England during an entire year—being 21 inches. During the dry season rain has been known not to fall for three months. The average annual fall of rain at Colombo is 85 inches. In the hills it often reaches 120 inches. The length of the day, owing to the proximity of the island to the equator, does not vary more than an hour at any season. Daylight may be reckoned as usually lasting from 6 A.M. until 6 P.M.

Diseases.

The salubrity of Ceylon greatly excels that of most parts of continental India. With ordinary care Europeans may pass many years in the island as free from disease as in any part of Europe. Natives attain to a great age, especially in the hilly districts, in the centre of which, at an elevation of 6000 feet is the sanatarium of the island, Newere Ellia, the favourite resort of Indian invalids.

The prevailing diseases of the country are cholera, dysentery, fever, and hepatic attacks. Elephantiasis, a disease attended by enormous swelling of the limbs, is peculiar to the natives, and of frequent occurrence. The first-named disease is mainly confined to natives and soldiers, the three following chiefly to Europeans. The only available returns of mortality showing the causes of death, are those of the English regiments doing duty in the island, tables which, looking to the reckless mode of living prevalent amongst soldiers, must not be taken as representing the average mortality amongst European residents. The following tabular statement of deaths at the central, western, southern, and north-eastern military stations of Ceylon, have been compiled from returns extending over a period of seventeen years:—

Annual Ratio of Mortality per 1000 *of mean strength.*

	Kandy.	Colombo.	Galle.	Trincomalee.
By fever	25·6	8·5	1·9	19·8
By diseases of stomach and bowels	17·9	21·5	7·8	39·7
Do. lungs	5·0	5·3	2·6	4·6
Do. liver	3·1	4·5	3·9	7·4
By cholera	·8	5·8	0·	14·1

Geology.

The geological constitution of Ceylon, equally with other circumstances, goes to show that at a remote period the island formed the southern point of the Indian peninsula. Detached from the continent at some early geological epoch, it would appear that, unlike other countries possessing similar constituents, it has not been subject to alternate submersions and upheavals; indeed, it may well be doubted if it has even once been covered with water since the time at which it first became dry land; nearly the whole of the soil, with the exception of the alluvial deposits and the sandy plains of the maritime provinces, having been formed from the decomposition of the gneiss rocks.

It is at the same time believed that the whole island is undergoing a gradual elevation; in proof of which geologists point to extensive strata of sea-shells and corallines underlying many fertile alluvial plains in the southern province at a considerable distance from the sea. In the northern, eastern, and southern districts of the island, numerous instances of post-tertiary formations may be met with in the shape of elevated terraces of shells and masses of coralline rocks, intimately blended with marine shells in every respect similar to the living specimens inhabiting the neighbouring waters. Large masses of this rock may be seen at an ele-

Ceylon.

vation of seven or eight feet above the ordinary sea-level and a mile or two distant from the beach; indeed a large portion of the peninsula of Jaffna is formed of these marine remains in various stages of solidification. On the east and southern coasts the hardest of these formations are quarried and employed in ordinary works of masonry, some of the best dwellings being formed of them.

The Ceylon series of rocks are few in number. The lowest and most common is gneiss, overlaid in many places in the interior by extensive beds of dolomitic limestone. This formation appears to be of great thickness; and when, as is not often the case, the under surface of the gneiss series is exposed, it is invariably found resting on granite. Veins of pure quartz and felspar of considerable extent have been frequently met with in the gneiss; whilst in the elevated lands of the interior in the Galle districts may be seen copious deposits of disintegrated felspar, or *kaolin*, commonly known as porcelain clay. At various elevations the gneiss may be found intersected by veins of trap rocks, upheaved whilst in a state of fusion subsequent to the consolidation of the former. In some localities on the sea shore these veins assume the character of pitch-stone porphyry highly impregnated with iron. Hornblende and primitive greenstone are found in the vicinity of Adam's Peak, and in the Pusilava district.

The substance known in Ceylon as *cabook*, and assimilating greatly to the *kunker* of the Indian peninsula, exists in vast quantities in many parts of the western province, and is quarried for building purposes.

Mineralogy.

As yet no traces of coal have been found, with the exception of a little anthracite; but looking to the position of the carboniferous deposits of northern India, lying as they do on the gneiss formation, it is not impossible that similar deposits may be here met with in like positions.

Specimens of tin, platina, copper, and black oxide of manganese from the southern province, have been placed in the museum of the Ceylon Asiatic Society. Quicksilver mines existed at one time in the vicinity of Colombo, and the Dutch are said to have exported the article to Europe. Plumbago is quarried to a great extent in the Caltura district of the southern province, and has for a series of years formed a considerable item in the exports of the island. It is almost entirely produced by natives, who, however, work the quarries in a very careless manner, mixing sand and stones with the mineral. It is found at depths varying from three to thirty feet, and generally exists in rich seams. In 1846 the shipments of this article amounted to 25,036 cwts., valued at L.3036. In 1851 they were 31,126 cwts., worth L.4756. Iron exists in vast quantities in the western, southern, and central provinces, of excellent quality, in many places cropping out at the surface in a state of great purity. The Singhalese have been accustomed to work the ore into tools and implements from the most remote times; and although the means they employ are rude, imperfect, and wasteful in the extreme, they nevertheless manufacture articles which are esteemed by them far above those imported from Europe. The rudely worked Singhalese iron is equal in temper to the finest Swedish metal, and English capital and skill are alone wanted to render the iron resources of the island equal in value to any other of its natural wealth.

Nitre and nitrate of lime are to be met with in many caves of the low country, whilst alum and sulphate of magnesia are known to exist, though in limited quantities. Natural deposits of common salt are found in many parts of the maritime provinces. It is also produced by artificial means in large quantities under the supervision of government, in whose hands its manufacture and sale form a monopoly which yields an annual revenue of considerable amount. In 1843 the sale of this article yielded L.36,492.

In the Saffragam district precious stones are met with in great abundance; also, though less commonly, in the Badulla and Newere Ellia districts. The most valuable are the ruby, the sapphire, the amethyst, the cats-eye, and the carbuncle, Emeralds are rarely met with in any purity; but the moonstone, cinnamon stones, and garnets, are found in great abundance and variety.

Soil.

The natural soils of Ceylon are composed of quartzose gravel, felspathic clay, and sand often of a pure white, blended with or overlaid by brown and red loams, resulting from the decay of vegetable matter, or the disintegration of the gneiss, hornblende, and cabook formations. The whole of the great northern extremity of the island consists of a sandy and calcareous admixture made to yield productive crops of grain, tobacco, cotton, and vegetables by the careful industry of the Tamul population, who spare no pains in irrigating and manuring their lands. Between the northern districts and the elevated mountain ranges which overlook the Bintenne and Ouvah countries, are extensive plains of alluvial soil washed down from the table-lands above, and where once a teeming population produced large quantities of grain. The remains of ancient works of irrigation bear testimony to the bygone agriculture of these extensive regions now covered by pestilential swamps or dense jungle.

The general character of the soil in the maritime provinces to the east, south, and west, is sandy. Large tracts of quartzose sand spread along the whole line of sea-coast, some of which, of a pure white, and very deficient in vegetable matter, is admirably adapted to the growth of the cinnamon plant. In the light sandy districts, where the soil is perfectly free, and contains a portion of vegetable and mineral loam, the cocoa-nut palm flourishes in great luxuriance. This is the case along the entire coast line from Calpentyn to Point de Galle, and further eastward and northward to Matura, stretching to a distance inland, varying from 100 yards to 3 miles. From this light sandy belt as far as the mountain-zone of the Kandian country the land is mainly composed of low hilly undulations of sandstone and ferruginous clay, incapable of almost any cultivation, but intersected in every direction with extensive valleys and wide plains of a more generous soil, not highly fertile, but still capable, with a little industry, of yielding ample crops of rice.

The soil of the central province, although frequently containing great quantities of quartzose sand and ferruginous clay is, in many of the more elevated districts, of a fine loamy character. Sand sufficiently vegetable and light for rice culture may be seen at all elevations in the hill districts; but the fine chocolate and brown loams overlaying gneiss or limestone formations, so admirably adapted for coffee cultivation, are only to be found on the steep sides or along the base of mountain ranges at an elevation varying from 2000 to 4000 feet. Such land well timbered, contains in its elements the decomposed particles of the rocks above, blended with the decayed vegetable matter of forests that have for centuries scattered beneath them the germs of fertility. The quantity of really rich coffee land in these districts is but small as compared with the extent of country, vast tracts of open valleys consisting of an indifferent yellow tenacious soil interposed with many low ranges of quartz rock.

Botany.

The characteristics of the low-growing plants of Ceylon approach as nearly to those of the coasts of southern India as do the geological features of the island to those of the Malabar and Coromandel districts. The *Rhizophoreæ* are numerous along the low muddy shores of salt lakes and stagnant pools. The acacias are equally abundant; and the list comprises *Ægiceras fragrans*, *Epithinia malayana*, *Thesepesia populnea*, *Feronia elephantum*, *Salvadora persica* (the true mustard tree of Scripture), *Eugenia bracteata*, *Eleodendron Roxburghii*, *Cassia fistula*, *Cassia Roxburghii*, &c. &c. The herbaceous plants of the low country belong mostly to the natural orders *Compositæ*, *Leguminosæ*, *Rubiaceæ*, *Scrophularineæ*, *Euphorbiaceæ*, *and Rabiaceæ*

Ceylon.

Leaving the plains of the maritime country and ascending a height of 4000 feet in the central districts, we find both herbage and trees assume an altered character. The foliage of the latter is larger and deeper coloured, and they attain a height unknown to any in the hot low country. The herbaceous vegetation is there made up of *Ferns*, *Cyrtandria*, *Compositæ*, *Scitamineæ*, and *Urticaceæ*. The dense masses of lofty forest at that altitude are interspersed with large open tracts of coarse wiry grass, called by the natives *pattanas*, and of value to them, as affording pasturage for their cattle.

Between the altitudes of 4000 and 8000 feet, many plants are to be met with partaking of European forms, yet blended with tropical characteristics. The guelder rose, St John's wort, the *Nepenthes distillatoria* or pitcher plant, violets, geraniums, buttercups, sun-dews, ladies' mantles, and campanulas, thrive by the side of *Magnoliaceæ*, *Ranunculaceæ*, *Eleocarpeæ*, &c. The most beautiful flowering shrub of this truly alpine region is the rhododendron, which in many instances grows to the height of 70 feet. It is met with in great abundance in the moist plains of the elevated land, above Newere Ellia, flowering abundantly in June and July. There are two distinct varieties, one similar to the Neilgherry plant, having its leaves broad and cordate, and of a rusty colour on the under side: the other, peculiar to Ceylon, is found only in forests at the loftiest elevations, and has narrow rounded leaves silvery on the under side, growing to enormous heights and frequently measuring three feet round the stem. At these altitudes English flowers, grapes, herbs, and vegetables have been cultivated with perfect success, as also wheat, oats, and barley. English fruit-trees grow, but do not bear.

Timber.

The timber trees indigenous to Ceylon are met with at every altitude, from the sea-beach to the loftiest mountain peak. They vary much in their hardiness and durability, from the common cashew-nut tree, which when felled decays in a month, to the ebony and satinwood which for many years resist the attacks of insects and climate. The known woods amount to 416 varieties: of these, 33 are valuable for furniture, house, and shipbuilding, and are capable of standing long exposure to weather; 80 varieties are less valuable, though still very useful for certain purposes when not exposed to weather; 160 kinds are inferior, and used only for light common purposes, whilst the remainder are used but for firewood, or for making fences, rafts, &c. The most beautiful woods adapted to furniture work are the calamander, ebony, flower-satinwood, tamarind, nadun, dell, cadoemberge, kittool, cocoa-nut, &c.; some fine specimens of the far-famed upas tree of Java (*Antiaris toxicaria*) have been discovered in the Corregalle district of the island.

Palms.

The *Cocos nucifera*, or cocoa-nut palm, is a native of the island, and may justly be considered the most valuable of its trees. It grows in vast numbers along the entire sea-coast of the west and south sides of the island, and furnishes almost all that a Singhalese villager requires. Its fruit, when green, supplies food and drink, when ripe it yields oil. Its sap gives him toddy and arrack. The fibrous casing of the fruit when woven makes him ropes, nets, and matting. The nut-shells form drinking-vessels, spoons, &c. The plaited leaves serve as plates and dishes, and as thatch for his cottage. The dried flower-stalks are used as torches, the large leaf stalks as garden fences. The trunk of the tree sawn up is employed for every possible purpose, from knife-handles to door-posts; hollowed out it forms alike a canoe or a coffin. There are four kinds of this palm, the common, the king cocoa-nut, the dwarf, and the Maldive sorts.

The Palmyra and Areca palms grow luxuriantly and abundantly, the former in the northern, the latter in the western and central districts. The one is valuable chiefly for its timber, of which large quantities are exported to the Indian coasts; the other supplies the betel-nut in such common use amongst natives of the eastern tropics as a masticatory. The export trade in this latter to India and eastern ports is very considerable, amounting in some years to L.12,000.

Cinnamon.

Next in importance to the cocoa-nut palm amongst the indigenous products of Ceylon, is the cinnamon plant yielding the well-known spice of that name. See CINNAMON.

Fruits.

The fruits indigenous to Ceylon are few and insignificant. Others of more value have been introduced with success from various tropical and extra-tropical countries; amongst these are the citron, orange, lime, shaddock, banana, pomegranate, custard-apple, guava, grape, rambatam, alligator pear, &c.

Animals.

Foremost among the animals of Ceylon is the elephant, which though far inferior to those of Africa and the Indian continent is nevertheless of considerable value when tamed, on account of its strength, sagacity, and docility. These creatures are to be met with in greater or less numbers throughout most unfrequented parts of the interior. Occasionally they make inroads in herds upon the cultivated grounds and plantations, committing great damage. In order to protect these lands, and at the same time keep up the government stud of draught elephants, "kreals" or traps on a large scale are erected in the forests, into which the wild herds are driven; and once secured, they are soon tamed and fit for service. The oxen are of small size but hardy, and capable of drawing heavy loads. Buffaloes exist in great numbers throughout the interior, where they are employed in a half-tame state for ploughing rice-fields and treading out the corn. They feed upon any coarse grass, and can therefore be maintained on the village pasture lands where oxen would not find support. Of deer, Ceylon possesses three species of axis, and the porcine deer. The little Indian musk is common, and probably the larger musk is also found, though by some described as a deer. Hares very similar to our own are common, as are the squirrel and the porcupine, the wild boar, the bear, and the jackal. The panther is said to occur in the jungles, and the tiger was once common, but is now said by Dr Davy to be extinct in Ceylon. Among numerous monkeys the most remarkable are the purple-faced, the ouanderow, and the rollaway, with the kindred tribes of the macauco and the slow lemur. Pennant states that the two-toed sloth occurs in Ceylon, but this is considered as doubtful. One species of ant-eater is also found in this island; and on its coast the dugong is frequently seen.

Birds.

The Ceylonese birds are numerous, and many of them have splendid plumage, though, as in tropical countries generally, deficient in song. The most remarkable are the Indian roller, the oriole, the hoopoe, the pompadour pigeon, the wild pea fowl, the yellow-crowned thrush, several parrakeets, several fly catchers, the Ceylonese barbet, a pheasant with double spurs; and on the coasts the ibis, the anhinga, white snipes, and ducks are abundant in suitable localities. Crows of various species are numerous, and are protected by the inhabitants as being useful scavengers of the country; while hawks and eagles are found in the mountain districts. The hirundo esculenta, which furnishes in its edible nest the celebrated Chinese dainty, is said to build in the caves on the coast of Ceylon, and perhaps might supply an article of commerce.

Reptiles.

Serpents, according to Dr Davy, are not so numerous as generally is supposed, and most of them are harmless. The largest Ceylonese snake is the *anacondaia* of the natives, or the *Python bivittatus*—erroneously termed the boa constrictor, which is confined to America. This serpent grows to 20 or even to 30 feet. Davy describes four poisonous snakes, the Naja tripudians, or *Cobra de Capello* of the Portuguese. The next in frequency is the *Trigonocephalus hypnale*, a small irascible snake called carawilla by the natives. The *Tic polonga* or *Vipera elegans* is considered the most deadly snake of

Ceylon. the island, but is fortunately rather rare. It grows to 4 or 5 feet in length. The *Trigonocephalus nigromarginatus* is the rarest of the poisonous species, and grows to above 2 feet.

The most noted of other reptiles are the crocodile; and of the smaller Lacertidæ, *L. Iguana*, *L. calotes*, *L. gekko*, and the small flying lizard, the *Draco volans*. In the Kandian region one of the terrible pests to the traveller and to our soldiers is a very small leech that infests the swampy jungles and the banks of rivers. An interesting account of it is given by Davy. Scorpions, Scolopendræ, and huge spiders of the genera Avicularia and Mygale, are the dread of new-comers, as they often enter houses or lurk near them.

Insects exist in great numbers. Musquitoes are those which prove most annoying to Europeans, especially on their first arrival in the country. Several species of ant are common, the most troublesome of which are the large white ants which make their way through walls and floors, and in a few hours destroy every article of clothing which may be within their reach. Previous to the changes of the monsoon, vast flights of small yellow butterflies are observed passing over the island at a slight elevation, coming from the direction of the Indian continent, and going towards the ocean to the south. These swarms are often many miles in extent, and the migration will be kept up not unfrequently during several days.

Fish. A great variety of fish is met with in the rivers and bays of Ceylon, many of which are eaten by the natives alone, being coarse and full of bones. There are, however, some excellent varieties, equal at certain seasons to any fish in Europe: amongst these are a species of sole, the Labrus zeylanicus, a Scorpæna, and a country salmon called seer-fish. Large quantities of this latter, and a coarser description, are salted and dried for native consumption, the trade being very extensive. Besides these, three species of Balistes or trunk-fish occur on the coast, a curious Diodon, a large sword-fish, and the Tigrine shark.

Pearl fishery. Although the once far-famed and lucrative pearl fishery of this island has ceased since the year 1837, it will be well to give in this place a passing notice of the pearl-oyster, especially as a survey of the "banks" or beds off Aripo made in 1852 holds out promise of a good fishing at no distant date.

The banks on which these oysters are usually found, lay off the northern part of the west coast of Ceylon, at a distance of from 16 to 20 miles from the shore. They extend for many miles north and south, varying considerably in their size and productiveness. The oyster arrives at maturity in its seventh year; the pearl within is then of full growth, and if the fish be not then taken up, it will shortly die, and the pearl be lost.

The fishery, which is in the hands of the local government, took place in the month of March, when the water was perfectly calm and most favourable for the work of the divers. It was formerly rented to native speculators who paid a certain sum for the privilege of fishing with a fixed number of divers during a given period. In 1797, and the following year, the rental of the fishery realized L.123,982 and L.142,780 respectively. Since that time, the government have fished on their own account, selling the produce of each boat by auction on the beach before the fish could be examined. This mode, however, had not proved so lucrative as the old method; the annual returns never having exceeded L.87,000, and frequently falling as low as L.12,000; in some cases indeed amounting to but a few hundred pounds sterling. Various causes have been assigned for the failure of these fisheries. It may, however, be properly attributed to the mismanagement of an inspector of the pearl banks, who in 1836 took charge of them, and from neglecting to attend to the instructions given him by his predecessors, caused the wrong beds to be fished. The result was a complete failure of the fishery; the oysters which should have been brought up were left to die; young beds were disturbed, and from that time this large source of revenue has been lost to the island. A survey of the pearl banks made in March 1853 has induced the local government to look for a fishery of some extent in 1855 or the following year.

History. The island of Ceylon was known to the Greeks and Romans under the name of Taprobane, and in later times Serendib, Sirinduil, and Zeylan, have been employed to designate it by writers of the western and eastern worlds. Dib being the Sanscrit for island, Serendib is literally the island of Seren or Selen. Like most oriental countries, Ceylon possesses a great mass of antiquarian records, in which the real is so intimately and largely blended with the ideal, that the student finds it difficult to determine the respective limits of history and fable. The labours of Turnour have, however, helped to dissipate much of what was before confused and contradictory, and in his admirable translation of the "Mahawansa" we may trace the true current of Singhalese history.

The first colonization of Ceylon is by no means well ascertained, though, if we allow, as there is reason for doing, that the island was at a remote period joined to the Indian continent, it will not be difficult to conceive whence it derived its first inhabitants. In the great Hindu epic, the Ramayana, we learn of the conquest of a part of Ceylon by the hero Rama and his followers, who besieged and took the capital of its king Rawana. No permanent occupation of the country took place at this time, and the island continued to be governed by a number of petty sovereigns until the advent in 543 B.C., of Hyára an Indian prince who, arriving from the mainland with a small band of followers, succeeded in establishing himself as sole ruler of the country.

To this king is attributed the introduction of *caste* into Ceylon, an institution which, although far less rigorously observed than on the continent, is still maintained.

Under him and his successors Ceylon attained a degree of civilization scarcely to be looked for in that remote age of oriental despotism. The purity of the religious and moral code, the strict administration of justice, and the well-defined and carefully protected rights of the king and his many classes of subjects, excite our admiration not less than our astonishment. It is impossible however, to follow the subsequent current of Singhalese history through its many intricate windings. It must suffice if we say, that the descendants of Hijaya the conqueror continued to hold the reins of government with varied ability and unequal success. Some of them were distinguished for their learning, their military prowess, their benevolence, and the length of their reigns. Others lived amidst civil dissensions and foreign invasions, which not unfrequently cost them their lives. The incursions of the Malabars upon their territories were not less frequent and fatal than those of the Danes in our own country; during a period of four or five centuries, these marauders continued to pour their bands of armed men into the island; and so far had the country fallen off from its ancient prosperity and strength, that when in the year 1505 the Portuguese adventurer D'Almeida landed at Colombo, he found the island divided into seven separate kingdoms.

The first settlement of the Portuguese was effected in 1517, when Albergaria succeeded in obtaining permission from the king of Cotta, whose territories closely adjoined Colombo, to erect a small factory on the latter spot for purposes of trade. Once established, the new-comers lost no opportunity of strengthening their position and extending their intercouse with the natives. Stone walls quickly took the place of palisades, the factory became a fort; whilst bristling cannon commanded alike the approaches by land and the entrance by sea. Alarmed at these unequivocal signs of military possession, the Singhalese kings attempted to expel their newly-formed friends from the island, in which they were joined by the Moorish and other traders

Ceylon.

opposed to the progress of the Portuguese. But their efforts were both late and ineffectual; and after a series of unequal and sanguinary conflicts, the Europeans found themselves in secure possession of the west coast of Ceylon.

The bigotry and intolerance of the Portuguese were the constant source of dissension with the natives; and when, in the year 1601, the Dutch, under Admiral Spilbergen, landed on the east coast and sought the alliance of the king of Kandy, in the interior of the island, every encouragement was held out to them with the view of inducing them to aid in expelling the Portuguese. Nothing seems to have come of this until 1639, when a Dutch expedition attacked and razed the Portuguese forts on the east coast; and in the following year landed at Negombo, without, however, establishing themselves in any strong post. In 1643 Negombo was captured and fortified by the Dutch, and fifteen years later the fall of Colombo gave that people entire possession of the sea-board of Ceylon.

Pursuing a wiser policy than their predecessors, the Dutch lost no opportunity of improving that portion of the country which owned their supremacy, and of opening a trade with the interior. More tolerant and less ambitious of military renown than the Portuguese, they so far succeeded in their object as to render their commerce between this island and Holland a source of great profit. Many new branches of industry were developed. Public works were undertaken on a large scale, and education, if not universally placed within the reach of the inhabitants of the maritime provinces, was at least well cared for on a broad plan of government supervision.

That which they had so much improved by policy they were, however, unable to defend by force when the British turned their arms against them. A century and a half passed within seven degrees of the equator had wrought great changes in the physical and mental status of the Dutch colonists. The territory which in 1653 they had slowly gained by undaunted and obstinate bravery, they as rapidly lost in 1796 by imbecility and cowardice.

The first intercourse of the English with Ceylon took place as far back as 1766, when an embassy was despatched from Madras to the king of Kandy, without, however, leading to any result. On the rupture between Great Britain and Holland in 1795, a force was sent against the Dutch possessions in Ceylon, where so slight was the opposition offered, that by the following year the whole of their forts were in the hands of the English commander.

At first the island was placed under the care of the Honourable East India Company, but in 1802 reverted to the crown, whose dominion, however, extended no further than the maritime provinces. The central tract of hilly country, hedged in by impenetrable forests and precipitous mountain ranges, remained in possession of Wickrama Singha, the last of the Malabar dynasty of kings, who showed no signs of encouraging communication with his European neighbours.

Minor differences led in 1803 to an invasion of the Kandian territory; but sickness, desertion, and fatigue proved more formidable adversaries to the British forces than the troops of the Singhalese monarch, and peace was eventually concluded upon terms by no means favourable to the English. The cruelty and oppression of the king now became so intolerable to his subjects, that disaffection spread rapidly amongst them. Executions of the most horrible kinds were perpetrated. The utmost stretch of despotism failed to repress the popular indignation; and in 1814 the British, at the urgent request of many of the Adigars and other native chiefs, proceeded against the tyrant, who was captured near Kandy, and subsequently ended his days in exile. With him ended a long line of sovereigns, whose ancestral pedigree may be traced through upwards of two thousand years.

By a convention entered into with the Kandian chiefs on the 2d of March 1815, the entire sovereignty of the island passed into the hands of the British, who in return guaranteed to the inhabitants civil and religious liberty. The religion of Buddha was declared inviolable, and its rights, ministers, and places of worship were to be maintained and protected; the laws of the country were to be preserved and administered according to established forms; and the royal dues and revenues were to be levied as before for the support of government.

With the exception of a serious outbreak in some parts of the interior in 1817, which lasted for upwards of a year, and of two minor attempts at rebellion easily put down, in 1843 and 1848, the political atmosphere of Ceylon has remained undisturbed since the deportation of the last king of Kandy.

Government.

The affairs of the colony are administered by a governor, receiving his appointment from the crown for a period of five years. He is assisted by an executive and legislative council. The former is composed of the governor and four of the higher civil servants, and the commander of the forces; the latter is presided over also by the governor, and consists of fifteen members, nine of whom are official and six unofficial, selected by the governor from the English commercial and planting body and the native and burgher community. All legislative enactments are originated in the executive council, and must be published in the local gazette for three weeks before being adopted by the legislature, and when agreed upon require the sanction of the imperial government before they can become law.

A certain portion of the colonial expenditure is fixed by the home authorities, but a large amount is left for the votes of the legislative council. The executive of the island is carried on by a civil service, the members of which enter it at an early age, and have recently been called upon to undergo an examination in the Singhalese and Malabar dialects previous to promotion. The old routine system of rising by seniority has to a great extent been abolished, and merit professedly made the door to promotion.

The island is divided into six provinces, each having its chief and assistant government agent, who carry on the affairs of the district under the direct authority of the governor; receiving the local taxes and imposts, attending to the public highways and buildings, and seeing to the general welfare of the province. These provinces are the central or Kandian, the western, the southern, the eastern, the northern, and the north-western; which divisions are again parcelled out into minor districts, under native chiefs and headsman of various ranks, called in the Kandian country Adigars, Dessaves, and Corales, and in the maritime provinces Modeliars, Mohandirans, and Aratchies.

Justice.

The administration of justice is conducted by a supreme court of three judges, one of whom is chief justice; by district judges, by police magistrates, and commissioners of courts of request. Attached to the supreme court is a Queen's advocate, assisted by a deputy, the former having a seat in the executive and legislative councils. In each of the provinces is another deputy-advocate, who conducts the legal business of the government for the district. There is also a proctor paid by the crown to defend such prisoners as may be too poor to engage counsel.

The judges of the supreme court go on circuit twice in each year for criminal cases, as well as to hear civil appeals. Trial by jury prevails in all criminal cases, and sentence of death must be confirmed by the governor before being carried into execution.

The district judges are assisted by three native assessors chosen by rotation from the community, and have civil and limited criminal jurisdiction. The functions of the police magistrates and commissioners of courts of request assimilate to those of this country, the jurisdiction of the latter

Ceylon. extending to all cases of the value of L.50 and under. A police force, composed of natives, has been established in the towns, on the model of the London police. These men are habited in strict metropolitan garb, a dress so foreign and inconvenient as seriously to impair their efficiency.

Laws. In the central province, the Kandian law is administered under the convention of 1815, and in the maritime districts the Roman-Dutch law prevails; but in the present altered state of society in the island, there are many cases which the above fail to reach: all such are disposed of according to the law of England, which has been applied in a number of ordinances enacted by the local legislature, recently published in a collected form.

Language. The indigenous language of the island is the Singhalese, the present dialect of which is the Pali or sacred language of Ceylon, and in which all their Buddhistical annals are recorded. Singhalese is the current language throughout all the maritime provinces, except in the north and north-west, where Tamul is employed: it is likewise the dialect of the Kandian country. The Tamulian tongue is derived from the Sanscrit, and is employed by the Moors and Malabars of Ceylon, who are to be met with in great numbers on the sea-board, and who constitute almost the entire population of the northern portion of the island. The Dutch and Portuguese languages are spoken by the Burghurs or mixed descendants of the early colonists from Holland and Portugal.

Literature. The Singhalese possess an extensive literature, comprising sacred and scientific works in Pali and Sanscrit, as well as many plays and poems in their ordinary tongue. The "Mahawausa," their great historical epic, was translated from the Pali by the late Mr Turnour, and the labours of Mr Gogerly have since familiarized the reading public with Ceylonese Buddhistical literature. The Malabars possess a complete version of the Puranas in Tamul verse, besides numerous works on grammar, chemistry, pharmacy, astrology, magic, &c., and a number of tragedies and comedies. The Moors are not without works of considerable merit in the Tamul tongue, on various subjects. Their great epic poem, entitled "Seera," is pronounced by competent judges a more than ordinary composition.

Religion. The religion of Buddha is the dominant creed in Ceylon, professed by the entire population of the interior, and the greater portion of the Singhalese of the low country. Buddhism is essentially atheistic, placing belief in the eternal existence of matter alone, which matter possesses within itself the power of reproduction of beings without any other agency. Transmigration of a certain kind is a leading feature of this creed, and a series of distinct existences spent in austerities and good works has helped to form a superior order of beings called Buddhas. There have been many of these, and the last, called Sakya or Gotama Buddha, revealed the present faith. Gotama was born at Patalipatra, in India, B.C. 623; and after a long course of penance, prayer, and meditation, in strict solitude, is said to have attained his Buddhaship about B.C. 588. From India the ascetic passed to Ceylon, where he succeeded in establishing his faith, and finally died at the age of eighty.

The extensive ruins to be seen on the sites of the ancient cities of Anaradjapoora and Polonaruwa, bear testimony to the former estimation in which Buddhism was held in this island, and in some respects bear comparison with the remains of the sacred edifices of Egypt, Greece, and Rome. The Buddhist acknowledges no Supreme Being, and although we meet with a carved effigy of Buddha in almost every temple, no worship is offered to him as a deity: he is regarded but as a type of earthly goodness, wisdom, and beauty, deserving the imitation of his followers. He is believed by his perfection to have attained the sublime excellency of *Nirwana*, or cessation of existence, a state capable of being attained through many successive existences by every member of the human race. This *Nirwana* is peculiar to Buddhism, and differs from the Brahmins' absorption of the spirit into the supreme divinity. It is neither eternal repose, nor destruction of being, but a complete and final cessation of existence.

The code of morality established by Buddha is one of great purity; but since his advent the sacred writings have been so overlaid with commentaries as completely to destroy the original purity of the faith. The taking of the meanest life is strictly forbidden, while falsehood, intemperance, dishonesty, anger, pride, covetousness, are all denounced as incompatible with Buddhism. At the same time, the practice of charity, gratitude, contentment, moderation, forgiveness of injuries, patience, and cheerfulness, is as strictly enjoined.

The Buddhist priests are sworn to celibacy and poverty, and being incapable of possessing property of any kind are supposed to subsist on charity. They wear robes of yellow cotton, have their heads shaven, and walk barefooted and bareheaded. Service is performed daily in their temples, consisting of recitals of certain portions of the *Pitakas*, or Buddhist Scriptures, in the Pali dialect, which is unintelligible not only to the people but to the great majority of the priesthood. By degrees the Malabar conquerors of Ceylon incorporated the worship of Hindu deities with the simple religion of Buddha, and to most of the temples of the present day are attached buildings wherein this idol worship is carried on. Lands have been set apart from time immemorial to the support of these temples and their priests; and until a recent period annual grants for the maintenance of this religion were made by the local government, which also appointed the priests of the chief temples. This is no longer the case, and the management of the temples and temple-lands and the general affairs of their religion is now vested in the body of native chiefs and priests. At the same time, the government resigned to their custody the "Dalada," or sacred tooth of Buddha, a relic of much sanctity, and which was popularly believed to confer the sovereignty of the island upon its possessor. It had remained in charge of the British authorities since the convention of Kandy in 1815.

In the northern districts the Hindu religion prevails, the inhabitants being chiefly Malabars, who inherit from their ancestors the worship of Seeva.

Although Christianity was introduced into Ceylon as early as the sixth century, no remains of the faith or vestiges of churches were seen by the first Portuguese settlers. St Francis Xavier preached the Gospel, and permanently introduced Christianity in the middle of the sixteenth century. No efforts were spared by the Portuguese to induce the natives to embrace the Catholic religion, and they do not appear to have laid much stress upon the sincerity of their converts, who flocked to their churches in great numbers. The Dutch were equally zealous in the spread of the Reformed faith, but evidently with far less nominal success than their predecessors. The simplicity of the Presbyterian form of worship is but ill calculated to make any strong impression upon the senses of Oriental races; whereas the relics and ceremonies of the Romish Church appeal so warmly to their imagination, and have been made to approach so nearly to their own heathen ritual as even to insure a favourable reception amongst them.

Ceylon has recently been erected into a see, the junior bishop being Dr Chapman, who is assisted by an archdeacon and a number of chaplains, stationed at the chief towns. There are likewise a Scotch chaplain, a Dutch Presbyterian chaplain, and Malabar and Singhalese chaplains, appointed and paid by the government; the annual grants for ecclesiastical purposes amounting to about L.8000. There are besides these, clergymen of various Christian denominations employed as missionaries and teachers by the Society for

Ceylon.

the Propagation of the Gospel, the Church Missionary Society, the Wesleyan and the Baptist Missionary Societies.

Caste.

Although *caste* formed no part of the institutes of Buddha, it has been generally adopted, and the Singhalese, equally with the Malabars and Moors, divide themselves into four great divisions, viz., the rajahs or princes, the priests, the merchants, and the labourers. In this latter class there are not fewer than twenty-four castes, the lowest of whom are the rhodias or outcasts. The Malabars, besides the three chief divisions of priests, merchants, and landlords, have twenty-eight lower orders of persons. Between all of these there is much jealousy, intermarrying being considered a disgrace to the family of the higher caste; still this sometimes happens, and on the whole there is a gradual weakening of these barriers of native society, attributable to the spread of education and the civilizing influence of European residents.

Character.

The character of the Singhalese of the low and hilly country, if presenting no very pleasing traits, at least possesses nothing very repulsive. The religion of Buddha is not disgraced by rites such as render Hinduism so debasing to the mind of its followers; its mildness is reflected in the Singhalese disposition, wherein may also be traced the chilling apathetic influence of the creed of *Nirwana*. The most detestable vice is that of falsehood, which appears to have taken such a deep root in the native character as to bid defiance to teaching or example. Industry is a quality extremely rare amongst them; they are good agriculturists, but are averse to trade, the whole of which is in the hands of Burghurs, Tamuls, Moors, and other foreigners. There is a desire for improvement springing up amongst the Kandian and low country chiefs, and modeliers, who evince a great desire to send their sons to the government schools. This feeling, however, has not yet reached many below them.

Crime.

The criminal statistics of Ceylon show some remarkable results. Of 539 prisoners in one year, 368 only were brought to trial, and of those not more than 158 were convicted. Amongst these there were but two females, and not a single Burghur. Of this number 9 were found guilty of murder, 8 of manslaughter, 27 of other offences against the person, and 111 of offences against property. In the central province the prisoners were found in the following proportions:—Buddhists 100, Mohammedans 10, Roman Catholics 2, Protestants 2. In the northern province, the figures were Gentoos 95, Buddhists 5, Mohammedans 2, Roman Catholics 7, Protestants 1.

Education.

The educational work, so admirably begun by the Dutch colonists of Ceylon, although for a long period neglected by the early English governors, has been actively followed up during the past fifteen years. Convinced that the surest means for rooting out the atheistic heathenism of the natives is by the diffusion of sound knowledge, and that Christianity will often work its silent way through the printing-press when making no progress from the pulpit, the missionaries of all classes have laboured sedulously in the establishment of schools for instruction in English and the native tongues. Government money-grants are made to aid the various missionary schools which are conducted in union with, and on the model of those maintained by the authorities. For carrying out this aid as well as for supervising the educational establishments of the government, a "school commission" has been formed of clerical and lay members of various churches who make an annual report upon the progress of education throughout the island.

The government scholastic institutions comprise the Colombo Academy, consisting of an upper and a lower school, to which pupils are admitted on payment of very small fees, a normal training school at Colombo, English schools of good standing at Kandy, Galle, Trincomalee, and Jaffna, and upwards of eighty other schools chiefly mixed and vernacular. In 1846–7 the number of pupils in the Colombo Academy was 252, whose education, after deducting the monthly fees paid by the scholars, cost the government L.4, 10s. each. Since that period the fees were raised to thrice their former amount, the effect of which was that in 1851 there were but 19 pupils in the academy, costing each L.26, 10s. The students in the normal institution cost L.18, 10s. each; those of the central school at Galle cost L.8, 19s. 9d. each; and those at the Kandy school cost L.2, 16s. The scholars at the vernacular establishments cost annually but nine shillings each.

Ceylon.

The Church Mission have principal stations at Cotta, Baddegamme, Kandy, and Nellore. At two of these places they board and educate a number of youth of both sexes gratuitously, and at Cotta they impart a very superior education to young men and women to qualify them for missionary and scholastic labours. The American missionaries have similar establishments in the northern province, where a most complete education in the English tongue is bestowed upon upwards of 150 Tamul students of both sexes. The Wesleyan and Baptist missions are equally active throughout the island, chiefly, however, in vernacular education. In addition to these there are some regimental schools, and upwards of 900 village seminaries, mostly of a very inferior grade, in which it would be difficult to ascertain that anything really useful is taught. From the majority of these no returns exist by which we can judge of the number of their pupils.

The latest educational returns published show that in 87 government schools there were 1721 boys and 580 girls; in 314 missionary schools there were 8660 boys and 2320 girls; and in 263 private schools, mostly native, the pupils numbered 4912 boys and 64 girls: giving a total of 15,293 boys and 2965 girls, a result which shows that whilst of males 1 in every 98 of the population is being educated, of females the proportion to the whole population is not more than 1 in 500. The government expenditure in aid of education was, in 1852, L.7526, 10s. 5d.

Arts and sciences.

The fine arts have no existence in Ceylon, and the sciences, though not unknown, are in the lowest possible state. Singhalese astronomy is little else than astrology, whilst the native medical science is so overlaid with senseless theories and superstitions, so compounded of absurdities and contradictions, as to be wholly unintelligible to European practitioners.

Manufactures.

Although the Singhalese of the low country are by no means deficient in mechanical skill, as carpenters, cabinet-makers, wheelwrights, smiths, carvers on wood and metal, &c., they cannot be said to be a manufacturing people. Their cotton cloths, coir rope, and cocoa-nut oil, were all produced in the most primitive manner and with little doubt by precisely the same rude methods as were employed a thousand years ago.

The manufacture of coarse cotton towelling, table-linen, and other white goods, is carried on along the east, north, and north-west coasts, whilst the make of coloured goods is chiefly confined to the vicinity of Jaffna in the north. There are about four thousand looms in the island, each of which on an average will produce about L.3 to the weaver, who is in most cases of the Chalia caste. The towels made at Batticaloe are remarkably good and very durable, the best being made from native cotton. Dyeing is practised, but in a very slow and indifferent manner. Some of the best white cloths worn by native headmen are elaborately and neatly painted by hand, in a variety of picturesque patterns, and sell for several pounds sterling each.

It would be difficult to conceive any ruder method of making rope than that practised in a Singhalese rope walk, which is usually a long strip of open ground, shaded from the noon-day heat by lofty palm trees. When the coir fibre is of good quality, and the work-people are attentive, a very fine and serviceable rope is produced, admi-

Ceylon.

rably adapted for use in salt water. The country trading vessels employ no other cordage or rope than this, and indeed the planks of their small vessels are held together solely by coir yarn, without the aid of a single nail. The quantity exported from the island to all parts in 1850 amounted to 32,308 cwts., and in 1851 to 28,204 cwts.

The Singhalese mode of extracting the oil from the dried kernel of the cocoa-nut is of the most primitive kind. The *checkoo* or native mill is simply a clumsy wooden mortar in which a heavy pestle of hardwood is made to revolve by means of a pair of oxen at the end of a long pole, secured to the upper part of the pestle. The dried kernel being placed, finely cut, within the mortar, is by slow degrees squeezed free of its oil, which collects in the lower part of the mortar, and is thence removed by cocoa-nut shells. There are about five hundred checkoos at work during most part of the year at Colombo, Negombo, Galle, Trincomalee, and other chief towns, but chiefly at the three former places. Each checkoo usually produces above one gallon of oil per diem. Steam-power is employed in Colombo by European merchants in manufacturing this oil, which is now produced by them of superior quality, and in large quantities. The shipments of cocoa-nut oil from the ports of Colombo and Galle amounted in the year 1850 to to 792,791 gallons.

Agriculture.

The Singhalese are more attached to the pursuit of agriculture than any other occupation; and although their implements are of the rudest kind, and their processes the most simple, they nevertheless succeed in rearing successive crops of grain of good quality, from soil of no very great fertilizing powers. The chief culture in every part of the island is that of rice, the staple food in all eastern countries. The comparative poverty of the soil in the maritime districts is a barrier to the extensive production of grain; added to which the decay of the ancient works of irrigation in the eastern, northern, and north-western provinces, so essential to rice cultivation, renders large tracts of land which were formerly highly productive utterly valueless. In the western and southern provinces the presence of numerous rivers, canals, and lakes, enables cultivators to produce alternate crops of various kinds. In the Kandian country the soil is more generous, the climate less exhausting, and the supply of water from hill-streams far more certain and abundant. The agriculturists of those regions are thus frequently enabled to raise two crops of rice within the year from the same ground. Not only is every valley and open plain capable of tillage made to yield its crop of grain, but the steep sides of lofty hills are cut into terraces from base to summit, on which may be seen waving patches of bright green rice watered by mountain streams, conducted often from a great distance by means of earthen water-courses and bamboo aqueducts, stretching across rivers and over deep valleys, from hill to hill, attesting at once the patience, the industry, and the skill of the simple Kandian villagers.

Rice.

When the ancient monarchs of Ceylon held their imperial court at the now ruined city of Anarajaphorra, the busy hum of agricultural industry was heard from the confines of Bintenne to the northernmost point of the island. Artificial tanks and embankments for the supply of water equal in extent to the present areas of London, Liverpool and Manchester, imparted fertility to a region now known but as one vast desert. In those remote times, with a population of three or four millions, Ceylon was able to export large quantities of rice as her surplus production. Since the European period, with a population of barely a million and a half, the island, unable to grow sufficient for its own wants, has been in the habit of importing grain to the annual value of a quarter of a million sterling. There are eleven varieties of rice grown, of which five are sown in March and reaped in July; four are sown in May and gathered early in August, whilst two kinds are sown in June and November, one requiring five and the other two months to arrive at maturity. The yield of crops varies from four-fold in poor sandy soils to forty-fold from rich land. Many superstitions are observed by Singhalese cultivators, both in preparing the ground, sowing the seed, and harvesting the crop.

Tobacco.

Tobacco is extensively cultivated in Jaffna, Negombo, and some parts of the Kandian and Buah country; but although well grown it is imperfectly cured and is not of much value as an article of export. Cotton has long been a product of some importance to the villagers, who, however, grow it only for their own consumption, and thus it is not found in the list of exports. There are many other vegetable productions reared with more or less skill for local use, such as arrow-root, cassava, yams, chillies, and several varieties of pulse. Of these the only exportable item is the *chili*, a small species of capsicum.

Cotton.

Cinnamon.

The export trade in cinnamon will be found noticed under CINNAMON.

Coffee.

The most important cultivation is that of coffee, a branch of industry which, since the year 1841, has assumed a position of great and growing prominence. Coffee was an article of growth and export from Ceylon so far back as the time of the Portuguese, but like the cinnamon it grew wild without any attempt at cultivation. Patches of it were to be seen around the Kandian villages in wild luxuriance, and the berry gathered before ripe, and imperfectly cured, seldom possessed much flavour, and was lightly esteemed as an article of European commerce. Coffee cultivation on the West Indian plan was first commenced by Sir E. Barnes, the then governor of Ceylon in 1824, who hoped by his example to introduce coffee-planting by Europeans into the island. Until 1834, however, public attention does not seem to have been occupied with the subject, but in that year the falling off in the supplies from other quarters brought capitalists into the field, and when in 1836 the home duty on East India coffee was reduced to 6d. the lb. a great impulse was given to coffee planting in Ceylon. During that and the following year about 7000 acres of forest land were purchased for this object; and when at the end of a few years it became matter of notoriety that the soil and climate of Ceylon were capable of yielding a coffee equal in value to most kinds, the influx of capital from England for investment in this new branch of Ceylon industry became very great. The following quantities of crown land were thus disposed of during the periods indicated:—in 1840, ac. 42,841; in 1841, ac. 78,685; in 1842, ac. 48,533; and in 1843, ac. 58,336. Since that time the sale of land has sunk to a very low amount, owing to apprehensions as to the effect of free trade on the coffee market.

There are at the present moment about 300 estates under coffee culture, comprising in the aggregate 40,000 acres. Of these 35 are of 300 acres and upwards; 230 under 300 and above 100 acres; and 35 of less than 100 acres. The heaviest yield upon any estate has been one ton per acre, but few plantations exceed 15 cwts. the acre, and the majority of them are far below that return. The heaviest shipments in any year, those of 1853, give but 250,000 cwts. of plantation coffee, which being the produce of the 40,000 acres of planted land, shows an average of not more than $6\frac{1}{4}$ cwts. per acre. An annual yield of 10 cwts. per acre is considered a very favourable return for the capital invested.

The commercial crisis of 1847 gave a great check to coffee planting in Ceylon, and added to the extravagant outlay and ill-judged operations of previous years, caused the abandonment of some estates and the neglect of many others. The economy thus taught has been productive of much good, and at the present time plantation coffee is shipped at Colombo of better quality and 20 per cent. below the cost of crops seven years since. An estate of 300 acres may now be cleared, planted, and brought into bear-

ing for L.4000, exclusive of the cost of land, which ranges from L.1, 5s. to L.6 the acre.

The labour on coffee estates is performed by Malabar coolies, who annually emigrate from the coasts of India in large numbers; about 40,000 are usually employed in this manner at one time. The superintendence of the plantations is entirely in the hands of Europeans, who receive salaries varying from L.300 to L.100 a-year. The labour is paid for at the rate of 18s. a-month. The blossom appears in February. In October the gathering of the crop commences on most estates, and by the end of December the whole will be off the trees, when pruning at once takes place. The crops are partially dried on the plantations, but the curing is completed in Colombo, and by the end of May very little coffee remains for shipment. It is packed in casks of from 6 cwts. to 8 cwts. each; a very small quantity going in bags. The native grown crop, however, still goes home in the latter packages.

Sugar.

The cultivation of sugar was commenced in the neighbourhood of Kandy in 1836, and since in several other parts of the island, but without any permanent success, and there is now not more sugar grown than can be consumed in the island.

Cocoa-nuts.

Cocoa-nut planting has proved very lucrative to some English capitalists, but owing to the slow growth of the tree this has never been a very favourite investment. The land planted by Europeans with cocoa-nuts has been as follows:—in the northern province 5000 acres; western province 4000 acres; eastern province 2000 acres; southern province 800 acres: this extent is included in 104 plantations chiefly superintended by Europeans. The palm tree begins to yield in its fifth year, and does not come into full bearing before its tenth or eleventh year.

Commerce.

The trade of Ceylon has been greatly augmented since the opening of the cinnamon trade and the commencement of coffee planting. In 1832 the imports amounted to L.351,222; the exports to L.163,587. In 1842 the imports and exports amounted to L.622,447 and L.421,413 respectively. In 1852 those amounts were L.1,000,474 and L.948,400. The largest increase in exported produce has been in coffee, which from 17,287 cwts. in 1831 grew to 77,475 cwts. in 1841, and to 287,910 cwts. in 1851. In 1854 the crops of native and plantation kinds are expected to amount to 500,000 cwts.

The cinnamon trade of Ceylon forms a remarkable exception to the rule that by the removal of fiscal restrictions the consumption of articles will be increased. Cinnamon is now exported from Ceylon duty free, yet the annual demand for the spice is found to be no greater than when burdened with an export duty of 3s. the lb.

When the island was transferred from the administration of the East India Company to that of the crown in 1802, the government entered into a contract with the company, by which the latter acquired the exclusive privilege of exporting cinnamon from the colony. It was agreed that the Ceylon government should deliver annually 400,000 lb. of cinnamon; for which the company was to grant a credit of L.60,000, making the price of the cinnamon 3s. per lb.

In 1814 the company agreed to allow to the Ceylon government a sum of L.200,000 sterling for surplus profits on their sales of cinnamon; and to give in future, L.101,000 sterling annually, instead of L.60,000, for a supply of 400,000 lb. of that commodity. This contract was entered into for seven years, and it does not appear that during this period the stipulated quantity of cinnamon was ever delivered. In 1821 the exclusive privilege of exporting cinnamon was given up by the company; and in 1833 the government abandoned their monopoly of the trade, throwing it open to the public, but levying a duty of 3s. per lb. on its exportation.

In 1835 inferior or third sort was allowed to be shipped on payment of 2s. the lb. Two years later the duty on the best sorts was lowered to 2s. 6d.; and in 1843 the duty on all kinds was fixed at 1s. It was since reduced to 4d.; and in 1853 the article was declared duty free. These periodical reductions of duty were in all cases followed by heavy shipments of the spice; the sole effect of which has been to overstock the European markets, and reduce its price beyond the reduction of duty. The annual European consumption is at the present time precisely what it was fifty years ago; thus proving that articles of mere luxury are not affected by the laws which govern the consumption of the necessaries of life. Of the exports, four-fifths are to Great Britain; of the imports, one-third is from the United Kingdom, and the remainder chiefly from India. The imported goods from Great Britain consist of cotton manufacture, glass-ware, hardware, millinery, hosiery, metals, tools, beer, wines, &c.; those from India are mainly rice and coarse cotton cloth. The exports to Europe being larger than the imports thence, the balance of value is drawn for by bills of exchange, a part of which are negotiated in India to pay for rice, the rest for rupees sent down to Ceylon to pay the Malabar coolies on the coffee estates, who carry three-fourths of their earnings out of the island.

The trade of Ceylon is carried on by upwards of twenty European firms, and eight or nine native houses; the latter confining their transactions to British India. Besides these, there are nearly a dozen European estate-agents in Kandy, and a great number of small native dealers, called "Chitters," in connection with Madras and Bombay firms.

There are no export duties, and the duty on imports is five per cent. on the declared value, with some few exceptions, such as arms, wines, spirits, and grain. In 1852 the revenue derived from customs duties was L.121,354, 8s. 9d.

The coasting and Indian trade is carried on by country-built brigs and dhomies, a craft peculiar to Ceylon. Of the former there are 56 of 3176 tons in the aggregate, and 559 dhomies, of a tonnage equal to 24,270 tons, belonging to the island. The value of the former is L.6 per ton, and of the latter L.1 per ton. In 1836 the custom-house shipping entries gave 1331 vessels inwards, and 1200 outwards; in 1852 they gave 3140 inwards, and 3074 outwards.

Banking.

The banking business of the island is conducted by branches of the Oriental Bank Corporation of London, and the Mercantile Bank of Bombay in Colombo and Kandy. The former establishment possesses the privilege of issuing notes of 10s. and upwards.

Revenue and expenditure.

Although the figures composing the revenue of Ceylon, as compared with former years, would appear to be unfavourable, they are nevertheless not so when it is remembered that upwards of L.150,000 once derived from the pearl fishery and cinnamon monopoly are no longer available. In 1821 the revenue was L.459,699; in 1831 it was L.420,170; in 1841 it was L.341,937; and in 1852 it was L.411,806.

An analysis of the income and expenditure for 1848 gives the following results: Expenditure—civil, L.177,673; military, L.75,219; judicial, L.65,224. Revenue, L.58,480; ecclesiastical, L.10,806; educational, L.9873; pensions, L.34,100; total, L.431,325. Income: Taxes on food, salt tax, import duties, grain tax, &c., L.156,108; excise and stamps, L.91,143; customs duties except on food, L.43,345; tolls, L.20,571; total taxation, L.311,167; sales of crown lands, government property, rations to troops and arrears, L.103,589; total income, L.414,756. A further analysis of the above shows that the proportion contributed by the Singhalese population of 1,491,000, is at the rate of 2s. 2d. for each individual per annum, which is paid by the various districts in the following ratio: Western province, 3·80; central province, 2·20; southern province, 1·40; northern province, 1·10; north-western province, 1·0; eastern province, 0·50. (*Parl. Papers on Ceylon*, 1848 *to* 1852;

Sir J. E. Tennent's Report on State of Ceylon, 1846; *Knighton's History of Ceylon*, 1845; *Gazetteer of Ceylon, by S. C. Chitty; Sir J. E. Tennent's Christianity in Ceylon; Journals of Asiatic Society of Ceylon*, 1846 *to* 1851; *Ceylon Magazine*, 1847; *Reports of School Commission; Ceylon Examiner*.) (J. C—R.)

CHABLIS, a town of France, on the Seray, department of Yonne, arrondissement and 10 miles east of Auxerre. It gives name to a celebrated white wine produced in the vicinity. Pop. 2500.

CHABRIAS, a celebrated Athenian general, who first assumed the command about the year B.C. 392. He defeated the Spartans at Ægina (B.C. 388), and again at Naxos (B.C. 376). With Iphicrates and Callistratus he commanded at Corcyra, and repulsed Epaminondas before the walls of Corinth. In 366 B.C. he was charged with treachery in advising the surrender of Oropus to the Thebans, and is said to have been defended by Plato. His unpopularity on this account led him to prefer a foreign command under Tachos, king of Egypt, who had revolted from the Persians. On the breaking out of the Social War (B.C. 357), Chabrias assumed the command of the Athenian fleet, and fell fighting in his ship, which had rashly penetrated the harbour of Chios. He was famous for the invention of a manœuvre, which consisted in receiving a charge on the left knee, with the spears of the front ranks pointed against the enemy, and the shields resting on the ground. For this invention a statue was erected to his honour at Athens, in which he is represented in the position described.

CHÆRONEIA, a Bœotian town on the Thermodon, a small tributary of the Cephissus, near the borders of Phocis. It is celebrated in history as having been the scene of three great battles, the first (B.C. 447) in which the Athenians were defeated by the Bœotians; the second (B.C. 388) in which Philip defeated the confederate forces of the Athenians and Bœotians; and the third (B.C. 86) in which Sulla defeated the generals of Mithridates. A tumulus still visible near the site of the modern Kapurna, marks the grave of the Bœotians who fell in the second of these engagements, and in the village itself are some remains of an ancient citadel, and a theatre excavated out of the rock on which the citadel was built. Chæroneia was the birthplace of Plutarch.

CHAFERY, a forge in which an ancony or square mass of iron, hammered at the finery into a bar in the middle, is reduced to a complete bar by hammering down the rough ends to the shape of the middle part.

CHAFFINCH. See Index to ORNITHOLOGY.

CHAGRES, a river and town. See PANAMA.

CHAIN, a series of rings or links connected or fitted into one another.

CHAIN, in surveying, a measure of length, composed of a certain number of links made of iron wire. Gunter's chain, which is that commonly used in measuring land, contains 100 such links, each of $7\frac{92}{100}$ inches; consequently it is equal to 4 poles or 66 feet.

CHAIN-BRIDGES. See IRON BRIDGES.

CHAIN-PUMP. See HYDRODYNAMICS, chap. iii.

CHAIN-SHOT, two balls connected together by a chain, and used at sea to cut down masts, and destroy the shrouds and rigging of a ship.

CHAISE, a sort of light open chariot, or calash. Aurelius Victor attributes the first introduction of post-chaises to Trajan; but it is generally ascribed to Augustus, and was probably only improved by Trajan.

CHALAZÆ (χαλαζαῖος, knotted), a name applied to the two knotty chords attached to near the poles of the yolk of an egg; being a plexus of the fibres of the membranes, connecting the yolk and white together, and serving to maintain the yolk in such a position that the cicatricula shall always be uppermost, and consequently nearest the source of heat during incubation.

CHALCEDON, or rather CALCHEDON, a maritime town of Bithynia, called also PROCERASTIS and COLPUSA, directly opposite Byzantium. It was founded by a colony from Megara, on a site so obviously inferior to that which was within their view on the opposite shore, that it received from the oracle the name of the *The City of the Blind*. In its early history it shared the fortunes of Byzantium, was taken by the satrap Otanes, vacillated long between the Lacedæmonian and Athenian interest, and at last fell into the hands of the kings of Bithynia, by the last of whom it was bequeathed to the Romans. It was taken and partly destroyed by Mithridates, but recovered during the empire. It fell under the repeated attacks of the barbarian hordes, who crossed over after having ravaged Byzantium, and furnished an encampment to the Persians under Chosroes. Its ruin was completed by the Turks, who used it as a quarry from which to draw the building materials for Constantinople. At Chalcedon was held the fourth general council (A.D. 451), which condemned the heresy of Eutyches.

CHALCIDIUS, a famous Platonic philosopher, who probably flourished during the sixth century. He was the author of an esteemed commentary on the Timæus of Plato, which Meursius edited and printed at Leyden in 1617, 4to, and which J. A. Fabricius has inserted at the end of the second volume of the works of St Hippolytus, Hamburg, 1718, fol. Critics are divided in opinion respecting this author. Fabricius asserts that he was a Christian; and Giraldi supposes that he was even a deacon of the church at Carthage. But the Abbé Goujet, in his dissertation inserted in the first volume of the *Mémoires de Littérature*, maintains the contrary opinion, on the grounds that Chalcidius adopts the opinions of Plato, doubts the inspiration of the books of Moses, and speaks of the dogmas of Christianity with indifference, or at least without indicating whether he believed them or not. Mosheim and Brucker, however, place him among the syncretist or eclectic philosophers, who amalgamated the philosophy of Plato with the doctrines of Christianity. It is the opinion of Mosheim that he never professed Christianity; Brucker again is of a contrary opinion, and says that he shared the errors of Platonism in common with many whose Christianity was never questioned.

CHALCIS. See NEGROPONT.

CHALCOCONDYLES, or CHALCONDYLES, a Byzantine historian of the fifteenth century, who was present as the ambassador of John VII. (Palæologus) during the siege of Constantinople, A.D. 1446. His history is divided into ten books, and contains many curious episodes in regard to the then condition of the European states, including descriptions of Germany and England.

CHALDEA. See BABYLONIA.

CHALDÈE LANGUAGE, a dialect of the Hebrew. See LANGUAGE.

CHALDEE *Paraphrase*. See SCRIPTURE, sect. x.

CHALDRON, an English dry measure, = 36 bushels.

CHALICE (κύλιξ, a cup), the cup used to administer the wine in the sacrament. The use of the chalice is by the Church of Rome denied to the laity, who communicate only in one kind, the clergy alone being allowed the privilege of communicating in both.

CHALET, the Swiss name for the houses of the peasants, and for the huts erected to shelter cattle in the mountains.

CHALK (from *calx*), in Latin called *creta*, a species of carbonate of lime, found abundantly in Britain, France, Norway, and other parts of Europe. The island of Candia is said to have received its ancient name of *Creta* from the quantity of chalk found there. Chalk is used as an antiacid; and from the readiness with which it imbibes liquids,

it is much employed as an absorbent. When powdered and freed from gritty particles by washing, it forms the substance called *whitening*, or Spanish white, used to polish metalline utensils and glass. It is simply prepared as follows: mix chalk that has been well triturated with a large quantity of water, allow the silicious and ferruginous particles to subside, and then decant the supernatant fluid into a very fine sieve or linen bag, where the whitening will be deposited.

Black CHALK, a mineral used by artists for drawing. It is a variety of bituminous shale, the *schiste-graphique* of Haüy.

French CHALK, steatite or soapstone, a hydrated silicate of magnesia and alumina. It occurs of several colours, as white, brown, green, &c.; and is used in the preparation of crayons, the manufacture of porcelain, for polishing marble, and as the basis of certain cosmetic powders.

Red CHALK is an indurated clayey ochre used for similar purposes. It is *reddle*, or earthy clay-ironstone of the mineralogist.

CHALK-*Formation*. See GEOLOGY.

CHALK STONES, the name given to the concretions which occur in the joints of persons who have long suffered from gout. These consist of urate of ammonia, but were once supposed to be of a chalky nature, and thence acquired the above name.

CHALLENGE (Norman *calenge*, an accusation), a cartel or invitation to a duel or combat. See DUEL.

CHALMERS, ALEXANDER, (1759–1834,) an eminent biographer, was a native of Aberdeen. His first literary performances were contributions to several London periodicals, and he was for some time editor of the Morning Herald. Besides editions of the works of Shakspeare, Beattie, Fielding, Johnson, Warton, Pope, Gibbon, Bolingbroke, and others, he published *A General Biographical Dictionary* in 32 vols.

CHALMERS, *George*, an historical, antiquarian, and political writer of considerable eminence, was descended from the family of Chalmers of Pittensear, in the county of Moray, and was born at Fochabers in the end of the year 1742. After completing his academical course at King's College Aberdeen, he removed to Edinburgh, where he studied law for several years. In 1763, he went to America to assist in recovering a considerable tract of land in Maryland. His prospects in America induced him to settle as a lawyer at Baltimore in Maryland, where he continued to practise successfully till the outbreak of the disputes between the two countries, which ended in the establishment of American independence. He espoused and advocated the cause of the Royalist party against the ablest of their opponents; but public opinion was so decidedly engaged on the opposite side, that he soon found it expedient to abandon all his professional prospects, and seek refuge in his native country. For the losses he had sustained as a colonist he received no compensation, and several years elapsed before he obtained an appointment which placed him in a state of comfort and independence.

In the mean time Mr Chalmers applied himself with great diligence and assiduity to the investigation of the history and establishment of the English colonies in North America; and enjoying free access to the state-papers, and other documents preserved among the plantation records, he obtained much original and important information. His work entitled "Political Annals of the present United Colonies, from their Settlement to the Peace of 1763, &c.;" 4to, London, 1780, was intended to have formed two volumes; but the second, which should have contained the period between the British revolution of 1688 and the peace of 1763, never appeared. The first volume, however, is complete in itself, and traces the original settlement of the different colonies, and the progressive changes in their constitutions and forms of government, as affected by the state of public affairs in the parent kingdom. Independently of its value as being compiled from original documents, it bears evidence of great diligence and research, and it has been of essential benefit to later writers.

In August 1786 Mr Chalmers was appointed chief clerk to the committee of privy-council, on matters relating to trade and foreign plantations, and continued to discharge its duties for nearly forty years. During this period he wrote most of those numerous pieces of which a list will be found at the close of this article, and devoted himself to the illustration of the antiquities and topography of Scotland.

Most of his minor pieces it is not necessary to mention particularly. His life of Ruddiman throws considerable light on the state of literature in Scotland during the earlier part of the last century; but is too stately and inflated in style. His volumes on the Shakspeare controversy are full of curious matter, but on the whole display a great waste of erudition in the attempt to show that papers which *had* been proved forgeries *might* nevertheless have been genuine. Neither was he more fortunate in fixing the authorship of Junius' Letters on Hugh Boyd. His editions of Sir David Lyndsay and Churchyard are valuable and curious. His Life of Queen Mary is founded on a MS. left by the Rev. John Whitaker, the historian of Manchester; but he informs us that he found it necessary to "rewrite the whole." The history of that ill-fated queen occupied much of Mr Chalmer's attention. One of the latest acts of his life was to expose an attempt to resuscitate some fictitious love-letters said to have passed between Mary and Bothwell, and which had fallen into deserved oblivion.

But Chalmers's greatest work is his "Caledonia." It is divided into four books, treating successively of the Roman, the Pictish, the Scottish, and the Scoto-Saxon periods from A.D. 80 to 1306. In these books there is presented, in a condensed form, an account of the people, the language, the history civil and ecclesiastical, and the agricultural and commercial state of Scotland, during the first thirteen centuries of our era. Between the publication of the 2d and 3d vols. an interval of fourteen years elapsed, and in the preface to the latter volume the author announced his expectation that the work would be completed in two years. This expectation, however, was not destined to be realized.

Besides the "Caledonia," Mr Chalmers had for many years been engaged in collecting materials for other works of not less important and laborious a nature. One of these works was a *History of Scottish Poetry*; another a *History of Printing in Scotland*. Each of them he thought likely to extend to two large quarto volumes, and on both he expended an unusual amount of enthusiasm and energy. He had also prepared for the press an elaborate history of the Life and Reign of David I., who died in 1153. In his later researches he was ably assisted by his nephew Mr James Chalmers.

Mr George Chalmers died at his house, James' Street, Buckingham Gate, London, May 31, 1825, after a few days illness, in the eighty-third year of his age. He was a member of the Royal and Antiquarian Societies of London, an honorary member of the Antiquarian Society of Scotland, and of other learned societies. In private life he was undoubtedly an amiable man, although his writings are disfigured by a dogmatic and presumptuous tone which procured him many opponents. He is besides chargeable with a want of taste, and inaccurate scholarship, which appears too prominently in his keen attempts to silence, at all hazards, those whom he considered the detractors of Mary. Among his avowed antagonists in literary warfare the most distinguished were Malone and Steevens, the Shakspeare editors; Mr Mathias, the author of the Pursuits of Literature; Dr Jamieson, the Scottish lexicographer; Mr Pinkerton, the historian; Dr Irving, the biographer of the Scottish poets; and Dr Currie of Liverpool. But with all his failings in judgment and in matters of taste, Mr Chalmers was a valuable writer. He

uniformly had recourse to original sources of information; and his patriotic endeavours to illustrate the history, literature, and antiquities of his native country, attended as they were by very great pecuniary sacrifices, deserve our gratitude and esteem.

The following is a list of his works:—1. *Life of Daniel De Foe*, prefixed to an addition of his *History of the Union*, Lond. 1786; and of *Robinson Crusoe*, 1790, 8vo. 2. *Life of Sir John Davies*, prefixed to his Historical Tracts regarding Ireland. Lond. 1786, 8vo. 3. *Collection of Treaties between Great Britain and other Powers*. Lond. 1790, 2 vols. 8vo. 4. *Life of Thomas Paine*, the author of *Rights of Man*. (Tenth edition), Lond. 1793, 8vo, published under the assumed name of "Francis Oldys, A.M. of the university of Pennsylvania." 5. *Life of Thomas Ruddiman, A M.;* to which are subjoined *New Anecdotes of Buchanan*. Lond. 1794, 8vo. 6. *Prefatory Introduction to Dr Johnson's Debates in Parliament*. Lond. 1794, 8vo. 7. *Vindication of the Privilege of the People in respect to the constitutional right of Free Discussion, &c.* Lond. 1796, 8vo. (Anonymous.) 8. *An Apology for the Believers in the Shakspeare Papers, which were exhibited in Norfolk Street*. Lond. 1797, 8vo. 9. *A Supplemental Apology for the Believers in the Shakspeare Papers, &c.* 1799, 8vo. 10. *Appendix to the Supplemental Apology*. 1800, 8vo. 11. *Life of Allan Ramsay*, prefixed to an edition of his Poems. Lond. 1800, 2 vols. 8vo. The *Remarks on Ramsay's Poetry*, prefixed to this edition, were from the pen of the late Lord Woodhouselee. 12. *Life of Gregory King*, prefixed to his *Observations on the State of England in* 1696. Lond. 1804, 8vo. 13 *The Poetical Works of Sir David Lyndsay of the Mount, with a Life of the Author, Prefatory Dissertations, &c.* Lond. 1806, 3 vols. 8vo. 14. *Caledonia, or an Account, Historical and Topographic, of North Britain, &c.* 2 vols. Lond. 1807–1810, 4to. 15. *A Chronological Account of Commerce and Coinage in Great Britain, from the Restoration till* 1810. Lond. 1810, 8vo. 16. *Considerations on Commerce, Bullion, and Coin, Circulation and Exchanges, &c.* 1811, 8vo. 17. *An Historical View of the Domestic Economy of Great Britain and Ireland, from the earliest to the present times, &c.* (being a new edition of the *Comparative Estimate*). Edinb. 1812, 8vo. 18. *Opinions of eminent Lawyers on various points of English Jurisprudence, chiefly concerning the Colonies, Fisheries, and Commerce of Great Britain*. Lond. 1814, 2 vols. 8vo. 19. *A Tract* (privately printed) *in answer to Malone's Account of Shakspeare's "Tempest."* Lond. 1815, 8vo. 20. *Comparative Views of the State of Great Britain and Ireland before and since the War*. Lond. 1817, 8vo. 21. *The Author of Junius ascertained, from a concatenation of circumstances, amounting to moral demonstration*. Lond. 1817, 8vo. 22. *Churchyard's Chips concerning Scotland; being a Collection of his Pieces relative to that Country, with Notes and a Life of the Author*. Lond. 1817, 8vo. 23. *Life of Mary Queen of Scots, drawn from the State Papers, with six Subsidiary Memoirs*. Lond. 1818, 2 vols. 4to, and reprinted in 3 vols. 8vo. 24. *The Poetical Remains of some of the Scottish Kings, now first collected*. Lond. 1824, 8vo. 25. *Robene and Makyne, and the Testament of Cresseid, by Robert Henryson*, edited and presented by Mr Chalmers as a contribution to the Bannatyne Club. Edin. 1824, 4to. 26. *Caledonia*, vol. iii. 1824, 4to. 27. *A Detection of the Love-Letters lately attributed in Hugh Campbell's work to Mary Queen of Scots*. Lond. 1825, 8vo.

Chalmers, *Dr Thomas*, a distinguished Scottish divine, was born at Anstruther in Fifeshire, on the 17th March 1780. He was early destined to the church, and while only eleven years old was enrolled as a student in the university of St Andrews. Having completed his collegiate course, in which he devoted himself almost exclusively to the study of mathematics, in January 1799 he was licensed as a preacher of the gospel by the presbytery of St Andrews. Instead of entering at once on the duties of his profession, he spent the two following winters in Edinburgh, attending the lectures of Professors Stewart, Playfair, Robison, and Hope. In May 1803 he was ordained as minister of Kilmany, a small parish in Fifeshire, about nine miles from St Andrews. During the preceding winter he had acted as assistant to Mr Vilant, professor of mathematics in the university of that city, who for many years had been laid aside by ill health. The novelty, however, of his method, and the singular enthusiasm that he exhibited and excited were distasteful to those attached to the old routine of university education; and at the close of the session he was informed that his further services would not be required. Indignant at the fancied injustice thus done him, he adopted the singular expedient of opening mathematical classes of his own during the succeeding winter, which, though discountenanced in every way by the university authorities, many of the students were attracted to attend. The winter of 1803–4 was a very busy and exciting one. During the week he taught three classes in St Andrews; prepared and delivered there a course of lectures on chemistry, largely illustrated by experiments,—appearing at the same time in the pulpit of Kilmany every Sunday. Having sufficiently redeemed his reputation by the great success which attended them, his mathematical classes were not resumed. The lectures on chemistry were frequently redelivered in his own and in many adjoining parishes, to the surprise and delight of many rural audiences. In 1805 the chair of mathematics in Edinburgh became vacant, and he appeared, but unsuccessfully, as a candidate. In 1808 he published an *Inquiry into the Extent and Stability of National Resources*, a treatise originated by the alarm which Bonaparte's commercial policy had created in Britain, and intended to elucidate some of those questions in political economy which the existing state of affairs had raised. He was preparing a new edition of this work when a series of domestic bereavements, and a severe illness that brought him to the brink of the grave, and laid him aside from all duty for upwards of a year, turned his thoughts and life into a new channel. Dr Brewster had invited him to become a contributor to the Edinburgh Encyclopædia; at his own request the article Christianity had been assigned to him, and he was now engaged in preparing it. In studying the credentials of Christianity, he received a new impression of its contents. A sustained but abortive effort to attain that pure and heavenly morality which the Gospel of Christ requires, led on to that great spiritual revolution the nature and progress of which his journal and letters enable us to trace with such distinctness. When he resumed his duties, an entire change in the character of his ministry was visible to all. The report of discourses so earnest and eloquent as those now delivered, and of household visitations conducted with such ardent zeal, soon spread beyond the limits of his own neighbourhood. His reputation as an author received at the same time a large accession by the publication in a separate form of his article on Christianity, as well as by several valuable contributions to the *Edinburgh Christian Instructor*, and the *Eclectic Review*. So strong, however, at that time was the public bias against those evangelical doctrines which he had embraced, that when a vacancy occurred in Glasgow, and his friends brought him forward as a candidate, it was only after extraordinary efforts, and by a narrow majority, that his election was carried in the town-council.

In July 1815 he was formally admitted as minister of the Tron church and parish. A blaze of unparalleled popularity at once broke around him as a preacher. A series of discourses which he had preached on the connection between the discoveries of astronomy and the Christian revelation, were published in January 1817. Never either before or since has the same reception been given to any volume of sermons in our language. Within a year, nine editions and 20,000 copies of the volume were in circulation. Soon after its appearance he visited London, and occupied for the first time one or two of the pulpits of the metropolis. The crowds were enormous, the applause loud and universal. "All the world," writes Mr Wilberforce, "wild about Dr Chalmers." His extraordinary popularity remained undiminished during the eight years that he remained in Glasgow.

His preparation for the pulpit, however, formed but a small part of his labours. In visiting his parish, which contained a population of about 11,000 souls, he speedily discovered that nearly a third of them had relinquished all connection with any Christian church, and that their children were growing up in ignorance and vice. The appalling magnitude of the evil, and the certainty of its speedy and frightful growth,

at once arrested and engrossed him. To devise and execute the means of checking and subduing it, became henceforth one of the ruling passions of his life. Attributing the evil to the absence of those parochial influences, educational and ministerial, which wrought so effectually for good in the smaller rural parishes, but which had not been brought to bear upon the overgrown parishes of our great cities, from all spiritual oversight of which the members of the Establishment had retired in despair, his grand panacea was to revivify, remodel, and extend the old parochial economy of Scotland. Taking his own parish as a specimen, and gauging by it the spiritual necessities of the city, he did not hesitate to publish it as his conviction that not less than twenty new churches and parishes should immediately be erected in Glasgow. All, however, that he could persuade the town-council to attempt, was to erect a single additional one, to which a parish containing no fewer than 10,000 souls, was attached. This church built at his suggestion was offered to him and accepted, in order that he might have free and unimpeded room for carrying out his different parochial plans.

In September 1819 he was admitted as minister of the church and parish of St John's. The population of the parish was made up principally of weavers, labourers, factory workers, and other operatives. Of its 2000 families, more than 800 had no connection with any Christian church. The number of its uneducated children was countless. In this, as in his former parish, Dr Chalmers' first care and efforts were bestowed upon the young. For their week-day instruction, two commodious school-houses were built, four well-qualified teachers were provided, each with an endowment of L.25 per annum; and at the moderate school-fees of 2s. and 3s. per quarter, 700 children had a first-rate education supplied. For the poorer and more neglected, between forty and fifty local sabbath schools were opened, in which more than 1000 children were taught. The parish was divided into 25 districts, embracing from 60 to 100 families, over each of which an elder and a deacon were placed—the former taking the oversight of their spiritual, the latter of their temporal interests. Over the whole of this complicated parochial apparatus Dr Chalmers presided, watching, impelling, controlling every movement. Nor was his work that of mere superintendence. He visited personally all the families, completing his round of them in about two years, and holding evening meetings, in which he addressed those whom he had visited during the week. Many families were thus reclaimed to the habit of church-going, and many individuals deeply and enduringly impressed by the sacred truths of Christianity.

The chief reason why Dr Chalmers removed from the Tron parish to that of St John's was that he might have an opportunity of fairly testing the efficacy of the old Scottish method of providing for the poor. At this period there were not more than 20 parishes north of the Forth and Clyde in which there was a compulsory assessment for the poor. The English method of assessment, however, was rapidly spreading over the southern districts of Scotland, and already threatened to cover the whole country. Dr Chalmers dreaded this as a great national catastrophe. Having studied in its principles, as well as in its results, the operation of a compulsory tax for the support of the poor, he was convinced that it operated prejudicially and swelled the evil it meant to mitigate. It was said, however, that though the old Scotch method of voluntary contributions at the church-door administered by the kirk-session was applicable to small rural parishes, it was inapplicable to the large and already half-pauperized parishes of our great cities. Dr Chalmers asked the magistrates of Glasgow to commit the entire management of the poor of the parish of St John's into his own hands, and he undertook to refute that allegation. He was allowed to try the experiment. At the commencement of his operations, the poor of this parish cost the city L.1400 per annum. He committed the investigation of all new applications for relief to the deacon of the district, who had so small a number of families in charge, that by spending an hour among them every week, he became minutely acquainted with their character and condition. By careful scrutiny of every case in which public relief was asked for; by a summary rejection of the idle, the drunken, and the worthless; by stimulating every effort that the poor could make to help themselves, and when necessary, aiding them in their efforts; a great proportion of these new cases were provided for without drawing upon the church-door collections; and such was the effect of the whole system of Christian oversight and influence, prudently and vigorously administered, that in four years the pauper expenditure was reduced from L.1400 to L.280 per annum.

At the commencement of his ministry in St John's, Dr Chalmers began a series of quarterly publications on *The Christian and Civic Economy of Large Towns*, devoted to the theoretic illustration of the various schemes of Christian usefulness which he was carrying on; presenting himself thus to us as at once their skilful deviser, their vigorous conductor, their eloquent expounder and advocate. But the fatigues of so toilsome a ministry began to exhaust his strength; and he was already longing to exchange the personal for the literary labours of his profession, when the vacant Chair of Moral Philosophy in the University of St Andrews was offered to him. This offer, the seventh of the same kind that had been made to him during his eight years' residence in Glasgow, he accepted, entering on his new duties in November 1823, and devoting the next four years of his life to their fulfilment. Hitherto metaphysics and ethics had been taught conjunctly by the professors of moral science in the Scotch colleges, while, in teaching the latter, allusions to the peculiar doctrines of Christianity had generally and often carefully been avoided. Looking upon mental philosophy as belonging properly to another chair, Dr Chalmers confined his prelections to the philosophy of morals, entering at large upon the duties man owes to God as well as those he owes to his fellow-men, endeavouring throughout to demonstrate the insufficiency of natural religion to serve any other purpose than that of a precursor of Christianity. Many of his lectures, as remodelled afterwards and transferred to the theological chair, are to be found now in the first and second volumes of his works. In the purely ethical department, those discussions in which he made important and original contributions to the science, are those occupied with the place and functions of volition and attention, the separate and underived character of the moral sentiments, and the distinction between the virtues of perfect and imperfect obligation. It was not so much, however, for their scientific speculations that his lectures in the moral philosophy class-room were distinguished, as for that fervour of professional enthusiasm with which they were delivered, and which proved so healthfully contagious. Beyond the intellectual impulse thus communicated, his frequent references to the great doctrines of Christianity, and still more the force of his inviting example, kindled to a very remarkable degree the religious spirit among the students of St Andrews; and not a few of them—including many men who have since highly distinguished themselves—have been led thereby to consecrate their lives to missionary labour.

In November, 1828, Dr Chalmers was transferred from the chair of moral philosophy in St Andrews to that of theology in Edinburgh. In this wider theatre he was enabled to realize all his favourite ideas as to the best methods of academical instruction. To the old practice of reading to his students a set of carefully prepared lectures he added that of regular *viva-voce* examination on what was thus delivered, and introduced besides the use of text books, communicating through them a large amount of information; and coming into the closest and most stimulating contact

with his pupils, he attempted to combine the different systems pursued in the English and the Scottish universities. In the professorial chair there have been many who, with larger stores of learning, have conducted their students to greater scientific proficiency; but none have ever gone beyond him in the glowing impulse, intellectual, moral, and religious, that he conveyed into the hearts of the ardent youths who flocked around his chair; and to that spirit with which he so largely impregnated the young ministerial mind of Scotland, may, to a large extent, be traced the Disruption of the Scottish Establishment.

The leisure for literary labour which professorial life afforded was diligently improved. At St Andrews he resumed the work which his departure from Glasgow had suspended, and in 1826 published a third volume of the *Christian and Civic Economy of Large Towns.* This was followed in 1827 by his treatise on the *Use and Abuse of Literary and Ecclesiastical Endowments*, the ablest defence of endowments in our language, a work which itself would have won celebrity for its author. For many years his chief ambition had been to complete a treatise on political economy, a science which had been a favourite one from youth. In St Andrews, besides his ordinary course on ethics, he had opened a class for instruction in this science, and had been delighted to find how attractive it had proved. As soon as he had got through his first course of theological lectures in Edinburgh, he resumed this subject, and embodied the reflections and preparations of many years in a work on *Political Economy*, published in 1832. Many of the particular doctrines of this work have not met with general acceptance. The public mind, however, has been gradually coming round to a belief in that great truth which this volume was mainly intended to enforce,—that a right moral is essential to a right economic condition of the masses,—that character is the parent of comfort. His work on *Political Economy* was scarcely through the press, when, on invitation from the trustees of the Earl of Bridgewater, Dr Chalmers was engaged on a treatise *On the Adaptation of External Nature to the Moral and Intellectual Constitution of Man*, which appeared in 1833. Literary honours, such as were never united previously in the person of any Scottish ecclesiastic, crowned these labours. In 1834 he was elected fellow of the Royal Society of Edinburgh, and soon after made one of its vice-presidents. In the same year he was elected corresponding member of the Royal Institute of France, and in 1835 the university of Oxford conferred on him the degree of D.C.L.

Hitherto Dr Chalmers had taken but little part in the public business of the church. He had given some effective help in the prosecution of two measures—the one for the abolition of pluralities, and the other for the improvement of theological education. The death of Dr Andrew Thomson, who had long been the able leader of the Evangelical party, and the obtaining by that party of the ascendancy, called him to lead the counsels and doings of the church. One of the earliest acts of the General Assembly of 1834, the first in which the Evangelical party had the majority, was to place Dr Chalmers at the head of a committee appointed to promote the extension of the church. In this office he had a double duty to discharge—to solicit the government to make a grant out of the public revenue, and to stimulate the friends of the church by their own voluntary efforts to meet the spiritual necessities of the country. In both departments extraordinary efforts were made, but with very different results. The Whig government, insecure in its hold of power and dependent to some extent on the political assistance of the Scottish Dissenters, could be induced to do nothing beyond appointing a committee of inquiry which led to no practical result. It was otherwise when Dr Chalmers appealed to the country. That appeal was made with singular ardour and eloquence. When circulars, pamphlets, and reports had done their uttermost, he made a tour through a large part of Scotland, addressing the various presbyteries and holding public meetings in the most populous districts. Year after year swelled the fund that these efforts created, till at last in 1841, when he resigned his office as convener of the Church Extension Committee, he had to announce that in seven years upwards of L.300,000 had been contributed to this object and 220 new churches had been built.

This great movement on behalf of church extension was finally checked by another in which Dr Chalmers was destined to play a still more conspicuous part. In 1834, the General Assembly, after declaring it to be a fundamental principle of the church that "no minister shall be intruded into any parish contrary to the will of the congregation," had enacted, that in every instance the dissent of the majority of the male heads of families, being communicants, should be a bar to the settlement of a minister. This act commonly called the Veto Law, was based upon the old constitutional practice of the Call in which the people invited the minister to undertake the pastoral office, on which invitation alone the spiritual act of ordination was grounded. The church believed herself to possess the power of determining what kind and amount of popular concurrence was necessary before the pastoral tie was formed by ordination. She had often exercised that power to the effect of setting aside the nominee of the patron. When invited in such instances to interfere, the civil courts had refused, on the ground that the church was acting within the limits of her acknowledged authority. In other instances the civil courts had often reviewed decisions of the church courts, but only with a view of regulating the title to the benefice. But now the power of the church to pass such a law as that of the Veto was challenged, and the civil courts claimed a right not only to regulate the destination of the benefice, but to control and overrule the decisions of the church. In the parish of Auchterarder, containing a population of 3000 souls, only two individuals signed the call, while 287 out of 300 dissented; but in an action raised at the instance of the presentee, the Court of Session decided that his rejection by the church was illegal. This decision the House of Lords, on appeal to it, confirmed; Lords Brougham and Cottenham in delivering judgment, stating it expressly to be their opinion, that in settling a minister the church had no legal right to look beyond his qualifications as to "life, literature, and morals." In this decision, as involving a forfeiture of the benefice, the church acquiesced, declaring at the same time her intention, for her own spiritual objects, to interpret for herself the statutes which established her, and announcing her unaltered purpose to protect her congregations from the intrusion of unacceptable ministers. It speedily appeared that she was not to be permitted to carry out these resolutions if the Court of Session could prevent. The presbytery of Dunkeld rejected a licentiate presented by the Crown to the parish of Lethendy on the ground of his having been vetoed by the people. The Crown acquiesced and issued a new presentation. At the instance of the first presentee the Court of Session interdicted the presbytery from ordaining the second. The church ordered the presbytery to proceed with the ordination. It did so, and was summoned in consequence to the bar of the civil court, solemnly rebuked, and informed that in the next instance of such disregard by the church of the interdict of the civil court, imprisonment would be the punishment. In the parish of Marnoch, with a population of 2800 souls, only one individual signed the call; an overwhelming majority dissented; but in defiance of the law of the church and in obedience to the Court of Session, the presbytery of Strathbogie, by a majority of 7 to 3, resolved to proceed to the ordination. To prevent this ordination the church suspended the seven ministers who formed the majority. The Court of Session not

only annulled that suspension and prohibited the church from intimating or executing it, but interdicted all ministers from preaching or administering any of the sacraments within any of the parishes of the seven suspended clergymen. The church held such interference as a violation of her spiritual independence, and proceeded as if no such sentence of the civil court had been passed; many of the most distinguished ministers, Dr Chalmers and Dr Gordon among the rest, preaching in those parishes in the face of interdicts served on them personally. The seven suspended clergymen treated in the same way the supreme ecclesiastical authority, and on the 21st January 1841, in opposition to an express order of the General Assembly, consummated the ordination. By the following General Assembly these clergymen were deposed from the office of the ministry. The Court of Session immediately thereafter pronounced the deposition null and void. Other like instances occurred. The collisions between the two supreme courts became frequent and most unseemly. Matters were running into inextricable confusion. The church appealed to the government to interfere. At first the Whigs were in power, but they declined to interfere. In 1841, Sir Robert Peel was placed at the head of a government strong enough to have applied the remedy, and the hopes of the church were excited. Still no measure was introduced. Under the guidance of Dr Chalmers the church pursued her course with steady unfaltering step; but she was not prepared to prolong the controversy indefinitely. Denying the right of the Court of Session to act as it had done, she freely conceded to the legislature the right of determining on what terms she held her temporalities; and if, fairly appealed to, the legislature declared that she held them on condition of rendering such obedience to the civil courts as they now required, she felt that she had no alternative but either to renounce her own principles or relinquish the temporalities. At a solemn convocation held in November 1842 a large number of ministers signed and published a declaration that if no measure of relief were granted they would resign their livings. Up to the last, however, it was not believed that any very extensive secession would take place. In January 1843, the government not only refused to grant the protection the church required, but put a final and peremptory negative on her claims of spiritual independence. And in March the House of Commons did the same by a large majority; the Scotch members, however, voting in the proportion of more than two to one in her favour. The controversy was now closed, and it remained only for those clergymen who felt that they could not with a good conscience submit to the civil restraint imposed upon the church, to adopt the only expedient now left to them and retire from the Establishment. On the 18th May 1843, 470 clergymen withdrew from the General Assembly and constituted themselves into the Free Church of Scotland, electing Dr Chalmers as their first moderator.

For two years previous to this final step, Dr Chalmers had foreseen the issue, and in preparation for it had drawn up a scheme for the support of the outgoing ministers. For a year or two afterwards the establishment and extension of that fund, to which the Free Church owes so much of her stability, engaged a large share of his attention. He then gradually withdrew from the public service of the church, occupying himself with his duties as Principal of the Free Church College, and in perfecting his "Institutes of Theology." In May 1847, he was summoned before a committee of the House of Commons to give evidence regarding that refusal of sites for churches in which a few of the landed proprietors of Scotland who were hostile to the Free Church were still persisting. He returned from London in his usual health, and after a peaceful Sabbath (May 30th), in the bosom of his family at Morningside, he bade them all good night. Next morning, when his room was entered and the curtains of his bed withdrawn, he was found half erect, his head leaning gently back upon the pillow, no token of pain or struggle, the brow and hand when touched so cold as to indicate that some hours had already elapsed since the spirit had peacefully departed.

During a life of the most varied and incessant activity, spent much too in society, Dr Chalmers scarcely ever allowed a day to pass without its modicum of composition. He had his faculty of writing so completely at command that at the most unseasonable times, and in the most unlikely places, he snatched his hour or two for carrying on his literary work. He was methodical indeed in all his habits, and no saying passed more frequently from his lips than that punctuality is a cardinal virtue. His writings now occupy more than 30 volumes. He would permanently perhaps have stood higher as an author had he written less, or had he indulged less in that practice of reiteration into which he was so constantly betrayed by his anxiety to impress his ideas upon others. It would be premature to attempt to estimate the place which his writings will hold in the literature of our country. We may briefly indicate however, some of the original contributions for which we are indebted to him. As a political economist he was the first to unfold the connection that subsists between the degree of the fertility of the soil and the social condition of a community, the rapid manner in which capital is reproduced, (See Mill's *Political Economy*, vol. i., p. 94), and the general doctrine of a limit to all the modes by which national wealth may accumulate. He was the first also to advance that argument in favour of religious establishments which meets upon its own ground the doctrine of Adam Smith, that religion like other things should be left to the operation of the natural law of supply and demand. In the department of natural theology and the Christian evidences, he ably advocated that method of reconciling the Mosaic narrative with the indefinite antiquity of the globe which Dr Buckland has advanced in his Bridgewater Treatise, and regarding which Dr Chalmers had previously communicated with that author. His refutation of Mr Hume's objection to the truth of miracles is perhaps his intellectual *chef d'œuvre*, and is as original as it is complete. The distinction between the laws and disposition of matter, as between the ethics and objects of theology, he was the first to indicate and enforce. And it is in his pages that the fullest and most masterly exhibition is to be met with of the superior authority as witnesses for the truth of Revelation of the Scriptural as compared with the ex-Scriptural writers, and of the Christian as compared with the heathen testimonies. In his "Institutes of Theology," no material modification is either made or attempted on the doctrines of Calvinism, which he received with all simplicity of faith, as he believed them to be revealed in the Divine word, and which he defended as in harmony with the most profound philosophy of human nature, and of the Divine providence.

The character of Dr Chalmers' intellect was eminently practical. The dearest object of his earthly existence was the elevation of the common people. Poor-laws appeared to him as calculated to retard this elevation; he therefore strenuously resisted their introduction. The Church of Scotland appeared to him as peculiarly fitted to advance it; he spoke, he wrote, he laboured in its defence and extension. "I have no veneration," he said to the royal commissioners in St Andrews, before either the Voluntary or the Non-intrusion controversies had arisen, "I have no veneration for the Church of Scotland *quasi* an establishment, but I have the utmost veneration for it *quasi* an instrument of Christian good." Forcing that church to intrude unacceptable ministers, and placing her in spiritual subjection to the civil power, in his regard stripped her as such an instrument of her strength, and he resolutely but reluctantly gave her up.

It is as a mover of his fellow men, as the reviver of evangelistic feeling in Scotland, and as a leader in that great

movement which terminated in the erection of the Free Church, that Dr Chalmers will fill the largest place in the eye of posterity, and occupy a niche in the history of Scotland and of the church. Various elements combined to clothe him with public influence—a childlike, guileless, transparent simplicity, the utter absence of everything factitious in matter or manner—a kindliness of nature that made him flexible to every human sympathy—a chivalry of sentiment that raised him above all the petty jealousies of public life—a firmness of purpose that made vacillation almost a thing impossible, a force of will and general momentum that bore all that was moveable before it—a vehement utterance and overwhelming eloquence that gave him the command of the multitude, a scientific reputation that won for him the respect and attention of the more educated—the legislative faculty that framed measures upon the broadest principles, the practical sagacity that adapted them to the ends they were intended to realize—the genius that in new and difficult circumstances could devise, coupled with the love of calculation, the capacity for business details, and the administrative talent that fitted him to execute—a purity of motive that put him above all suspicion of selfishness, and a piety unobtrusive but most profound, simple yet intensely ardent. (W. H—A.)

CHALONER, Sir Thomas, a statesman and poet, descended from a noble family in Wales, was born in London about the year 1515, and educated at Cambridge. He was introduced at the court of Henry VIII., and sent on the English embassy to the court of Charles V., whom he attended in his ill-fated expedition against Algiers in 1541. Soon after the fleet left Algiers, he was shipwrecked by night on the coast of Barbary, but had the good fortune when swimming to catch hold of a cable, by which he was drawn up into his own ship. Mr Chaloner returned soon after to England, and was appointed first clerk of the council, an office which he held during the rest of that reign. On the accession of Edward VI. he became a favourite of the Duke of Somerset, and attending that nobleman to Scotland, was knighted by him after the battle of Musselburgh in 1547. The protector's fall, however, at once put a stop to his expectations, and involved him in difficulties. During the reign of Queen Mary, his Protestantism brought him into some danger; but having many powerful friends, he had the good fortune to escape. On the accession of Queen Elizabeth he appeared again at court, and was appointed ambassador to the Emperor Ferdinand I., with marks of distinguished favour. On his return he was sent in the same capacity to Spain, when, on account of the differences which then existed between the two courts, he met with harsh and insolent treatment, which induced him to send a request to the queen for his recal. He returned accordingly in 1564, and resided in London till his death, which took place in the following year. He was buried with great pomp in St Paul's—Sir W. Cecil, then secretary of state, being chief mourner.

Sir Thomas Chaloner was a man of varied talents, and made a considerable figure as a poet.

Principal works,—*Poetical Works*, edited by Dr William Malim; *De Republica Anglorum Instaurandâ*, lib. x, written in Spain; *The Praise of Folie*, from the Latin of Erasmus; *In laudem Henrici Octavi Carmen Panegyricum*; *The Office of Servants*, from the Latin of Cognatus; and several other smaller pieces.

Chaloner, *Sir Thomas*, the younger, though inconsiderable as an author, deserves to be recorded as a skilful naturalist, and particularly as the founder of the alum works in Yorkshire, which have since proved so highly advantageous to the commerce of this kingdom. He was the only son of the preceding, and was born in the year 1559. Being very young at the time of his father's death, the lord treasurer Burghley took charge of his education, and sent him ultimately to Oxford, where, like his father, he discovered considerable talents for Latin and English poetry. About the year 1580 he made the tour of Europe, and returned to England before 1584, when he became a frequent attendant at the court of Queen Elizabeth. In 1591 he was knighted; and, some time afterwards, discovered the alum mines on his estate at Gisborough, near the river Tees, in Yorkshire.

Towards the latter end of the queen's reign, Sir Thomas visited Scotland; and rose so high in the estimation of James I. that he was appointed governor to Prince Henry, whom he constantly attended; and when his royal pupil visited Oxford, he was honoured with the degree of master of arts. How he was employed after the death of the prince is not known. He died in the year 1615, and was buried at Chiswick in Middlesex. His eldest son William was created a baronet in the year 1640; but the title became extinct in 1681.

He wrote, *Dedication to Lord Burghley*, of his father's poetical works, 1579; *The Virtue of Nitre*, 4to, Lond. 1584.

CHALONS-Sur-Marne (the ancient *Catalauni* or *Duro-catalauni*), the capital of an arrondissement of the same name, and of the department of Marne, France, stands on the right bank of the Marne, here crossed by a fine stone bridge, 93 miles east of Paris, with which it is connected by a railway. In early times this was a place of considerable importance, having been embellished and fortified by the Romans; and was the scene of two celebrated battles, the one fought in 273, when Tetricus was defeated by the forces of Aurelian, and the other in 451, when Attila, king of the Huns, was defeated by Aëtius and his allies. Chalons is irregularly and ill built, surrounded by old walls, the houses being mostly of wood, lath, and plaster. It has, however, some fine public buildings, as the cathedral, originally built about 450, and mostly rebuilt in 1672; the churches of Notre Dame, St Alpin, and St Jean, town-hall, barracks, and the residence of the prefect. It is the seat of a bishopric, and has tribunals of primary instance and commerce, an agricultural society, communal college, two seminaries, schools of arts and trades, theatre, and a public library of 20,000 volumes. The *Jard* is a magnificent promenade to the east of the town, covering an area of 19 acres. Chalons has manufactures of woollen, linen, and cotton goods, leather, &c., and a considerable trade in corn, wine, hemp, and wool. Pop. (1851) 14,468.

Chalons-*sur-Saône* (the ancient *Cabillonum*), a town of France, capital of the arrondissement of the same name in the department of Saône-et-Loire, 63 miles north of Lyons. It is a neat and well built town, pleasantly situated in an extensive plain on the right bank of the Saône, at the mouth of the *Canal du Centre*, and having on the opposite bank of the river its suburb St Laurent, with which it is connected by a fine old stone bridge. The chief structures are the cathedral, a Gothic edifice of the latter part of the thirteenth century, and occupying the site of a church founded in 532; the church of St Pierre, with two lofty steeples; the hospitals of St Laurent and St Louis; town-hall; an obelisk erected in 1793 to commemorate the opening of the canal, and several public fountains. It has tribunals of primary instance and commerce, an exchange, agricultural society, communal college, and a public library of 10,000 volumes. Its manufactures are extensive and various, among which is *essence d'orient*, prepared from the scales of the bleak (*Cyprinus Alburnus*), and used for the fabrication of mock pearls. Its commerce is very considerable and flourishing, as the town is an entrepot of goods both for the north and south of France. Pop. (1851) 15,719. Chalons was the capital of the old division of Chalonnais, in the province of Burgundy.

CHALUS, a small town of France, department of Haute Vienne, arrondissement and 16 miles N.W. of St Yrieix, on the Tardociere, which divides it into an upper and lower

town. Pop. 1200. Richard Cœur de Lion was here mortally wounded by an arrow in 1199.

CHALYBEATE (χάλυψ, steel), impregnated with particles of iron or steel; applied to medicines containing iron, as well as to mineral waters impregnated with that metal.

CHAM or KHAN, the title given to the sovereign princes of Tartary. The word in the Persian signifies *mighty lord;* in the Sclavonic, *emperor.* Sperlingius, in his dissertation on the Danish term *köning*, king, thinks the Tartar *kham* may be thence derived. The term *cham* or *kham* is also applied, among the Persians, to great lords, and governors of provinces.

CHAMADE, in war, a certain beat of a drum, or sound of a trumpet, inviting the enemy to a parley; as for making a proposition to capitulate, or for a truce. Menage derives the word from the Italian *chiamata*, from the Latin *clamare* to call aloud.

CHAMAS, ST, a town of France, department of Bouches-du-Rhône, on the north bank of the lagoon De Berre, 24 miles N.W. of Marseilles. It is well built, and is divided into two parts by a hill, through which a large tunnel has been cut. It has a fine church; a large powder magazine, which supplies Toulons; and a trade in oil and olives, which are shipped from its port on the lagoon. In the vicinity is a Roman bridge of a single arch, with a triumphal arch at each extremity. Pop. 3000.

CHAMBER (*camera*), an apartment in a house, more particularly a sleeping apartment. It also denotes a hollow or cavity; as the *chamber of a mortar*, in which the powder lies.

CHAMBERLAIN (Latin *camerarius*, from *camera*, a chamber), the keeper of the chamber. During the time of the Roman empire, the *cubicularii* or chamberlains were officers in immediate attendance on the person of the emperor. Their special duty was to announce visitors, superintend the domestic arrangements of the palace, &c.

The lord great chamberlain of England was originally a person of the highest importance, and took rank after the lord privy seal. The office is hereditary, and belonged at one time to the De Veres, from whom it descended by the female line into the family of Bertie. On the death of the second last Duke of Ancaster, it passed into the houses of Cholmondeley and Willoughby d'Eresby. From these families alternately a lord great chamberlain is appointed on the death of the reigning monarch.

The lord chamberlain of the king's household is an officer whose duty it is to appoint physicians, surgeons, chaplains, and tradesmen for the royal family. He also licenses plays, and has the right of selecting the theatrical companies that perform before the reigning monarch.

The chamberlain of the corporation of the city of London is appointed by the liverymen. His duties are to decide on differences that may arise between masters and apprentices, and to admit on oath persons entitled to the freedom of the city. Appeal is open from his decisions to the lord mayor. He is also treasurer of the corporation, and in this capacity receives the various items which compose the city revenue, and discharges such debts as it may incur. The salary of this officer from different sources varies from L.2000 to L.3000 per annum.

CHAMBERLAYNE, EDWARD, author of the *Angliæ Notitia*, was born in Gloucestershire in 1616, and made the tour of Europe during the distractions of the civil war. After the Restoration he went as secretary with the Earl of Carlisle, who carried the order of the garter to the king of Sweden. He was appointed tutor to the Duke of Grafton, natural son of Charles II., and was afterwards engaged to instruct Prince George of Denmark in the English tongue. He died in 1703, and was buried in a vault in Chelsea churchyard. His monumental inscription mentions six books of his composition which were buried along with him, and thus perished.

CHAMBERLAYNE, *John*, son of the preceding, entered Trinity College in 1685, and died in 1724.

He wrote a Continuation of the *Angliæ Notitia*, entitled *Magnæ Britanniæ Notitia; Dissertations, historical, critical, theological, and moral, on the Events of the Old Testament:* and also several translations from Ostervald, Nieuwentyt, Brandt, and others.

CHAMBERS, SIR WILLIAM (1725–1796), an eminent architect, was born at Stockholm. In his youth he made a voyage to China; and his drawings of Chinese costume and architecture were afterwards published. He was treasurer to the Royal Academy of Fine Arts in London, and furnished the design for Somerset House.

CHAMBERS, *David*, a Scotch historian, priest, and lawyer, was born about the year 1530. He was educated in the university of Aberdeen, and afterwards went to France and Italy. At Bologna, in 1556, he was a pupil of Mariannus Sozenus.

After his return to Scotland, he was appointed by Queen Mary parson of Suddy and chancellor of Ross. He was soon afterwards employed in digesting the laws of Scotland, and was engaged in 1566 in publishing the acts of the Scottish parliament by authority. He was also appointed one of the lords of session, and continued faithful to the interests of the queen till her adherents were obliged to seek refuge in other kingdoms. Chambers went to Spain, where he was received by Philip; and thence to Paris, where he was welcomed by Charles IX., to whom, in 1572, he presented his History of Scotland. He died at Paris in the year 1592.

He wrote *Histoire abrégée de tous les Roys de France, Angleterre, et Escosse; La recherche des Singularités plus remarkable concernant le Estat d'Escosse;* and a *Discours de la légitime succession des Femmes.*

CHAMBERS, *Ephraim*, author of the *Cyclopædia* which bears his name, was born at Kendal, Westmoreland. His parents were Presbyterian Dissenters, and gave him a commercial education. By them he was apprenticed to Mr Senex the globe-maker. It was during Mr Chambers's residence with this skilful mechanician that he contracted that taste for science and learning which directed all his pursuits. At this time he had formed the design of his great work, the *Cyclopædia;* and some of the articles in it were written behind the counter. In order to devote himself wholly to this undertaking, he quitted Mr Senex, and took chambers at Gray's Inn, where he chiefly resided during the rest of his days. The first edition of the *Cyclopædia*, which was the result of many years' intense application, appeared by subscription in 1728, in two vols. fol. It was dedicated to the king, and procured for Mr Chambers the honour of being elected fellow of the Royal Society. In less than ten years a second edition was printed, with corrections and additions (in 1738); and this was followed by a third in the following year.

In addition to the *Cyclopædia*, Mr Chambers was concerned in the publication of *The Literary Magazine* (begun 1735), to which he contributed a variety of articles, and particularly a review of Morgan's *Moral Philosophy*. He was likewise engaged with Mr John Martyn, professor of botany at Cambridge, in preparing for the press a translation and abridgment of the Philosophical History and Memoirs of the Royal Academy of Sciences at Paris. This undertaking was completed in 5 vols. 8vo, and published in 1742, some time after Chambers's decease, under the joint names of himself and Mr Martyn. In a subsequent publication, Mr Martyn severely censured the share which his colleague had had in the abridgment of the Parisian papers. The only other work ascribed to him is a translation of the *Jesuit's Perspective*, from the French. Mr Chambers's close attention to his studies at length impaired his health, and obliged him to go to the south of France. He died soon after his return to England in 1740, and was buried in Westminster Abbey, where a modest inscription, written by himself, marks the place of his burial.

CHAMBERY, a city of Italy, kingdom of Sardinia, capital of a province of the same name, and also of the duchy of

Savoy. It is pleasantly situated in a fertile district, between two hills, on the rivers Leisse and Albana, 46 miles S.S.W. of Geneva. The town, however, is irregularly and ill built, and has only one good street. The principal edifices are the cathedral, hotel Dieu, castle, theatre, and barracks. Several of the squares are adorned with fountains. The old ramparts of the city have been converted into public walks. It is the seat of an archbishop, of the military governor of the duchy, and of the superior tribunal; and has also a Jesuit college, royal academical society, society of agriculture and commerce, public library, museum, botanic garden, and many charitable nstitutions. It has manufactures of silk-gauze, lace, leather, soap, hats, &c.; and a considerable trade in liqueurs, wine, lead, copper, and other articles. In the vicinity is Charmettes, for some time the residence of Rousseau. Pop. (including garrison) 18,000.

CHAMBORD, a magnificent Gothic chateau of France, department of Loire-et-Cher, 10 miles east of Blois, on the left bank of the Cosson. It was commenced by Francis I. in 1532, carried on by Henry II., and at length finished by Louis XIV. It is built of black stone, with a profusion of towers, turrets, and minarets; and the interior is fitted up with great magnificence. The park is inclosed by walls seven leagues in circumference. The castle was for some time the residence of Stanislaus king of Poland, father-in-law of Louis XV., and afterwards of Marshal de Saxe. It was given by Napoleon to Marshal Berthier, from whose widow it was purchased by subscription in 1821 for the Duke of Bordeaux. It gives the title of Count to the last of the older branch of the Bourbons.

CHAMELEON. See Reptilia.

CHAMFRAIN, or Champfrein, an ancient piece of defensive armour for the head of a horse.

CHAMIER, Daniel, an eminent Protestant divine, born in Dauphiny. He was for many years preacher at Montellimart, an office which he exchanged in 1612 for the chair of divinity at Montaubon, where he was killed by a cannon-ball during the siege in 1621.

He wrote *Panstratia Catholica*, 4 vols. fol. 1620, edited by Turretin, and abridged in 1 vol. fol. by Frederic Spanheim the elder; *De Œcumenico Pontifice, libri sex*, 8vo, Geneva, 1601; and *Corpus Theologicum*, Geneva, 1653.

CHAMISSO, Adelbert von, a German naturalist and poet, born in Lorraine in 1781, of a noble family, that was obliged to emigrate to Berlin in the commencement of the first French revolution. There young Chamisso was received as one of the pages to the queen, and in 1798 entered the Prussian army, in which he served until after the peace of Tilsit. He then took up his residence in France, where he spent ten years in the assiduous cultivation of natural history. On his return to Germany he published the novel of Peter Schlemil, the man who loses his own shadow, a production of great power and originality. In 1814 he was offered the situation of naturalist to an expedition round the world, undertaken at the expense of Count Numjanzow, chancellor of the Russian empire. The expedition sailed in 1815 under Captain Kotzebue; and after a successful voyage, returned in 1818. Chamisso, in 1821, gave an account of this voyage in a quarto volume entitled *Observations and Discoveries made during a Voyage round the World*—a work that is replete with interesting information, and which established his reputation as a naturalist. Soon after his return he was appointed inspector of the botanic garden at Berlin; and in 1827 he published his *Survey of the Plants of the North of Germany, profitable, useful, or poisonous, together with a View of the Vegetable Kingdom, and of Plants in general.* During the last ten years of his life, he gave proofs of the versatility of his genius in the publication of several tales and poems, which entitle the name of Chamisso to a high place in this field of German literature. He died at Berlin August 12, 1838. (T.S.T.)

CHAMOIS, or Chamois Goat. See Mammalia.

CHAMOMILE, the popular name of the *Anthemis nobilis*, a bitter plant used in medicine, especially the flowers.

CHAMOND, St, a flourishing and well-built town of France, department of Loire, in a fine valley at the confluence of the Gier and Ban, on the railway from St Etienne to Lyons, 8 miles E. by N. of the former. It has a fine church, public baths, and several good buildings; manufactures of cotton and silk fabrics, ribbons, and laces; and considerable cast-iron and nail works. Pop. 9000.

CHAMOUNY, or Chamonix, a celebrated valley of Savoy, province of Faucigny, bounded on the S. and E. by Mont Blanc and others of the Pennine Alps, and on the W. and N. by Mont Breven and the *Aiguilles Rouges.* It is 12 miles in length from N.E. to S.W., with an average breadth of 2 miles, and forms the upper part of the basin of the Arve, which traverses its entire length. This valley is the most celebrated in the Alps for the picturesque grandeur of its mountains and its glaciers, among which is the Mer de Glace, the most remarkable of the Alpine glaciers. The inhabitants of the valley, which is much frequented by travellers, amount to about 3000; the soil is not fertile, but is well cultivated. The climate in winter is severe. The principal village is *La Chamounix* or *La Prieuré*, on the right bank of the Arve, and 3420 feet above the level of the sea.

CHAMPAGNE, an old province of France, now forming the four departments of Ardennes, Marne, Aube, and H. Marne, and part of those of Yonne, Aisne, Seine-et-Marne, and Meuse. Its capital was Troyes, and it was governed by native princes till 1284, when Philippe le Bel united it to the crown of France by marrying Jeanne, Queen of Navarre and Countess of Champagne.

Champagne, *Philippe de* (1602–1674), a celebrated painter, was born at Brussels. He was a pupil of Fouquier, and was employed by Du Chesne to paint along with Nicholas Poussin in the palace of the Luxembourg. His best works are to be found at Vincennes, and in the church of the Carmelites at Paris.

CHAMPAIN, or *Point Champain*, in *Heraldry*, a mark of dishonour in the coat of arms of him who has killed a prisoner of war after he has asked for quarter.

CHAMPION, a person who undertakes a combat in the place or cause of another; and sometimes it denotes one who fights a duel in his own cause. Champions properly were persons who fought instead of those who by custom were obliged to accept the duel, but had a just excuse for dispensing with it, as being too old or infirm, &c. Such causes as could not be decided by the course of common law were often tried by single combat; and the victor was always reputed to have justice on his side. Trial by wager of battle was suppressed by St Louis in 1270.

Champion *of the King*, an officer whose duty it is at the coronation of the English kings to ride armed *cap-à-pie* into Westminster Hall, while the king is banqueting there, and by the proclamation of a herald to make a challenge, "that if any man shall deny the king's title to the crown, he is there ready to defend it in single combat;" after which the king drinks to him, and sends him a gilt cup full of wine, which the champion drinks, retaining the cup as his fee. This office at the coronation of Richard II., when Baldwin Ferville exhibited his petition for it, was adjudged from him to his competitor Sir John Dymocke, both claiming descent from Marmion; and it has continued ever since in the family of the Dymockes, who hold the manor of Scrivelsby in Lincolnshire hereditary from the Marmions by grand serjeantry, namely that the lord of the manor shall be the champion of the king. At the coronation of George IV. in 1821, W. Dymocke being in orders, his place was supplied by his eldest son.

CHAMPLAIN, a considerable lake of North America, lying between the states of New York and Vermont, and

penetrating for a few miles into Canada. It is 140 miles in length, and from 1 to 10 in breadth, lying nearly north and south; and contains a great number of small islands, most of which belong to Vermont. The Champlain canal, 63 miles in length, connects it with the Hudson, and large steamboats and vessels of 100 tons navigate the lake from end to end. The scenery along its shores is highly picturesque, and its waters abound in salmon, salmon-trout, sturgeon, and other fish. See CANADA.

CHAMPOLLION, JEAN FRANÇOIS LE JEUNE, so called to distinguish him from Champollion Figeac, his elder brother, was born at Figeac, department Du Lot, in 1796. He was educated at Grenoble, and afterwards at Paris, where under Langlès and De Lacy he devoted himself to the study of Coptic. In 1811 he was made professor of history in the Lyceum of Grenoble, and there published his earlier works. He was sent by Charles X. in 1824, to visit the collections of Egyptian antiquities in the museums of Turin, Leghorn, Rome, and Naples; and on his return was appointed director of the Egyptian museum at the Louvre. In 1828 he was commissioned to undertake the conduct of a scientific expedition to Egypt, and accompanied Rosellini, who had received a similar appointment from Leopold II. Grand Duke of Tuscany. He remained there about a year; and soon after his return was appointed professor of Egyptian Antiquities in the Royal College at Paris. He was engaged along with Rosellini in publishing the results of his Egyptian researches at the expense of the Tuscan and French governments, when he was seized with a paralytic disorder, and died at Paris in 1831. For an account and estimate of his discoveries, see HIEROGLYPHICS and EGYPT.

He wrote *L'Egypte sous les Pharaons*, 2 vols. 8vo, 1814; *De l'Ecriture Hiératique des Anciens Egyptiens*, 1821; *Précis du Système Hiéroglyphique, &c.*, 1824; *Panthéon Egyptien, ou Collection des Personages Mythologiques de l'Ancienne Egypte*, incomplete; *Monumens de l'Egypte et de la Nubie considérés par rapport à l'Histoire, la Religion, &c.*; *Grammaire Egyptienne*, 1836, edited by his brother; and also several letters on Egyptian subjects, written at different periods to his patrons.

CHANCAY, a town of Peru, capital of a province of the same name in the department of Lima, situated in a beautiful valley, a few miles from the river Passamayo, and 40 miles N.W. of Lima. It has a tolerable port, well frequented by small trading vessels. Pop. 2000.

CHANCE, a term applied to an event that happens without being contrived, expected, or foreseen. In other words, it is the effect of an unknown, or the unexpected effect of a known cause. Those things are frequently ascribed to *chance* which do not seem necessarily to follow as the natural effects of any adequate cause; but through ignorance or precipitancy, effects proceeding from a determinate cause are often attributed to chance. The term *chance*, as commonly used, really means nothing more than that the cause of the event is unknown; not, as some have imagined, that an event can happen without a cause. The case of the painter who, in despair at his inability to express the foam at the mouth of a horse he had painted, threw his sponge at the picture and did that *by chance* which he could not before do by design, is an eminent instance of the common meaning of the term; since he did not fore-calculate the result, nor throw the sponge with a view to produce it.

Chance is frequently personified, and then corresponds to the *Fortuna* of the ancients. Chance is also used for the manner of deciding things, the direction of which is not reducible to any determinate rules, or where there is no ground for preference, as at cards, dice, lotteries, and the like. The doctrine of chances is discussed under the head PROBABILITY.

The ancient *sortilege* or *chance* was of divine origin, since in the Old Testament we find several standing laws and express commands which prescribed its use on certain occasions. We read in the Acts—"the *lot* fell upon Matthias," when it was in question who should fill Judas's place in the apostolate; and hence also arose the *sortes sanctorum*, or method of solving difficulties among the ancient Christians, by opening some of the sacred books, and regarding the first verse that arrested the eye as a prognostic. The *sortes Homericæ, Virgilianæ, Prænestinæ*, and the like, used by the heathens, were of a similar kind. St Augustin seems to approve of this method of determining things future, and even admits that he had practised it, justifying his doing so on the ground that God presides over *chance*.

CHANCEL, that part of the choir of a church between the altar or communion-table and the balustrade or rail that incloses it, or that part where the altar is placed. The word is derived from the post-classical Latin *cancellus*, from *cancelli*, lattices or cross-bars, with which the chancels were anciently encompassed, as they now are with rails. It corresponds with the *bema* of the ancient basilica, and is generally represented by the apsis in romanesque and early pointed architecture. In Britain the possession of a chancel in some shape or other is generally the distinction of a Romish or Episcopal from a Presbyterian church. In England, the right to the chief pew in the chancel is one of the privileges which belong to the rector or impropriator, but he is not entitled as of right to make a vault, or affix tablets in the chancel without leave of the ordinary.

CHANCELLOR. Various origins have been attributed to this word, so important in its modern use over the greater part of the civilized world; and all of them are of a trivial nature, bearing little reference to the subsequent application of the term. The preceding word *chancel* is connected with the most ordinary and apt of these origins. It supposes the chancellor to have been so called because he sat within a lattice or screen partitioned from the court of justice or hall of audience. There was no such office in the early civil law, and even under the later western emperors the cancellarius appears to have been a mere subordinate person, a sort of clerk of the chamber, or scribe, who saw the petitioners, and arranged about their business. Gradually he appears to have risen to the rank of an adviser or conscience keeper, on whose decision the fate of suitors in a great measure depended. In the eastern empire the chief cancellarius had become a powerful and important officer. As it was the principle of the popedom to be the spiritual counterpart of the empire, and possess a corresponding hierarchy, the office was imitated at the ecclesiastical court of Rome, and a chancery at the Vatican was repeated throughout the several bishoprics, where each diocese had its chancellor. The great monastic houses too had frequently a chancellor. In the universities, an officer of the same name was the connecting link between their republican institutions and the Romish hierarchy. While the rector was elected by the proctors of the nation, or some other corporate constituency, the bishop of the diocese, or in some cases the head of the monastic house to which the university was subordinated, was *ex officio* the chancellor.

It was the ambition of the kings who rose on the fall of the Roman empire, even of those who reigned in Saxon England, to gather round them as many as they could obtain of the attributes of the emperor or basileus, and hence each generally had his cancellarius. In central Europe the office would naturally descend from the imperial court of Charlemagne; and in France the chancellor became the head of the law and the minister of justice. The office was abolished at the first revolution. At the restoration the ministry of justice was made a separate office, and the chief function of the chancellor was to preside in the House of Peers.

It is perhaps in England that we have the most remarkable illustration of the struggle between the influence of the imperial usages and the constitutional spirit of the northern nations. The existence of common law courts

Chancellor. enforcing in its strictness what was deemed the old law of the land, and the chancery with its regal equity interfering to give redress, just presents to us the English people with their common lawyers standing for their rights and privileges, and the monarch, with his clerical advisers, endeavouring to acquire the imperial prerogatives. The chancellor was generally a churchman, who took his ideas of law from the canonists and the civilians, whose principles were intensely disliked by the common lawyers. Hence the two systems called law and equity grew up in antagonism, neither throughout a long contest being able to conquer the other; and hence it is that England has been burdened with the inconvenience of having two systems of jurisprudence, the one called common law, the other equity. The spirit of the former, indeed, may be said to have been so far triumphant, in compelling equity to depart from her digressional vagueness, and become a fixed system as securely bound to statute and precedent as the common law itself. But even in Selden's day we find the laxity of the chancellor's equity so much suspected, that he says in his *Table Talk*, "Equity is a roguish thing. For law we have a measure—know what to trust to: equity is according to the conscience of him that is chancellor, and as that is larger or narrower, so is equity. It is all one as if they should make the standard for the measure we call a foot, a chancellor's foot. What an uncertain measure would this be! One chancellor has a long foot, another a short foot, another an indifferent foot; it is the same thing in the chancellor's conscience." How little, indeed, the chancery practice had been at that time moulded into a strict system, we may infer from the seals being held by a churchman, the celebrated Archbishop Williams, and this at the time when the common law had accumulated that amazing mass of intricate precedents which it tasked all the diligence and genius of Coke to reduce into order. Clarendon, when he became chancellor, had been twenty years out of practice, and his successor Shaftesbury had no pretensions to be acquainted with law. Lord Nottingham appears to have been the first who wished to apply strict rules in the court of chancery, but it does not seem to have been in a fit condition for their application. Roger North says, "he was a formalist; and took pleasure in hearing and deciding, and gave way to all kinds of motions the counsel would offer; supposing that if he split the hair, and with his gold scales determined reasonably on one side of the motion, justice was nicely done—not imagining what torment the people endured who were drawn from the law, and there tost in a blanket." (*Life of Lord Keeper Guildford*, 423.) Guildford himself, who, in the words of Lord Campbell, "had as much law as he could contain," made light of the mere judicial business of his office, which ere then, however, had begun to show its characteristic defects, for according to his biographer, "the greatest pain he endured ensued from a sense he had of the torments the suitors underwent by the excessive charges and delays of the court."

The lord high chancellor of Great Britain is a great state officer, with varied and disconnected functions. He is in official rank the highest civil subject in the land out of the royal family, and when raised to the peerage, as he invariably is, he takes precedence immediately after the archbishop of Canterbury. His functions have sometimes been exercised by a "lord keeper of the great seal;" but there appears to be no essential differences between the two offices, save that the keeper is appointed by mere delivery of the seal, which is of itself sufficient to confer all the powers appertaining to the office, while a chancellor receives letters patent along with it. As a great officer of state, the chancellor acts for both England and Scotland, and in some respects for the United Kingdom, including Ireland. As an administrative officer, as a judge, and as head of the law, he acts merely for England. In the first class of functions, he acts as prolocutor, speaker, or chairman of the House of Lords, and in this capacity it sometimes falls to him to adjudicate in Scottish law, since he often leads the judgment of the house on appeals. (See APPEAL.) By the Treaty of Union, one great seal was appointed to be kept for all public acts. Hence, in this department, the chancellor's authority extends to the whole of Britain, and thus the commissions of the peace for Scotland as well as England issue from him. His English ministerial functions are thus briefly described by Blackstone:—"He became keeper of the king's conscience, visitor, in right of the king, of all hospitals and colleges of the king's foundation; and patron of all the king's livings under the value of twenty marks per annum, in the king's books. He is the general guardian of all infants, idiots, and lunatics; and has the general superintendence of all charitable uses in the kingdom." There is much convenience in the repetition of such vague definitions, from the difficulty of more specifically defining the chancellor's functions in these matters. His indistinct and unsatisfactory authority as to charitable foundations has been virtually superseded by the Charity Commissioners' Act of 1853 (17th Vict., cap. 137). The lord chancellor is by office a privy-councillor, and it has long been the practice to make him a cabinet minister. Hence he belongs to a political party, and is affected by its fluctuations. This has often been denounced as destructive of the independence and calm deliberativeness essential to the purity and efficiency of the bench. In defence, however, of the ministerial connection of the chancellor, it has been said, that while the other judges should be permanent, the head of the law should stand or fall with the ministry, as the best means of securing his effective responsibility to parliament for the proper use of his extensive powers. The late addition of permanent judges to the chancery court has removed many of the objections to the fluctuating character of the office.

In Ireland, there is a lord chancellor at the head of the equity system, which arose in minute imitation of the English. He is generally raised to the peerage.

In Scotland, a chancellor appears at a pretty early period in history, as the person who, being the adviser and conscience-keeper of the king, issued his writs or letters for the remedy of injustice done by judges or other persons in power. A comparison between the English and the Scottish chancellor of the thirteenth century would probably show them to have then been much alike. Subsequently, however, the civil law predominating in Scotland, the chancellor was its chief administrator, instead of leading on a system antagonistic to the common law. Hence he became the leading judge of the Court of Session on its establishment in 1533. While Episcopacy predominated he was generally an ecclesiastic, never a working lawyer; and after the revolution he became an officer of state, who was not expected to be a working lawyer. Hence, when by the Treaty of Union the great seal for public transactions was appointed to be kept in England, the lord chancellor of Scotland dropped out of existence. A keeper of the great seal continued to be appointed for sealing writs as to private matters, and the office of director of chancery remained for the transaction of routine business connected with the department. When the method of certifying hereditary successions was simplified and placed on a uniform system in 1848, it was put under the direction of an officer called the sheriff of chancery. (J.H.B.)

CHANCELLOR *of a Cathedral*, an officer who holds the courts of the bishop, and acts as his assessor or adviser in matters of ecclesiastical law. He also inspects schools, applies the seal, writes and despatches letters of the chapter, keeps the books, &c.

CHANCELLOR *of the Duchy of Lancaster*, an officer appointed of old chiefly to determine controversies between the king and his tenants of the duchy land, and otherwise to direct all the king's affairs belonging to that court. By late

practice, the office was nominally one of high dignity, but, demanding little exertion, has been given to statesmen who have grown old in other and more laborious offices, but whose services are still desired in the ministry.

CHANCELLOR *of the Exchequer*, an officer who, according to the old definitions of his functions, presides in the exchequer court, and takes care of the interest of the crown. He is always in commission with the lord treasurer for the letting of crown lands, &c., and has power, with others, to compound for forfeitures of lands upon penal statutes. While the treasury is understood to have the custody and distribution of the collected revenue, it is the function of the exchequer to realize it. Hence the chancellor of the exchequer, as the head of that department which proposes to parliament the plans for the annual revenue, and sees to its realization, is always an important member of the cabinet. Sometimes he is prime minister. His annual statement of the method by which he proposes to meet the exigencies of the exchequer, called "The Budget," is always received with great interest by parliament and the public.

CHANCELLOR *of the order of the Garter and other military orders*, an officer who seals the commissions and mandates of the chapter and assembly of the knights, keeps the register of their proceedings, and delivers their acts under the seal of their order.

CHANCELLOR *of a University*, an officer who seals the diplomas, or letters of degrees, &c. The chancellors of the universities of Oxford, Cambridge, and London, are elected by the respective corporate bodies of which they are the heads. Their duties, however, are usually discharged by the vice-chancellors. Each of the Scottish universities, likewise, with the exception of that of Edinburgh, has a chancellor elected by the senatus.

CHANCERY, the name of the highest court of justice in England and Ireland. Of its origin an account has been given under the head CHANCELLOR. In chancery there are two distinct tribunals; the one ordinary, being a court of common law; and the other extraordinary, being a court of equity.

1. The *ordinary* legal court has been accustomed to hold pleas of recognizances acknowledged in the chancery, writs of *scire facias* for repeal of letters patent, of partition of lands in coparcenary, &c., and (until the 12th and 13th Vict., cap. 109, sec. 42) of all personal actions by or against any officer of the court. Sometimes a *supersedeas*, or writ of privilege, has been granted by this court, to discharge a person out of prison: one may also obtain here a *habeas corpus* prohibition, &c. in the vacation; and a *subpœna* may be had to force witnesses to appear in other courts when they have no power to call them. If the parties to a cause are at issue in a matter of fact, this court cannot try it by jury. A transcript of the record is sent to one of the superior courts of common law (see 12th and 13th Vict., cap. 109, sec. 32), to be tried there; and after trial it is remanded into the chancery, where judgment is given. If there be a demurrer in law, it must be argued in this court. Under the 15th and 16th Vict., cap. 86, sec. 61, however, the court of chancery can no longer direct a case to be stated for the opinion of any court of common law, but it may determine any questions of law in its judgment necessary to be decided previously to the decision of the equitable question at issue. Under sec. 62, it is now no longer necessary to establish at law the legal title or right of the party seeking relief before equitable relief is granted; while in cases of difficulty, the attendance of a common law judge is procured to hear the case with the equity judge.

In this court is also kept the *officina justitiæ*, out of which all original writs that pass under the great seal, all commissions of charitable uses, sewers, idiotcy, lunacy, and the like, issue; and for which it is always open to the subject, who may there at any time demand and have, *ex debito justitiæ*, any writ which his occasions may call for. Those writs relating to the business of the subject, and the returns to them, were, according to the simplicity of ancient times, originally kept in a hamper, *in hanaperio;* and the other (relating to such matters wherein the crown was mediately or immediately concerned) were preserved in a little sack or bag, *in parva baga;* and hence has arisen the distinction of the *hanaper* office and the *petty-bag* office, which both belong to the common law court in chancery.

2. The *extraordinary* court, or court of equity, had its origin in those arrangements avowedly designed for affording relief against the rigour of the common law, which have been noticed under the head CHANCELLOR. It gives relief for and against infants notwithstanding their minority, and for or against married women notwithstanding their coverture. All frauds and deceits for which there is no redress at common law; all breaches of trust and confidence; and unavoidable casualties by which obligors, mortgagors, and others, may be held to incur penalties and forfeitures, are here remedied. This court also gives relief against the extremity of unreasonable engagements entered into without consideration; obliges creditors who are unreasonable to compound with an unfortunate debtor; and makes executors, &c. give security and pay interest for money which is to lie long in their hands. This court may confirm the title to lands, though one has lost his writings; and render conveyances which are defective through mistake or otherwise, good and perfect. In chancery, copy-holders may be relieved against the ill usage of their lords; inclosures of land which is common may be decreed; and this court may decree money or lands given to charitable uses, oblige men to account with each other, &c. But in all cases where the plaintiff can have his remedy at law, he ought not to be relieved in chancery.

The court of chancery, proverbial for the intricacy and tediousness of its procedure, has lately been the object of repeated legislative reforms, far too technical in their character to be indicated in a sketch like the present. From an early period the equity jurisdiction was shared by the master of the rolls, who was the chief of a body of officers called masters in chancery. These officers, who have been in use of late to exercise important ministerial functions, were in the sixteenth century doctors of the civil law. After many alterations in their functions, they were in 1852 (15th and 16th Vict., cap. 80) prospectively abolished with reservation of the rights, duties, and privileges of the accountant-general as master in chancery. In 1813, there was appointed an additional judge in chancery by the title of vice-chancellor of England; and on the transference to this court of the equity business of the Exchequer in 1841, two additional vice-chancellors were appointed. By an act of 1851 "to improve the administration of justice in the court of chancery, and in the judicial committee of the privy-council," an addition was made of two judges to be called "judges of the court of appeal in chancery." This is a court of appeal from the master of the rolls and the vice-chancellors. Its jurisdiction may be exercised by the two judges of appeal, either with or without the lord chancellor, by the lord chancellor and one of the judges, or by the lord chancellor alone, as of old. The act thus enables the highest judicial functions of the lord chancellor to be distributed among other functionaries, with this peculiarity, that *he* can exercise them alone, but the two new judges must act together. The court is vested with all the powers exercised by the lord chancellor "in the court of chancery," "and all powers, authorities, and duties, as well ministerial as judicial, incident to such jurisdiction;" but there is a special exception of the ministerial and other duties not exercised in the court of chancery.

CHANDERNAGORE, a French settlement in Bengal, in a healthy situation on the western bank of the Hooghly river. It is about three quarters of a mile long, and is surrounded by a small territory, consisting of 2330 acres, with

a population of 32,670, of whom 218 are Europeans, 435 of mixed descent, and the remainder of native lineage. The authorities of Chandernagore are subject to the jurisdiction of the governor of Pondicherry, to whom is confided the general government of the French possessions in India. The town has an air of ruined greatness, its fine streets and noble quay being now overgrown with grass. The height of the houses is usually two stories: they have colonnades in front, and green Venetian windows, and are built of brick and mortar, plastered over with fine chunam, both inside and out. They have generally flat roofs, on which their proprietors sit in the evening and receive company. The French having obtained this situation for their factory in 1676, they afterwards fortified it, and the factory continued to flourish till the year 1757, when it was attacked by Admiral Watson and Colonel Clive, who, having forced it to surrender, dismantled its fortifications. France recovered Chandernagore under the treaty of 1763. It was again occupied by the British in 1793 upon the breaking out of the republican war, but finally restored to the French at the general pacification in 1816. Distance north from Calcutta 17 miles. N. Lat. 22. 49.; E. Long. 88. 23.

CHANDLER, Richard, D.D., one of the most learned and judicious of British travellers during the last century, was born in 1738 at Elson in Hampshire, educated at Winchester school, and subsequently at Queen's College, Oxford. His early publication of fragments from minor Greek poets, with notes, in 1759, showed his fine literary taste; and his splendid edition of the Arundelian marbles, *Marmora Oxoniensia*, in 1763, with the accurate transcript of the venerable original, his good Latin translation, and judicious conjectures in supplying the lacunæ, established his reputation as a scholar and an antiquary.

In 1763 Chandler was sent, with Revett the architect, and Pars a painter, by the Dilettanti Society of England, to explore the antiquities of Ionia and Greece. After spending above a year in Asia Minor, the travellers passed another year in Greece examining Attica and the Peloponnesus, and returned to England in the end of 1766. The result of their joint investigations were the two magnificent folios of Ionian antiquities published in 1769. Chandler published a very valuable collection of inscriptions, entitled *Inscriptiones Antiquæ pleræque nondum editæ; in Asia Minore et Græcia præsertim Athenis collectæ*, in a folio volume, at Oxford in 1774. In 1775 he published his *Travels in Asia Minor*, and in 1776 his *Travels in Greece*, each in a quarto volume; which have not been surpassed by those of any subsequent traveller. Octavo editions of both, with a memoir of the learned author, appeared in 1835. Dr Chandler married in 1786, and soon after travelled in Switzerland and Italy. In 1800 he obtained the rectory of Tylehurst in Berkshire, in addition to church preferment which he held in Hampshire. He died in Feb. 1810. His posthumous Life of Bishop Waynflete, Lord High Chancellor to Henry VI., was published in 1811. (T. S. T.)

Chandler, *Dr Samuel*, a learned Dissenting minister, was born in 1693, at Hungerford, Berkshire, where his father was an eminent nonconformist minister. In an academy at Gloucester, conducted by Mr Samuel Jones, he contracted a friendship with Butler, afterwards bishop of Durham, and Secker, afterwards archbishop of Canterbury, which continued to the end of their lives.

Mr Chandler began to preach about July 1714; and being soon distinguished by his talents in the pulpit, was chosen in 1716 minister of the Presbyterian congregation at Peckham. Here he married; but having lost, by the fatal South Sea scheme, the whole of his wife's fortune, he was compelled to open a book shop in the Poultry, which he kept for two or three years, still continuing to discharge his pastoral duties. He also held, alternately with Dr Lardner, a winter weekly evening lecture at the meeting-house in the Old Jewry; where he was first settled as assistant preacher, and then as pastor. Here, for forty years, he ministered to a very respectable congregation with great success; and devoted the intervals of leisure to writing on a variety of important subjects. While he was thus employed, the universities of Edinburgh and Aberdeen conferred on him the degree of doctor in divinity, and he received offers of high preferment in the Established church, which he nobly declined. He had likewise the honour of being elected fellow of the Royal and Antiquarian Societies.

On the death of George II. in 1760, Dr Chandler published a sermon on that event, in which he compared King George to King David. This called forth a pamphlet entitled *The History of the Man after God's own Heart;* in which the author—resuscitating the article of Bayle—exhibited king David as an example of perfidy, lust, and cruelty; and complained of the insult offered to the memory of the late British monarch by Dr Chandler's parallel. This attack determined Dr Chandler to publish an immediate reply in the following year; and also to prepare a more elaborate work, which was afterwards published in two volumes 8vo, entitled *A Critical History of the Life of David, &c.;* refuting the objections of Bayle, and satisfactorily expounding his penitential psalms. This, the last and perhaps the best of Dr Chandler's productions, had been printed off just before the author's death, which took place May 8, 1766.

Dr Chandler was a man of very extensive learning and eminent abilities; and his talents, both in the pulpit and as a writer, procured him very great and general esteem.

In 1768 four volumes of his sermons were published by Dr Amory, according to his own directions in his last will. In 1777 another work of his was published in one volume 4to:—*A Paraphrase and Notes on the Epistles of St Paul to the Galatians and Ephesians, with doctrinal and practical Observations; together with a critical and practical Commentary on the two Epistles of St Paul to the Thessalonians.*

CHANG Chau, a town of China, province of Fo-Kien, on a river, 35 miles W. of Amoy. It is said to be well built, with streets paved with granite, but very dirty. A wooden bridge, about 800 feet long, spans the river. Pop. said to be about 800,000.

CHANNING, William Ellery, was the son of William Channing and Lucy Ellery, and was born at Newport, Rhode Island, on the 7th of April 1780. The place of his birth is situated amidst scenery of great and varied beauty; the influence of which upon his mind may be traced in many allusions in his writings, and in the vivid admiration which he ever expressed for it in after-life. To the society of the town of Newport he owed but little; it was a bustling, crowded seaport, where a certain Puritanic strictness, inherited by tradition from the founders of the state, was kept up, not only in connection with, but too much as a salvo for, a considerable amount of laxity both of speech and practice. As a bathing place it was a resort for strangers from other parts; and the interfusion of French and British officers tended to modify the peculiarities which the unmixed influence of retired sea captains, West Indian traders, and keen New England lawyers, might have rendered too strong.

As a child, Channing was remarkable for a refined delicacy of feature and temperament, which made him an object of admiration and affection in the household. From his father he inherited a fine person, simple and elegant tastes, sweetness of temper, and warmth of affection; from his mother (who appears to have been a remarkable woman) he derived the higher benefits of that strong moral discernment and straightforward rectitude of purpose and action which formed so striking a feature of his character. By both parents he was carefully instructed in those strict religious principles which were characteristic of the people of New England; and by both, but especially his mother, was his moral training most sedulously cared for. Other influences, however, were in the meantime operating upon him. The

excitement of the revolutionary war was inspiring him with a profound and ardent love of freedom. The sick chamber of an aunt of his father, who was a woman of much piety and sweetness, was the source of many serious and hallowed lessons of gentleness and goodness. An amateur Baptist preacher, who was by trade a cooper, gave him an impulse which he never lost in favour of temperance, by refusing, though very poor, to manufacture any of the articles of his trade used for containing ardent spirits. A female servant, whose religious views were of a more cheerful cast than those prevalent in his circle, used to talk to him in a way that greatly engaged him, and probably sowed the germ of not a few of the ideas which afterwards regulated his modes of religious sentiment. Able and free-minded men, like Dr Stiles and Dr Hopkins, frequented his father's house, and the quiet and thoughtful boy listened to their conversations, and laid many suggestive words that fell from them to heart. And while but a child he had begun to draw inferences from what he heard from the pulpit and elsewhere that were not quite such as his guardians would have wished him to draw; and he "was even then quite a theologian, and would chop logic with his elders according to the fashion of that controversial time," as he himself tells us.

Whilst very young, he was sent to a dame's school, who exacted from the incipient republicans the title of *Madam*, and enforced her authority and her lessons by means of "a long round stick." From this he passed under the care of two excellent women, by whose instructions he profited greatly. His next step was to the school of a Mr Rogers, considered the best at that time in the town; and in his twelfth year he was sent to New London to prepare for college, under the care of his uncle the Rev. Henry Channing. His career at school does not appear to have been marked by any remarkable aptitude for letters; on the contrary, his progress was at first somewhat slow; though, after the few initiatory difficulties were overcome, he advanced rapidly, both in a knowledge of the classics and an appreciation of their excellences. His disposition was thoughtful and retiring, though among his companions he showed no absence of relish for lively conversation or hearty amusement. A certain mingled dignity and sweetness gave him a commanding influence in the school, where he went by the name of "the Peacemaker," and "Little King Pipin," and where he was obeyed, though "small and delicate," with more readiness than mere physical strength could ever have commanded.

Shortly after going to reside with his uncle, his father died. This event, however, though it produced a great change in the circumstances of the family, was not allowed to interrupt the course of his studies. After the funeral he returned to the house of his uncle, where he remained till he had reached his fifteenth year, when he was removed to Cambridge, Massachusetts, and entered at Harvard College as freshman in 1794. Before leaving New London he came under the influence of a religious revival which took place there, a circumstance to which he was accustomed to trace the commencement of a decidedly religious life.

The four years he remained at college seem to have been most profitably spent. Besides acquiring an extensive acquaintance with classical and general literature, he read largely and thought earnestly in the department of psychology and ethics. The books which appear to have exerted most influence upon his mind and opinions were Price's Dissertations, Hutcheson on Beauty and Virtue, and Ferguson on Civil Society. To the study of Shakspeare also (the interest in whose works was then newly awakened in that quarter) he owed much; and so deep was the impression made on him by the genius of the poet, that to the close of his life one of the greatest of his intellectual treats was furnished by recitations from his writings. By patient and well-directed assiduity he trained himself to the mastery of that copious and vigorous style of composition to which his subsequent position in the world of letters is in no small measure due; and at the same time also laid the basis of his success as a public speaker, by the formal study of rhetoric, and by frequent practice in addressing assemblies of his fellow-students.

For a year and a half after leaving college in 1798, Channing was resident at Richmond, in Virginia, as tutor in the family of David Meade Randolph, Esq. Here he had time for study, which he employed chiefly on theological subjects. In regard to many points, touching both the evidences of Christianity and its doctrines, his mind was burdened with doubt and anxiety; and so earnestly did he labour to attain satisfaction, that his constitution sank under the incessant toil. When, in 1800, he returned to Newport, his friends were shocked to find him changed to "a thin and pallid invalid;" and unhappily, at this time were sown the seeds of that depressed condition of health which continued through life his severest trial. He remained in the bosom of his family for another year and a half, engaged in the pursuit of his studies, and in preparing himself, by physical and moral as well as intellectual training, for the work to which he was looking forward—that of the ministry. In 1802 he returned to Cambridge, having been elected to the office of regent in Harvard University; a situation which, without exacting from him any large amount of service, secured to him the advantage of independence, and an opportunity of prosecuting his studies within reach of a valuable library, and under influences favourable to success. In the autumn of 1802 he began to preach, having received approbation to do so from the Cambridge Association; and in the beginning of the following year he accepted the invitation of the Congregational church, Federal Street, Boston, to be their pastor. To this office he was ordained in June 1803.

Channing entered on his ministry with a deep and almost painful sense of the responsibility of the office he had assumed, and with an earnest desire to acquit himself faithfully of its obligations. His theological views were at this time considered orthodox; at least they presented no marked deflection from the standard of moderate Calvinism. In a sermon which he preached at the ordination of the Rev. J. Codman, in 1808, and which constitutes, we believe, his earliest publication, the language and sentiments are in all respects such as any evangelical divine might use. Now, as at all times, however, he refused to be inclosed within the limits of party, and acted with an indiscriminateness in his religious associations, which led to his being alternately claimed and disowned by almost every party, and which indicates that no very high importance was attached by him to differences of creed. It was not till controversy evolved into distinctness the latent tendencies of his mind in the matter of theological speculation, that it became manifest that he was irreconcilably at variance with rigid Calvinism and Trinitarianism. From the year 1815 he may be regarded as nominally a Unitarian. This, however, was not then, and never became, the Unitarianism which in this country, in the hands of Priestley and Belsham, so dogmatically asserted the mere humanity of Jesus Christ. From this Channing ever held himself aloof. "I am little of a Unitarian," he wrote in 1841; "have little sympathy with the system of Priestley and Belsham; and stand aloof from all but those who strive and pray for clearer light." It was rather an exaggerated view of the worth and dignity of man, and a sensitive dread of anything which might lead to a "gloomy theology," than a clear and firm adoption of the system of Socinus, which induced him to deny the doctrine of the trinity and the doctrines with which it stands associated in the Bible. So far, indeed, as we can judge from his writings, the question, as one of Biblical interpretation, had very little exercised his thoughts. His belief on this head was more the dictate of a sentimental theosophy, than the result of earnest and discriminating inquiry.

In 1814 Channing married his cousin, Ruth Gibbs; a union which brought him an increase of worldly substance, as well as a rich addition to his personal happiness. "Inwardly and outwardly," his biographer tells us, "his lot henceforward was singularly serene." He was now fast rising in reputation, both as a preacher and a public man. Interested in all that concerned his country and the cause of humanity, his voice was heard on most of the questions that came before the American public, and always with marked and growing effect. He had begun also to command attention as a writer for the press. His Address on War, some of his Sermons, and especially his able tract on the Evidences of Christianity, had given him a position of eminence among the writers of his country. In 1821 he received the title of D.D. from Harvard University. In 1822 he undertook a journey to Europe, in the course of which he visited Great Britain and some parts of the Continent. When in this country, he made the acquaintance of some distinguished men of letters, especially Wordsworth and Coleridge, on both of whom he appears to have left a most favourable impression. Coleridge wrote of him, "He has the love of wisdom and the wisdom of love." On his return, Dr Channing resumed his duties as a minister, but with a more decided attention than before to literature and public affairs. In 1824 he received as colleague the Rev. Ezra Stiles Gannett, at whose ordination he preached one of his published discourses. From this time forward his energies were devoted, in addition to his pulpit labours, chiefly to the furtherance of great schemes of social reform. Of the antislavery cause he was throughout the firm, eloquent, and uncompromising advocate; and in every question that bore upon the happiness of the people he took a lively interest. Of his publications, the most extensively read are his *Remarks on the Life and Character of Napoleon Bonaparte*, his *Remarks on the Character and Writings of John Milton*, his *Essay on the Character and Writings of Fénélon*, and his *Essay on the Importance and Means of a National Literature*. He died in the sixty-third year of his age, on Sunday, the 2d of October 1842, whilst on a journey, at Bennington, Vermont; and was buried at Boston, on the 7th of that month. An extended memoir of him has been published by his nephew, Wm. Henry Channing, 3 vols., London, 1848. (W. L. A.)

CHANT (*cantus*) is used for the vocal music of churches. In church history we meet with divers kinds of *chants* or *songs*. The first is the *Ambrosian*, established by St Ambrose; the second is the *Gregorian*, introduced by Pope Gregory the Great, who established schools of chanters, and corrected the church song. This, which is still retained in the church under the name of *plain song*, at first was called the *Roman song*. The *plain* or *Gregorian chant* is sung by the choir and people in unison.

CHANTIBAN, a large inland town of Siam, capital of a province of the same name, on the south bank of a river near its mouth in the Gulf of Siam, 150 miles S.E. of Bangkok. It has a considerable trade, exporting pepper, cardamoms, rosewood, dyewoods, ship timber, hides, horns, ivory, &c.; and in the vicinity are mines of precious stones.

CHANTILLY, a small village on the Nouette, department of Oise, France, 24 miles north of Amiens. It is famous for its manufacture of blonde, which is still extensively carried on, but derives its principal celebrity from the *Grand Château*, which was the residence of the Prince of Conde. The main building was destroyed during the revolution, but the Petit Chateau and the gardens still remain. The body of Admiral Coligny was buried in the parish church here after the massacre of St Bartholomew. It contains a famous hospital, built and endowed by the Prince of Conde.

CHANTREY, Sir Francis, a celebrated sculptor, was born in 1782, at Norton, near Sheffield, where his father cultivated a small property of his own. His father died when he was eight years of age; and his mother having married again, his profession was left to be chosen by his friends. In his sixteenth year he was on the point of being apprenticed to a lawyer in Sheffield, when, having seen some wood-carving in a shop-window, he requested to be made a carver instead of a solicitor, and was accordingly placed with a Mr Ramsay, wood-carver in Sheffield. When in this situation, he became acquainted with Mr Raphael Smith, a distinguished draftsman in crayon, who gave him lessons in painting; and Chantrey, eager to commence his course as an artist, procured the cancelling of his indentures, and went to try his fortune in London. Here he first obtained employment as an assistant wood-carver, but at the same time devoted himself to portrait painting and modelling in clay. His first imaginative work was the model of the head of Satan, which was exhibited at the Royal Academy in 1808. He afterwards executed for Greenwich Hospital four colossal busts of the Admirals Duncan, Howe, Vincent, and Nelson; and so rapidly did his reputation spread that the next bust which he executed, viz. that of Horne Tooke, procured him commissions to the extent of L.12,000. From this period he was almost uninterruptedly engaged in professional labour. In 1819 he visited Italy, and became acquainted with the most distinguished sculptors of Florence and Rome. He was chosen a royal academician, received the degree of A.M. from Cambridge, and that of D.C.L. from Oxford, and in 1835 was knighted by William IV. He died, after an illness of only two hours' duration, on the 25th November 1841, and was buried in a tomb constructed by himself in the church of his native village. The works of Chantrey are far too numerous to receive particular notice. The principal are the statues of George III. at London, of George IV. at Brighton, of Pitt in Hanover Square, of Watt in Westminster Abbey and Glasgow, of Roscoe and Canning at Liverpool, of Dalton at Manchester, &c. He also executed the statues of Blair and Lord Melville in Edinburgh. Of his equestrian statues the most famous are those of Sir Thomas Munro at Calcutta, and the Duke of Wellington in front of the London Exchange. But the finest of all Chantrey's works are his inimitable delineations of children. The figures of two children asleep in each other's arms, which formed a monumental design in Litchfield Cathedral, are unmatched for beauty, simplicity, and grace. So is also the statue of Lady Louisa Russell, represented as standing on tiptoe and fondling a dove in her bosom. Chantrey was a man of warm and genial temperament, and is said to have borne a striking resemblance to the usual portraits of Shakspeare. He bequeathed his valuable collection, and his whole fortune, after the death of Lady Chantrey, to the Royal Academy, for the encouragement of British sculpture and painting.

CHANTRY, or Chauntry, a little chapel or altar, commonly in some church endowed (before the Reformation) with lands or other revenue, for the maintenance of one or more priests, daily to say or sing mass for the souls of the founder and such others as he might appoint. Chantries were dissolved in England by 1st Edw. VI., cap. 14.

CHAOS, that confused mass or state of confusion in which matter is supposed to have existed before it was reduced to order by the creating power of God. The term is taken from the Greek mythology, according to which Chaos was the vacant and infinite space which existed before the creation of the world, and out of which the gods, men, and all things arose. (Hesiod, *Theog.* 116; Ovid, *Met.* i. 5.) The description which Ovid gives of Chaos itself, and of the formation of the world from the chaotic mass, bears so many striking resemblances to the Mosaic account of the creation, that one can scarcely fail to regard it as having been derived from traditions, the source of which is to be traced to the sacred record. See Creation and Geology.

CHAPEAU. See *Cap of Maintenance.*

CHAPEL, a building for religious worship. The word is derived from the Latin *capella.* In former times the kings of France during war always carried St Martin's hat into the field, and kept it in a tent as a precious relic; hence the place was called *capella,* and the priest who had the custody of the tent *capellanus.* From this circumstance the word *capella* came to be applied to private oratories.

In Britain there are several sorts of chapels. 1. Parochial chapels, distinct from the mother church. If there be a presentation *ad ecclesiam* instead of *capellam,* and an admission and institution upon it, it is no longer a chapel, but a church. 2. Chapels which adjoin to and are a part of the church. These were formerly built by honourable persons as private burying-places. 3. Chapels of ease, built in large parishes for the accommodation of the inhabitants. 4. Free chapels, such as were founded by the kings of England, and freed from all episcopal jurisdiction. 5. Chapels in the universities belonging to particular colleges. 6. Domestic chapels, built by noblemen or gentlemen for the use of their families.

The name of Chapel is also given to the body of printers engaged in any establishment, either because printing was first performed in chapels or churches, or because Caxton exercised the art in one of the chapels in Westminster Abbey. Hence *the order or laws of the chapel, the secrets of the chapel,* &c.

Knights of the Chapel, or *Poor Knights of Windsor,* were instituted by Henry VIII. in his testament. Their number was at first thirteen, but was afterwards augmented to twenty-six. They assist in the funeral services of the kings of England, are subject to the office of the canons of Windsor, and have pensions assigned them by the order of the Garter. They wear a blue or red cloak, with the arms of St George on the left shoulder.

Chapel-en-la-Frith, a market-town of England, hundred of High Peak, Derbyshire, 5 miles from Buxton, and 167 miles from London. It is surrounded by lofty hills, is well built, and has manufactures of cotton and paper, with lead and coal mines and lime works in the vicinity. It has a neat parish church, a savings-bank, national and infant schools, and (in 1851) 369 inhabitants.

Chapel-Hill, a village in the state of North Carolina, Orange county, 27 miles N.W. of Raleigh. It is the seat of the North Carolina university, founded in 1789, and has only about 400 permanent inhabitants.

CHAPELAIN, Jean (1595–1647), an eminent French poet, born at Paris, and often mentioned in the works of Balzac, Ménage, and other learned men. He wrote several works, and distinguished himself by a heroic poem called *La Pucelle, ou France Delivrée,* which has been as much decried by some as it has been extolled by others.

Chapelain translated the Spanish romance of *Guzman d'Alfarache,* and wrote *Paraphrase sur le Miserere,* 1636, 4to; several Odes; and *Mélanges de Littérature,* including *Mémoire de* [sur] *quelques gens vivans en* 1662, drawn up by order of Colbert.

CHAPERON (French), a hood or covering for the head, anciently worn both by men and women of all ranks, but afterwards appropriated to doctors and licentiates in colleges. The name eventually passed to certain little heraldic devices placed on the foreheads of horses which drew the hearse in pompous funerals. The cap worn by knights of the garter is still called a chaperon. See Cap.

CHAPLAIN, an ecclesiastic who has a chapel, or who performs service in a chapel, whether public or private.

In England there are forty-eight royal chaplains, who attend, four each month, to perform divine service for the royal family. While in waiting they have a table and attendance, but no salary. In Scotland there are six royal chaplains, with a salary of L.50 each, three of them having in addition the deanery of the chapel-royal divided among them, making up about L.600 a year to each. Their only duty at present is to say prayers at the election of representative peers for Scotland.

Chaplains *of the Pope* are the auditors or judges of causes in the sacred palace; so called because the pope anciently gave audience in his chapel, for the decision of causes sent from the several parts of Christendom. He summoned hither as assessors the most learned lawyers of his time, who hence acquired the appellation of *capellani,* chaplains. It is from the decrees formerly pronounced by these assessors that the body of Decretals is composed. Pope Sixtus IV. reduced their number to twelve. Some say the shrines of relics were covered with a kind of tent-cape, or *capella,* that is, little cape; and that hence the priests who had the care of them were called chaplains. In time these relics were deposited in a little church, either contiguous to or separate from a larger one; and the same name, *capella,* which was given to the cover, was also applied to the place where it was lodged; hence the priest who superintended it was called chaplain.

CHAPLET, a garland or wreath for the head; and frequently used to signify the circle of a crown.

Chaplet is also another name for a rosary or string of beads used by the Roman Catholics to count the number of their prayers, which consist for the most part of avemarias, paternosters, and credos. These beads are sometimes of coral, of wood, of diamonds, &c. The invention is ascribed to Peter the Hermit, who probably learnt it in the East, as the Orientals have a kind of chaplet called a *chain,* which they use in their prayers, rehearsing one of the perfections of God on each link or bead. The Turks use a similar kind of chaplet in reciting their prayers. Some, however, attribute the origin of the practice to St Dominic. The Roman Catholics have also a chaplet of our Saviour, consisting of thirty-three beads, symbolic of the years of his sojourn on earth.

CHAPMAN, George (1557–1634), the earliest English translator of Homer, was born in Kent. He studied at Trinity College, Oxford, where he was distinguished for his superior classical attainments. On his removal to London he enjoyed the friendship of Shakspeare, Spenser, Marlow, and Johnson. Besides translations from Ovid, Homer, Terence, Musæus, and Petrarch, he wrote numerous tragic and comic pieces. His translation of Homer has elicited a glowing tribute from Keats in one of his most beautiful sonnets.

CHAPPE, Claude, the inventor of the simple French telegraph, was born in Normandy in 1763. It is not now believed that he was aware of the previous devices of a similar nature by Hooke and Amontons; but he was so deeply affected by the attempts of his countrymen to deprive him of the honour of an original inventor, though the machine was adopted by the Legislative Body in 1792, that he died of deep melancholia, in 1805.

CHAPPE D'AUTEROCHE, Jean (1722–1769), a French astronomer, received his knowledge of mathematics from a Carthusian monk; and having edited a translation of the works of Dr Halley, was employed by the French government in several important observations. He observed the transit of Venus at Tobolsk in 1761, and had landed in California to make a similar observation in 1769, when he was carried off by a contagious disease.

CHAPTAL, Jean Antoine Claude, count of Chanteloup, was born at Nojaret Lozère in 1756. He early devoted himself to the study of medicine, and soon distinguished himself as a physician. His fame as a chemist had become so great, that he was called to Paris in 1793 to assist in the manufacture of gunpowder; and by his chemical knowledge and activity in the extensive factory at Grenoble, he was enabled to supply 3500 pounds per day. In the following year he returned to Montpellier, and received a

place in the administration of the department of the Hérault, with the professorship of chemistry, which had been founded there for him. He was made a member of the Institute in 1798; and having favoured the revolution of the 18th Brumaire, he was made in 1799 a councillor of state by the first consul. In the year following he was appointed minister of the interior, in which capacity he greatly encouraged the arts and sciences, and established a chemical manufactory in the vicinity of Paris. In 1804 he fell into disgrace; the reason assigned for this being that he refused to state in one of his official reports that beet-root sugar was better than that prepared from the sugar-cane. In 1805, however, the emperor bestowed on him the grand cross of the legion of honour, and a seat in the conservative senate. On Napoleon's return from Elba he was appointed director general of commerce and manufactures, and a minister of state. On the downfal of the emperor he retired to private life, and in March 1816 the king nominated him a member of the Academy of Sciences. The various vicissitudes of fortune which he underwent never diverted his attention from science, which he continued to promote and encourage till his death, which took place at Paris in August 1832.

Chaptal was director of two chemical manufactories, at Montpellier and Neuilly. He discovered the application of old wool instead of oil in the preparation of soap, and the mode of dyeing cotton with Turkish red. He invented several kinds of cement and artificial puzzolanas, by means of native calcined ochre, as also new varnishes for earthenware, without the use of lead or plumbago; and he extended the application of chemical agents in bleaching. Though Chaptal made no great or brilliant discoveries in chemistry, he was eminently distinguished as a practical chemist; and his new applications of known truths have greatly increased the obligations under which the arts lie to science.

He wrote *Elémens de Chimie*, 3 vols. 8vo, 1790; *Traité sur le Salpêtre*, 8vo, 1796; *Essai sur le Perfectionnement des Arts Chimiques en France*, 8vo, 1800; *Art de faire, de gouverner, et de perfectionner les Vins*, 1 vol. 8vo, 1801; *Traité Théorique et Pratique sur la Culture de la Vigne*, &c., 2 vols. 8vo, 1801; *Essai sur le Blanchîment*, 1801; *Chimie appliquée aux Arts*, 4 vols 8vo, 1807; *Art de la Teinture du Coton en rouge*, 8vo, 1807; *Art du Teinturier et du Dégraisseur*, 8vo, 1800; *De l'Industrie Française*, 2 vols. 8vo, 1819; *Mémoire sur le Sucre de Betteraves*, 8vo; *Chimie appliquée à l'Agriculture*, 2 vols. 8vo, 1823.

CHAPTER, in ecclesiastical polity, a society or community of clergymen belonging to a cathedral or collegiate church.

It was in the eighth century that the body of canons began to be called a chapter. The chapter of the canons of a cathedral was a standing council to the bishop, and, during the vacancy of the see, had the jurisdiction of the diocese. In the earlier ages the bishop was head of the chapter; afterwards abbots and other dignitaries, as deans, provosts, and treasurers, were preferred to this distinction. The deans and chapters had the privilege of choosing the bishops in England; but Henry VIII. had this power vested in the crown; and as the same prince expelled the monks from the cathedrals, and placed secular canons in their room, those whom he thus regulated were called deans and chapters of the new foundation, such as Canterbury, Winchester, Ely, Carlisle, &c.

CHAPU, an important maritime town of China, province of Chehkiang, 50 miles N.W. of Chinhai. It is the port of Hangchau, with which it has good canal communication, and is the only Chinese port trading with Japan. It was attacked and much injured by the British force in 1842, but was abandoned immediately after the engagement.

CHARACTER, in a general sense, signifies a mark or figure, drawn on paper, metal, stone, or other matter, with a pen, graver, chisel, or other instrument, to signify or denote any thing. The word is Greek, χαρακτηρ, formed from the verb χαρασσω, *insculpere*, to engrave or impress.

The various kinds of characters may be reduced to three heads, viz. *Literal Characters*, *Numeral Characters*, and *Abbreviations*.

I. *Literal* CHARACTER is a letter of the alphabet, serving to indicate some articulate sound.

1. These may be divided, with regard to their nature and use, into *Nominal Characters*, or those we properly call *letters*, which serve to express the names of things; *Real Characters*, those that instead of names express things and ideas; *Emblematical* or *Symbolical Characters*, which have this in common with real ones, that they express the things themselves, but, further, possess the peculiarity of in some measure personating them, and exhibiting their form, such as the hieroglyphics of the ancient Egyptians.

2. *Literal* CHARACTERS may be again divided, with regard to their invention and use, into *particular* and *general* or *universal*.

Particular CHARACTERS are those peculiar to this or that nation, such as the Roman, Italic, Greek, Hebrew, Arabic, Gothic, and Chinese *characters*.

Universal CHARACTERS are also *real characters*, and constitute what some authors call a *Philosophical Language*.

That diversity of *characters* used by several nations to express the same idea is found the chief obstacle to the advancement of learning. To remove this, several ingenious thinkers have taken occasion to propose plans of *characters* which should be universal, and which each people should read in their own language. The object is to render *character* real, not nominal; to express things and notions, not letters or sounds; yet to be mute like letters, and arbitrary, not emblematical, like hieroglyphics. Thus, every nation would retain its own language, yet every one would understand that of every other without learning it, only by seeing a real or universal *character*, which should signify the same thing to all people, by what sounds soever it might be expressed in their particular idiom. For instance, by seeing the *character* destined to signify *to drink*, an Englishman would read *to drink*; a Frenchman, *boire*; a Latin, *bibere*; a Greek, πινειν; a Jew, שתה; a German, *trincken*, and so of the rest; in the same manner as seeing a horse, each people would express it after their own manner, but all would mean the same animal.

The first and most considerable attempts at a *real character*, or philosophical language, in Europe, are those of Bishop Wilkins and Dalgarno; but they proved wholly ineffectual. M. Leibnitz, indeed, thought that those ingenious men did not hit the right method. It was probable, indeed, that by their contrivance people who do not understand one another might easily have a commerce together; but they have not hit on true *real characters*. According to him, the *characters* should resemble those used in algebra, which, in effect, are very simple, yet very expressive, without any thing superfluous or equivocal, and contain all the varieties required. M. Lodwic, in the *Philosophical Transactions*, gives us a plan of *an universal alphabet* or *character* of another description. This was to contain an enumeration of all such single sounds or letters as are used in any language, by means of which people should be enabled to pronounce truly and readily any language; to describe the pronunciation of any language that might be pronounced in their hearing, so that others accustomed to this language, though they had never heard it pronounced, should at first be able truly to pronounce it; and, lastly, this *character* was to serve as a standard to perpetuate the sounds of any language.

A new universal character was proposed by Mr Northmore of London, by which different nations might communicate their sentiments to each other. His original plan

was to make the same numerical figure represent the same word in all languages. But he found afterwards that it might be improved by using a figure, not for every word, but for every *useful* word. And even these, he thinks, might be abbreviated by adopting certain uniform fixed signs, the number of which would not exceed twenty for the various parts of speech. Words of negation he proposed to be expressed by a prefixed sign. A few instances will explain the author's meaning.

Suppose the number 5 to represent the word *see*,

6 .... *a man*,
7 .... *happy*,
8 .... *never*,
9 .... *I*.

" I would then," says he, " express the tenses, genders, cases, &c. *in all languages*, in some such *uniform* manner as the following:

(1)	5	=	*present tense*	see.
(2)	.5	=	*perfect tense*	saw.
(3)	:5	=	*perfect participle*	seen.
(4)	5:	=	*present participle*	seeing.
(5)	5.	=	*future*	will see.
(6)	$\underline{5}$	=	*substantive*	sight.
(7)	$\underline{\underline{5}}$	=	*personal substantive*	spectator.
(8)	$\underset{..}{6}$	=	*nominative case*	a man.
(9)	$.\underset{..}{6}$	=	*genitive*	of a man.
(10)	6	=	*dative*	to a man.
(11)	$\overset{\frown}{6}$	=	*feminine*	a woman.
(12)	+6	=	*plural*	men.
(13)	7	=	*positive*	happy.
(14)	$\hat{7}$	=	*comparative*	happier.
(15)	$\hat{\hat{7}}$	=	*superlative*	happiest.
	$\underline{7}$	=	as above, No. 6	happiness.
(16)	—7	=	*negation*	unhappy.

" From the above specimen, I should find no difficulty in comprehending the following sentence, though it were written in the language of the Hottentots:

$9, 8, .5, -\hat{7}, \overset{\frown}{6}.$ *I never saw a more unhappy woman.*

" Those languages which do not use the pronoun prefixed to the verb, as the Greek and Roman, may apply it in a small character, simply to denominate the person; thus, instead of 9, 8, .5, *I never saw*, they may write 8, ${}_9.5$, which will signify that the verb is in the first person, and will still have the same meaning."

Our author thinks, that according to this scheme of an universal character, about twenty signs, and less than 10,000 *chosen* words, synonyms being set aside, would answer all the ends proposed; and that foreigners, by referring to their numerical dictionary, would easily comprehend each other. He proceeds next to show how appropriate sounds may be given to his signs, and an universal *living language* formed from the universal *characters*.

With this view he proposes to distinguish the ten numerals by ten monosyllabic names of easy pronunciation, or such as may without difficulty run into one another. To illustrate his scheme, however, he calls them, for the present, by their common English names, but suggests that each number made use of should be pronounced by uttering separately its component parts, after the manner of accountants. Thus, let the number 6943 represent the word *horse*, he would not, in the universal language, call a horse *six thousand nine hundred and forty-three*, but *six, nine, four, three;* and so on for all the words of a sentence, making the proper stop at the end of each. In the same manner, a distinct appellation must be appropriated to each of the prefixed signs, to be pronounced immediately after the numeral of which it is an appendage. Therefore, if *plu* be the appellation or the sign of the plural number, *six, nine, four, three, plu*, will be *horses*.

" Thus," says our author, " I hope it is evident that about thirty or forty distinct syllables are sufficient for the above purpose; but I am much mistaken if *eleven* only will not answer the same end. This is to be done by substituting the first twenty or thirty numerals for the signs, and saying, as in algebra, that a term is in the power of such a number, which may be expressed by the simple word *under*. For example, let 6943 represent the word *horse*, and suppose 4 to be the sign of the plural number, I would write the word thus, $\frac{4}{6943}$, and pronounce it six, nine, four, three, in the power of or *under* four. By these means eleven distinct appellations would be sufficient, and time and use would much abbreviate the pronunciation."

3. Literal characters may again be divided, with reference to the nations among whom they have been invented, into Greek characters, Roman characters, Hebrew characters, and the like. The Latin character now used throughout all Europe was formed from the Greek, as the Greek was formed from the Phœnician; and the Phœnician, as well as the Chaldee, Syriac, and Arabic characters, were formed from the ancient Hebrew, which subsisted till the Babylonish captivity; for after that event the character of the Assyrians, which is the square Hebrew now in use, prevailed, the ancient being only found on some Hebrew medals, commonly called Samaritan medals. It was in 1091 that the Gothic characters, invented by Ulphilas, were abolished, and the Latin ones established in their room.

Medallists observe that the Greek character, consisting only of majuscule letters, has preserved its uniformity on all medals as low as the time of Gallienus, after which it appears somewhat weaker and rounder. From the time of Constantine to that of Michael we find only Latin characters; after the time of Michael the Greek characters recommence; but from that period they began to alter with the language, which was a mixture of Greek and Latin. The Latin medals preserved both their characters and language as late as the translation of the seat of the empire to Constantinople. Towards the time of Decius the character began to lose its roundness and beauty; but some time afterwards it retrieved, and subsisted tolerably till the time of Justin, when it degenerated gradually into the Gothic. The rounder, then, and better-formed a character is upon a medal, the fairer pretence it has to antiquity.

II. *Numeral* CHARACTERS, or characters used to express numbers, are either letters or figures.

The Arabic character, called also the common one, because it is used almost throughout Europe in all sorts of calculations, consists of the ten digits, 1, 2, 3, 4, 5, 6, 7, 8, 9, 0.

The Roman numeral character consists of seven majuscule letters of the Roman alphabet, viz. I, V, X, L, C, D, M. The I denotes one, V five, X ten, L fifty, C a hundred, D five hundred, and M a thousand. The I repeated twice makes two, II; thrice, three, III. Four is expressed thus, IV, as I before V or X takes an unit from the number expressed by these letters. To express six an I is added to a V, thus, VI; for seven, two, VII; and for eight, three, VIII. Nine is expressed by an I before X, thus, IX. The same remark may be made of the X before L or C, except that the diminution is by tens; thus, XL

denotes forty, XC ninety, and LX sixty. The C before D or M diminishes each by a hundred. The number five hundred is sometimes expressed by an I before a C inverted, thus, IↃ; and instead of M, which signifies a thousand, an I is sometimes used between two C's, the one direct and the other inverted, thus, CIↃ. The addition of C and Ↄ before or after raises CIↃ by tens; thus, CCIↃↃ expresses ten thousand, CCCIↃↃↃ a hundred thousand. The Romans also expressed any number of thousands by a line drawn over any numeral less than a thousand; thus, $\overline{V}$ denotes five thousand, $\overline{LX}$ sixty thousand; so likewise $\overline{M}$ is one million, $\overline{MM}$ is two millions, and so on.

The Greeks had three ways of expressing numbers: 1. Every letter, according to its place in the alphabet, denoted a number, from α, one, to ω, twenty-four. 2. The alphabet was divided into eight units, α one, β two, γ three, &c.; into eight tens, ι ten, κ twenty, λ thirty, &c.; and eight hundreds, ϱ one hundred, σ two hundred, τ three hundred, &c. 3. Ι stood for one, Π five, Δ ten, Η a hundred, Χ a thousand, Μ ten thousand; and when the latter Π inclosed any of these, except Ι, it showed the inclosed letter to be five times its value; as, |Δ| fifty, |Η| five hundred, |Χ| five thousand, |Μ| fifty thousand.

III. Characters of Abbreviations, &c. in several of the arts, are symbols contrived for the more concise and immediate conveyance of the knowledge of things.

Of the Aspects.

☌ or S Conjunction	△ Trine
SS Semisextile	Bq Biquintile
* Sextile	Vc Quincunx
Q Quintile	☍ Opposition
□ Quartile	☊ Dragon's head
Td Tredecile	☋ Dragon's tail

Of Time.

A. M. *ante meridiem*, before the sun comes upon the meridian.
O. or N. noon.
P. M. *post meridiem*, when the sun is past the meridian.

Characters in Commerce.

D° *ditto*, the same	S or *s*, shillings
N° *numero*, or number	*d*, pence or deniers
F° *folio*, or page	℔ pound weight
C or ⊕ hundredweight, or 112 pounds	R° *recto* } *folio* / V° *vero* } *folio*
qts quarters	Rx rixdollar
L. or *l.* pounds sterling	Dt ducat
pr *per* or by, pr *ann.* by the year, pr *cent.*	P. S. postscript, &c.

Characters in Geometry and Trigonometry.

‖ the character of parallelism	≚ equiangular or similar
△ triangle	≟ equilateral
□ square	∠ an angle
▭ rectangle	∟ right angle
⊙ circle	⊥ perpendicular

° denotes a degree; thus, 45° implies 45 degrees.
′ denotes a minute; thus, 50′ is 50 minutes. ″, ‴, ⁗, denote seconds, thirds, and fourths; and the same characters are used when the progressions are by tens, as it is here by sixties.

Characters in Grammar, Rhetoric, Poetry, &c.

( ) parenthesis	D. D. doctor in divinity
[ ] crotchet	V. D. M. minister of the word of God
- hyphen	LL. D. doctor of laws
' apostrophe	J. U. D. doctor of civil and canon law
` emphasis or accent	M. D. doctor of medicine
˘ breve	A. M. master of arts
¨ dialysis	A. B. bachelor of arts
^ caret and circumflex	F. R. S. fellow of the royal society
† ‡ and * references	(See Abbreviations.)
§ section or division	
¶ paragraph	
" quotation	

Characters among the ancient Lawyers, and in ancient Inscriptions.

§ paragraph	C. code
ff digests	C C. consules
Scto. senatus consulto	T. titulus
E. extra	P. P. D. D. propria pecunia dedicavit
S. P. Q. R. senatus populusque Romanus	D. D. M. dono dedit monumentum
P. P. pater patriæ	

Characters in Medicine and Pharmacy.

℞ recipe	coch. cochleare, a spoonful
ā, āā, or ana, of each alike	M. manipulus, a handful
℔ a pound, or pint	P. a pugil
℥ an ounce	P. Æ. equal weights
ʒ a drachm	S. A. according to art
℈ a scruple	q. s. a sufficient quantity
gr. grains	q. pl. as much as you please
ß or *f s* half of any thing	P. P. pulvis patrum, the Jesuits' bark
cong. congius, a gallon	

Characters upon Tomb-stones.

S. V. Siste viator, *i. e.* stop traveller
M. S. Memoriæ sacrum, *i. e.* sacred to the memory
D. M. Diis manibus
J. H. S. Jesus hominum salvator
X. P. a character found in the catacombs, about the meaning of which authors are not agreed.

Characters used in Music, and of Musical Notes with their proportions, are as follows:

character of a large......8	crotchet............... $\frac{1}{4}$
a long.....................4	quaver.................. $\frac{1}{8}$
a breve....................2	semiquaver........... $\frac{1}{16}$
a semibreve...............1	demisemiquaver...... $\frac{1}{32}$
a minim.................... $\frac{1}{2}$	

※ or ♯ character of a sharp note; this character at the beginning of a line or space denotes that all the notes in that line are to be taken a semitone higher than in the natural series; and the same affects all the octaves above and below, though not marked; but when prefixed to any particular note, it shows that note alone to be taken a semitone higher than it would be without such a character.

♭ or *b*, character of a flat note. This is the contrary to the other above; that is, a semitone lower.

♮ character of a natural note. When in a line or series of artificial notes marked at the beginning ♭ or ♯, the natural note happens to be required, it is denoted by this character.

𝄞 character of the treble clef
character of the mean clef
𝄢 bass clef

$\frac{2}{4}$ or $\frac{2}{8}$, characters of common duple ime, signifying the

measure of two crotchets to be equal to two notes, of which four make a semibreve.

C ₵ Ф characters that distinguish the movements of common time, the first implying slow, the second quick, and the third very quick.

$\frac{1}{2}$, $\frac{1}{3}$, $\frac{3}{4}$, $\frac{3}{8}$, $\frac{1}{16}$, characters of simple triple time, the measure of which is equal to three semibreves, or to three minims.

$\frac{4}{6}$, $\frac{6}{8}$, or $\frac{6}{16}$, characters of a mixed triple time, where the measure is equal to six crotchets or six quavers.

$\frac{9}{4}$, or $\frac{9}{8}$, or $\frac{9}{16}$, or $\frac{9}{1}$, or $\frac{9}{2}$, characters of compound triple time.

$\frac{4}{12}$, $\frac{8}{12}$, $\frac{12}{16}$, or $\frac{1}{12}$, or $\frac{2}{12}$, characters of that species of triple time called the measure of twelve times.

CHARACTER, in human life, that which is peculiar in the manners of any person, and distinguishes him from all others.

CHARACTER, in *Poetry*, particularly the epopee and drama, is the effect or result of the manners or peculiarities by which each person is distinguished from others.

The poetical character is not properly any particular virtue or quality, but a composition of several which are mixed together in different degrees, according to the necessity of the fable and the unity of the action; there must be one, however, to reign over all the rest, and this must be found, in some degree, in every part. The first quality in Achilles is wrath, in Ulysses dissimulation, and in Æneas mildness; but as these characters cannot stand alone, they must be accompanied with others to embellish them, as far as they are capable, either by hiding their defects, as in the anger of Achilles, which is palliated by extraordinary valour; or by making them centre in some solid virtue, as in Ulysses, whose dissimulation constitutes part of his prudence; and in Æneas, whose mildness is employed in submission to the will of the gods. In the making up of this union, it is to be observed, that the poets have joined together such qualities as are by nature the most compatible; valour with anger, piety with mildness, and prudence with dissimulation. The fable required prudence in Ulysses and piety in Æneas; in this, therefore, the poets were not left to their own choice. But Homer might have made Achilles a coward without abating any thing from the justness of his fable; and it was only the necessity of adorning his character that obliged him to make him valiant. The character, then, of a hero in the epic poem is compounded of three sorts of qualities; the first essential to the fable, the second embellishments of the first, while valour, which sustains the other two, constitutes the third.

Unity of character is as necessary as the unity of the fable. For this purpose a person should be the same from the beginning to the end; not that he is always to betray identical sentiments, or one passion; but that he should never speak nor act inconsistently with his fundamental character. For instance, the weak may sometimes burst into warmth, and the breast of the passionate may be calm; a change which often introduces into the drama a very affecting variety: but if the natural disposition of the former were to be represented as boisterous, and that of the latter as mild and soft, they would both act out of character, and contradict their personality.

True characters are such as we actually see in men, or as may exist without any contradiction to nature. No man questions but there have been men as generous and as good as Æneas, as passionate and as violent as Achilles, as prudent and as wise as Ulysses, as impious and atheistical as Mezentius, and as amorous and passionate as Dido. All these characters, therefore, are true, and nothing but just imitations of nature. On the contrary, a character is false when the author so feigns it that one can see nothing like it in the order of nature in which he designs it shall stand. Such characters should be wholly excluded from a poem, because, transgressing the bounds of probability and reason, they meet with no belief from the reader. They are fictions of the poet's brain, not imitations of nature; and yet all poetry consists of an imitation of nature.

CHARADE, the name of a fanciful species of composition or literary amusement. It owes its name to the idler who invented it. Its subject is usually a word of two syllables, each forming a distinct word; and these two syllables are to be concealed in an enigmatical description, first separately, and then together. The exercise of charades, if not greatly instructive, is at least innocent and amusing. Most of those which have appeared from time to time are not only destitute of all pleasantry, but are formed in general of words utterly unfit for the purpose. In trifles of this nature inaccuracy is without excuse. The following examples, therefore, are at least free from this blemish.

1. My *first*, however here abused,
Designs the sex alone;
In Cambria, such is custom's pow'r,
'Tis Jenkin, John, or Joan.
My *second* oft is loudly call'd,
When men prepare to fist it;
Its name delights the female ear;
Its force, may none resist it:
It binds the weak, it binds the strong,
The wealthy and the poor;
Still 'tis to joy a passport deem'd,
For sullied fame a cure.
It may insure an age of bliss,
Yet mis'ries oft attend it;
To fingers, ears, and noses too,
Its various lords commend it.
My *whole* may chance to make one drink,
Though vended in a fish shop;
'Tis now the monarch of the seas,
And has been an archbishop. *Her-ring.*

2. My *first*, when a Frenchman is learning English, serves him to swear by. My *second* is either hay or corn. My *whole* is the delight of the present age, and will be the admiration of posterity. *Gar-rick.*

3. My *first* is ploughed for various reasons, and grain is frequently buried in it to little purpose. My *second* is neither riches nor honours, yet the former would generally be given for it, and the latter is often tasteless without it. My *whole* applies equally to spring, summer, autumn, and winter; and both fish and flesh, praise and censure, mirth and melancholy, are the better for being in it. *Sea-son.*

4. My *first*, with the most rooted antipathy to a Frenchman, prides himself, whenever they meet, upon sticking close to his jacket. My *second* has many virtues, nor is it its least that it gives name to my first. My *whole* may I never catch! *Tar-tar.*

5. My *first* is one of England's prime boasts; it rejoices the ear of a horse, and anguishes the toe of a man. My *second*, when brick, is good; when stone, better; when *wooden*, best of all. My *whole* is famous alike for rottenness and tin. *Corn-wall.*

6. My *first* is called bad or good,
May pleasure or offend ye;
My *second*, in a thirsty mood,
May very much befriend ye.
My *whole*, though styled a "cruel word,"
May yet appear a kind one;
It often may with joy be heard,
With tears may often blind one. *Fare-well.*

7. My *first* is equally friendly to the thief and the lover, the toper and the student. My *second* is light's opposite, yet they are frequently seen hand in hand; and their

union, if judicious, gives much pleasure. My *whole* is tempting to the touch, grateful to the sight, but fatal to the taste. *Night-shade.*

CHARCOAL. When vegetable substances are subjected to a strong heat in the apparatus for distillation, the fixed residue is called charcoal. Charcoal is made in various ways. For general use it is obtained by building up pieces of wood in a pyramidal form, then covering the pile with earth or clay, leaving a few air-holes, which are closed when the mass is lighted, in order that combustion may proceed in a slow and imperfect manner. Charcoal of a very superior kind is made in the forest of Benon, near Rochelle, where great attention is paid to its manufacture. Black oak from ten to fifteen years old is cut into billets of about four feet in length, which are built up as above described, and, before being inclosed in the clay or earth, covered over to the depth of four inches with dry grass or fern. When the mass is charred, great care is taken to extinguish ignition, because if exposed too soon to the atmosphere, combustion goes on, and this is not put a stop to without difficulty. Accordingly, to obviate this, a barrel of water is thrown over the pile, and earth to the thickness of five or six inches is spread on it, after which it is left for twenty-four hours to cool. Charcoal is also made on a great scale in the following manner. A series of cast-iron cylinders, about four feet in diameter and six feet in length, are built horizontally into brickwork, so that the flame of one furnace may play round about two cylinders. The ends are made to project from the brickwork, and both are closed with discs of iron. From the centre of one of these an iron tube proceeds, and enters at a right angle the main tube of refrigeration. The vapour which is condensed in this vessel is a strong vinegar called pyroligneous acid. The tubes of course are filled with wood cut up into billets. Fire is applied during the day; all night they are allowed to cool, and next morning the charge is drawn. Care is taken to prevent the access of air, both while the wood is charring, and after it has begun to cool. When charcoal is wanted for the manufacture of gunpowder, it is necessary that the whole of the vinegar and tar should be allowed to escape, and that the reabsorption of the vapours should be prevented, by cutting off the communication between the interior of the cylinder and the apparatus for condensing the pyroligneous acid after the fire has been withdrawn from the furnace. Unless this precaution be taken, the gunpowder manufactured with the charcoal will be of inferior quality. Mr Mushet has made a number of valuable experiments respecting charcoal. The following is his table of results, reduced to 100 parts, from experiments on one pound avoirdupois of various kinds of wood.

	Volatile Matter.	Charcoal.	Ashes.
Oak	76·895	22·682	0·423
Ash	81·260	17·972	0·768
Birch	80·717	17·491	1·792
Norway Pine	80·441	19·204	0·355
Mahogany	73·528	25·492	0·980
Sycamore	79·20	19·734	1·066
Holly	78·92	19·918	1·162
Scotch Pine	83·095	16·456	0·449
Beech	79·104	19·941	0·955
Elm	79·655	19·574	0·761
Walnut	78·521	20·663	0·816
American Maple	79·331	19·901	0·768
American Black Beech	77·512	21·445	1·033
Laburnum	74·234	24·586	1·180
Lignum Vitæ	72·643	26·857	0·500
Sallow	80·371	18·497	1·132
Chestnut	76·304	23·280	0·416

By a long continued moderate heat Rumford obtained a much larger quantity of charcoal from wood; but Berzelius states, that wood in general yields from 22 to 27 per cent. of charcoal, according to the kind of wood, and the process employed. The best wood charcoal for gunpowder is obtained from spongy trees, such as the alder, the white willow, and the poplar. We are informed by M. Proust that good pit-coals afford 70, 75, or 80 per cent. of charcoal, which leaves of ashes after combustion only two or three parts in the hundred. This species is much used in Great Britain under the name of coke. Turf or peat has been lately charred in France by a peculiar process. It is considered as superior to that obtained from wood. It kindles more slowly, but emits more flame, and burns longer than the other. Gold fused by it retains its malleability; and this property is increased in iron heated red hot by it in a forge.

Charcoal is black, sonorous, and brittle, and generally retains the figure of the vegetable from which it was obtained. The charcoal produced from oily or bituminous substances is of a light pulverulent form, and rises in the form of soot. This charcoal of oils is well known in the arts under the name of lamp-black. What is called *animal charcoal* is obtained from the carbonaceous portion of bones. For an account of the chemical and other properties of charcoal, see CHEMISTRY, where it will be found treated of under the scientific appellation CARBON. (Ure's *Dictionary of Chemistry;* Tilloch's *Magazine*, vols. iii. and viii., On the Economical Application of Charcoal to Sanitary purposes, by John Stenhouse, LL.D., and J. Forbes Watson, M.A. London, 1855.)

CHARD, a municipal borough and market-town of England, Somersetshire, hundred of East Kingsbury, 18 miles S. of Bridgewater, and 139 miles from London. It was made a parliamentary borough, returning 2 members to parliament, by Edward I., but deprived of that privilege in the reign of Edward III. The town stands upon an eminence on the S. border of the county, is well built, and has manufactures of lace and woollen goods. Pop. (1851) 2291.

CHARDIN, SIR JOHN, a celebrated traveller, was born at Paris in 1643. His father, who was a jeweller, educated him for his own profession; and partly on business and partly to gratify his own inclination he set out on his travels to Persia and India. He visited these countries twice; and settling at last in London as jeweller to the court, he died there in 1713. He wrote an account of his travels in these regions which furnished to Montesquieu, Rousseau, Gibbon, and Helvetius, an accurate knowledge of the political system of Persia. His monument in Westminster Abbey bears the following inscription—*Nomen sibi fecit eundo.*

CHARENTE, an inland department in the S.W. of France, comprehending the ancient division of Angoumois, with inconsiderable portions of Saintonge, Poitou, and Limousin. It is bounded N. by the departments of Deux-Sèvres and Haute-Vienne; E. by those of Vienne and Dordogne; S. and W. by those of Dordogne and Charente-Inférieure. Area 2670 square miles. The great part of it consists of the valley of the river Charente, which rises in Haute-Vienne, and after a circuitous course passes into Charente-Inférieure, where it falls into the sea opposite Isle-Madame. Principal tributaries—the Tardoire, Touvres, Né Seugne, Antoine, and Boutonne. The Charente, though rapid, has been rendered navigable artificially; and steamers ply between Angoulême and Saintes, although the tide ascends no higher than the latter. The surface is comparatively level, and subject to frequent inundations. In the arrondissement of Confolens are upwards of 60 small lakes. The hills are generally uniform in height, and abound in marine deposits; while some of them are covered with chestnut forests. Climate temperate; prevailing winds W. and S.W. Principal productions, wine, corn, hemp, flax, and potatoes. The wine is largely distilled into brandy, for which Cognac is famous. The value of truffles annually brought to market is estimated at 300,000 francs. Pigs, sheep, and poultry are extensively reared for the Paris market. Its mineral productions consist chiefly of iron, lead, antimony, and

gypsum, of which iron and gypsum only are worked to any extent. Among its manufactures paper occupies the foremost place; but canvas, linen cloth, hats, cordage, hoops, and pottery are also made. Charente is divided into five arrondissements, deriving their names from the five principal towns. Their divisions and populations are as follows, viz.:—

Arrondissements.	Cantons.	Communes.	Pop. (1851.)
Angoulême	9	144	137,696
Cognac	4	70	57,959
Ruffec	4	82	59,260
Barbézieux	6	88	56,557
Confolens	6	70	71,440
Total	29	454	382,912

CHARENTE-INFERIEURE, or *Lower Charente*, a maritime department of France, comprehending the old provinces of Saintonge and Aunis, and including the islands of Ré, Oleron, Aix, and Madame. It is bounded N. by Vendée and Deux-Sèvres; E. by Charente; S. by Gironde, and W. by the Bay of Biscay. Area 2757 square miles. The surface is exceedingly flat throughout the whole department, and along the coast-line it is so far depressed as to require in many places the erection of sea-dikes and extensive artificial draining. Its facilities for internal communication are greatly increased by the number of navigable streams, and the formation of two canals, one from La-Rochelle to the Sèvre Niortaise, the other from Brouage to Rochefort. The productions very nearly coincide with those of Charente, with this difference—that its wines and brandy are greatly inferior, but its fruits and vegetables greatly superior to those of the upper province. It has also more extensive pasturage, and considerable revenue accruing from the pilchard and oyster fisheries on the coast, but its mineral wealth and manufactures are neither so various nor so productive. The former is confined to the salt supplied by marshes along the coast; the latter includes coarse woollen stuffs, leather, soap, earthenware, staves, and timber. It has several sheltered bays on the coast, and several good harbours, at which a brisk coasting trade is carried on. It has considerable trade in colonial produce; and shipbuilding is prosecuted to some extent. The climate is salubrious, except along the coast, where fevers and ague prevail. It is divided into six arrondissements, cognominal with the principal towns, which are subdivided and peopled as follows:—

Arrondissements.	Cantons.	Communes.	Pop. (1851.)
La-Rochelle	7	55	82,293
Rochefort	4	47	61,760
Marennes	6	34	51,689
Saintes..............	8	99	107,513
Jouzac	7	120	83,706
St Jean d'Angely	7	126	83,031
Total	39	481	469,992

CHARENTON-LE-PONT, a town of France, department of Seine, pleasantly situated on the right bank of the Marne, near its confluence with the Seine, 5 miles E.S.E. of Paris. Pop. 3000. The Marne is here crossed by a bridge of 10 arches, which has frequently been the scene of sanguinary conflicts, and has always been regarded as of great importance in the defence of the capital. This bridge unites the town with the village of Charenton St Maurice, where there is a large national lunatic asylum.

CHARES, of Lindus in Rhodes, a celebrated statuary, the sculptor of the famous statue of the Sun generally known as the "Colossus of Rhodes," which was regarded as one of the seven wonders of the world. See COLOSSUS. He was the favourite pupil of Lysippus, and flourished about B.C. 290.

CHARGE, in *Heraldry*, the figures represented on the escutcheon, by which the bearers are distinguished from one another.

CHARIOT, a half coach or carriage with four wheels and one seat, used for convenience and pleasure.

The chariots of the ancients had two wheels, and were supported by a pole (or sometimes by two, or even three, as among the Lydians). They were used in war and in the public games, and were called by the several names of *bigæ*, *trigæ*, or *quadrigæ*, according to the number of horses used to draw them. A chariot carried two men, the warrior and the charioteer; and we read of several men of note and valour employed in driving the chariot. When the warriors came to encounter in close fight, they alighted and fought on foot; and when weary, they retired to their chariots, and thence annoyed the enemy with darts and missile weapons. These chariots were so strongly built that they lasted for several generations.

We also find frequent mention of the *currus falcati*, or chariots armed with hooks or scythes, with which whole ranks of soldiers were sometimes cut down. These were used by the Persians, Syrians, Egyptians, and other eastern nations, and also among the ancient Britons. By the Greek and Roman historians these chariots are described by the various names of *benna*, *petoritum*, *currus* or *carrus*, *covinus*, *essĕdum*, and *rheda*. The *benna* seems to have been a chariot designed rather for travelling than for war. It contained two persons, who were thence called *combennones*. The *petoritum* seems to have been a larger kind of chariot than the *benna*, and is thought to have derived its name from the British word *pedwar*, signifying *four*, as this kind of carriage had four wheels. The *carrus* or *currus* was the common cart or waggon. This kind of chariot was used by the ancient Britons, in time of peace, for the purposes of agriculture and merchandise; and, in time of war, for carrying their baggage, and wives and children, who commonly followed the armies of all the Celtic nations. The *covinus* was a war-chariot, and a very terrible instrument of destruction, being armed with sharp scythes and hooks for cutting and tearing all who happened to come within its reach. This kind of chariot was made very light, being designed to drive with great force and rapidity, and to do execution chiefly with its hooks and scythes. The *essedum* and *rheda* were also war-chariots, probably of a larger size and stronger make than the *covinus*, being designed for containing a charioteer to conduct it, and one or two warriors to fight. The greater number of the British war-chariots seem to have been of this kind. These chariots were found in great numbers among the Britons; insomuch that, according to Cæsar, Cassivelaunus, after dismissing all his other forces, retained no fewer than four thousand war-chariots about his person. The same author relates, that by continual practice they had arrived at such perfection in the management of their chariots, that in the most steep and difficult places they could stop their horses when at full speed, turn them which way they pleased, run along the pole, rest on the harness, and throw themselves back into their chariots with incredible dexterity.

CHARIOTS were sometimes consecrated to the sun; and it is related in Scripture that Josiah burnt those which had been offered to the sun by the kings, his predecessors. This superstitious custom was an imitation of the heathens, and principally of the Persians, who had horses and chariots consecrated in honour of the sun. Herodotus, Xenophon, and Quintus Curtius, speak of white chariots crowned, which, among the Persians, were consecrated to the sun, and drawn by white horses.

Triumphal CHARIOT, was one of the principal ornaments of the Roman celebration of a victory.

The Roman triumphal chariot was generally made of ivory, and round like a tower, or rather of a cylindrical figure. It was sometimes gilded at the top, and ornamented with crowns; and in short the utmost skill was employed to render it as splendid as possible. It was commonly drawn

by four white horses; but also frequently by lions, elephants, tigers, bears, leopards, &c.

CHARISIUS, a surname of Zeus (Jupiter), derived from χάρις, *gratia*, grace or favour. It was customary among the Greeks at their meals to make a libation to Jupiter Charisius.

CHARISTIA, an annual festival of the Romans, celebrated on the 19th of February, in which the relations and members of the same family met, in order that any difference among them might the more easily be accommodated by the good humour and mirth of the entertainment. (Ovid, *Fast.* ii.)

CHARISTICARIES, in ecclesiastical history, among the Greeks, were a kind of donatories or commendatories, who enjoyed uncontrolled power over the revenues of hospitals and monasteries. The origin of this abuse is referred to the iconoclasts in the eighth century, and particularly to the emperor Constantine Copronymus, the avowed enemy of the monks, whose monasteries he gave away to strangers. In after-times the emperors and patriarchs gave many to persons of rank, not to enable the donatories to reap any temporal advantage from the grants, but to repair, beautify, and patronize them. But avarice prevailed over these good intentions, so that at length they were all given away, rich and poor, monasteries and nunneries, and that even to laymen and to married men.

CHARITE, La, a town of France, department of Nievre, on the right bank of the Loire, here crossed by a handsome bridge. It is an ancient town, formerly of greater importance, and is still partly surrounded by ramparts flanked by towers of the fourteenth century. It has an active trade, and considerable manufactures of hardware, jewellery, glass, earthenware, &c. Pop. 4500.

CHARITES, the three graces, Euphrosyne, Aglaia, and Thalia; called *Gratiæ* by the Romans. See Graces.

CHARITON, of Aphrodisias in Caria, a Greek writer, who probably lived about the fifth century of the Christian era. He was the author of the *Loves of Chæreas and Callirrhöe*, a romance of small invention, which has been translated into German and French. The best edition is that by D'Orville, reprinted by Beck, Lips. 1783.

CHARITY, one of the three grand Scriptural virtues, consisting in the love of God and of our neighbour, or the habit and disposition of loving God with all our heart, and our neighbour as ourselves.

Charity also denotes the effect of moral virtue, which consists in supplying the necessities of others, whether with money, counsel, assistance, or the like.

Brothers of Charity, a sort of religious hospitallers founded about the year 1297, since denominated *Billetins*. They took the third order of St Francis, and the scapulary, making the three usual vows, but without begging.

Brothers of Charity also denotes an order of hospitallers still subsisting in Catholic countries, whose business is to attend the sick poor, and minister to them both spiritual and temporal succour. They are all laymen, except a few priests for administering the sacraments to the sick in their hospitals. The brothers of charity usually cultivate botany, pharmacy, surgery, and chemistry, which they practise with success. They were first founded at Granada by St John de Dieu; and a second establishment was made at Madrid in 1553. The order was confirmed by Gregory XIII. in 1572. Gregory XIV. forbade them to take holy orders; but by leave of Paul V. in 1609, a few of the brothers might be admitted to orders. In 1619 they were exempted from the jurisdiction of the bishop. Those of Spain are separated from the rest; and they, as well as the brothers of France, Germany, Poland, and Italy, have their distinct generals, who reside at Rome. They were first introduced into France by Mary of Medicis in 1601, and have a fine hospital in the fauxbourg St Germain

Sisters of Charity (*Sœurs de la Charité*), an order of female hospitallers, revived in France since the commencement of the present century, and consisting chiefly of professed nuns who devote themselves to the duties of attending the poor and sick in the hospitals, ministering to their wants, dressing their sores, and affording them religious consolation. This order includes females belonging to some of the first families in France.

CHARKOV. See Kharkov.

CHARLATAN, one who prates much in commendation of himself, and makes unwarrantable pretensions to skill; originally an empiric or quack, a retailer of medicines on a public stage, who attracted notice by his buffooneries, feats of activity, and the like. The word, according to Calepine, comes from the Italian *ceretano*, from Cæretum, a town near Spoleto, where these impostors are said to have first appeared. Ménage, however, derives it from *ciarlatano*, and that from *circulatorius* or *circulator*, a mountebank.

CHARLEMAGNE, or Charles I. king of France, and emperor of the West by conquest, was born at the castle of Salzburg in Upper Bavaria in 742. The events in the life of this great monarch belong properly to the history of France. Equally illustrious in the cabinet and in the field, a wise legislator and a great warrior, the patron of men of letters and the restorer of learning, Charlemagne has united in his favour the suffrages of statesmen and soldiers, of ecclesiastics, lawyers, and men of letters, who have all vied with one another in bestowing the homage of their praise on the celebrated founder of the western empire. Politicians indeed have blamed him for having regulated every thing in his states except the succession to the throne, which he left at the mercy of faction; and for having multiplied those assemblies where the royal power is necessarily weakened by being divided, a policy unsuitable to the extent and condition of his empire. Nor is this censure without foundation. By his genius, his courage, his activity, and the skill with which he distributed rewards, he unquestionably surmounted all obstacles; but he unfortunately consolidated nothing; and hence, to succeed him, we do not say with glory, but with safety to the throne and to France, it would have been necessary to resemble him in many of his great qualities. But such a successor was nowhere to be found. Charlemagne was the last hero of his race; and as he took no effectual measures to consolidate the empire which he had established, it went to pieces not long after that disastrous day when his nephew Roland, "with all his peerage, fell by Fontarabia." His death happened on the 28th January 814, in the seventy-second year of his age, and the forty-seventh of his reign; and he was buried in the cathedral of Aix-la-Chapelle. In the latter part of last century his tomb was opened, and his body, clothed in the imperial robes, was found seated on a throne of state. The whole crumbled into dust on being touched; but the diamond clasp that fastened his mantle is still preserved at Vienna.

The works of Charlemagne are, 1. His *Capitularies*, first collected by Ansegise, abbot of St Wandrille, the best edition of which is that of Etienne Baluze, Paris, 1677, 2 vols. folio; 2. *Letters*, contained in the collection of D. Bouquet; 3. A *Grammar*, of which fragments are to be found in the *Polygraphia* of Trithemius; 4. His *Testament*, contained in Bouchel's *Bibliothèque du Droit Français*, tom. iii., printed at Paris, 1667, folio, 5. Some Latin poems, such as the *Epitaph of Pope Adrian*, and the *Song of Roland*; 6. The *Caroline Books*.

Of the more early historians of Charlemagne the principal is Eginhard. The details of his reign will be found under France and Italy.

CHARLEROI or Charleroy, a town on the Sambre, province Hainault, Belgium, 33 miles S. from Brussels. It was originally founded by Charles II. of Spain; was destroyed in 1795; attacked by Napoleon in 1815; and restored

and strengthened in the following year by the Duke of Wellington. It contains extensive manufactories of woollen stuffs, leather, ropes, and glass, besides several distilleries and sugar refineries. There are about 90 coal pits, 50 iron foundries, and 70 high furnaces in the vicinity. About 6000 of the inhabitants are employed in nail-making, and 8345 at the coal-mines of the district. The railways, which run to most of the important towns, and the Brussels and Charleroi canal, afford abundant means of transit. Pop. of the town 8080; of the arrondissement 141,107.

CHARLES MARTEL (i.e. *the Hammer*), a renowned conqueror in the early annals of France. He deposed and restored Chilperic, king of France; and had the entire government of the kingdom, first with the title of *Mayor of the Palace*, and afterwards as *Duke of France.* He was the first to check the victorious career of the Saracens, who had overrun Spain and France. He defeated them with great slaughter near Tours, A.D. 732. He died in 741. See FRANCE.

CHARLES *le Gros*, emperor of the west in 881, king of Italy and Suabia, is memorable for his reverse of fortune. He was dethroned at a diet held near Mentz, by the French, the Italians, and the Germans, in 887; after which he was obliged to subsist on the bounty of the archbishop of Mentz. He died in 888.

CHARLES V., emperor of Germany and king of Spain, was son of Philip archduke of Austria, and of Jane queen of Castile. He was born at Ghent on the 24th February 1500, and succeeded to the crown of Spain in 1517. Two years afterwards he was chosen emperor at Frankfort, upon the death of his grandfather Maximilian. He was a great warrior and politician; and his ambition prompted him to aspire to universal empire. He fought sixty battles, in most of which he was victorious. He took Francis I., the king of France, prisoner at the battle of Pavia, and afterwards sold him his liberty on very hard terms; yet when the people of Ghent subsequently revolted, he asked leave to pass through the dominions of Francis; and the generous king, so far from avenging the ill treatment he had experienced, received and attended Charles with the utmost pomp and magnificence. He sacked Rome, took the pope prisoner, and perpetrated cruelties which are said to have exceeded those committed by the northern barbarians; yet the pious emperor went into mourning on account of this conquest, forbade the ringing of bells, commanded processions to be made, and prayers to be offered up for the deliverance of the pope his prisoner; and at the same time forbore to inflict the slightest punishment on those who had treated the holy father and the holy see with such inhumanity. He is accused by some Catholic writers of favouring the Lutherans, whom he might easily have extirpated. But the truth is, he found his account in the divisions which that sect occasioned; and he never failed to take advantage of them, sometimes against the pope, sometimes against France, and at other times against the empire itself. He was a great traveller, and made fifty different journeys into Germany, Spain, Italy, Flanders, France, England, and Africa. Though he had been successful in many unjust enterprises, yet his last attempt on Metz, which he besieged with an army of 100,000 men, and which deserved to have succeeded, proved a total failure.

Vexed at the reverse of fortune which seemed to attend his latter days, and oppressed by sickness, which unfitted him any longer for holding the reins of government with steadiness, or guiding them with address, he resigned his dominions to his brother Ferdinand and his son Philip, and retired to the monastery of St Justus, near Placentia, in Estremadura.

About six months before his death, the gout, to which he had long been subject, after a longer intermission than usual, returned with a proportional increase of violence. His shattered constitution had not strength enough remaining to withstand such a shock. It enfeebled his mind as well as his body; and from this period we hardly discern any traces of that sound and masculine understanding which distinguished Charles among his contemporaries. An illiberal and timid superstition depressed his spirit. He had no relish for amusements of any kind; and endeavoured to conform, in his manner of living, to all the rigour of monastic austerity. He desired no other society than that of monks, and was almost continually employed in chanting with them the hymns of the missal. As an expiation for his sins, he gave himself the discipline in secret, with such severity, that the whip of cords which he employed as the instrument of his punishment was found, after his decease, tinged with his blood. Nor was he satisfied with these acts of mortification, which, however severe, were not unexampled. The timorous and distrustful solicitude which always accompanies superstition still continued to disquiet him, and, depreciating all that he had done, prompted him to aim at something extraordinary, some new and singular act of piety which would display his zeal, and merit the favour of Heaven. The act on which he fixed was as wild and uncommon as any that superstition ever suggested to a disordered fancy. He resolved to celebrate his own obsequies before his death. He ordered his tomb to be erected in the chapel of the monastery. His domestics marched thither in funeral procession, with black tapers in their hands; and he himself followed in his shroud. He was laid in his coffin with much solemnity. The service for the dead was chanted; and Charles joined in the prayers which were offered up for the rest of his soul, mingling his tears with those which his attendants shed, as if they had been celebrating a real funeral. The ceremony closed with sprinkling holy water on the coffin in the usual form, and, all the assistants retiring, the doors of the chapel were shut. Then Charles rose out of the coffin, and withdrew to his apartment, full of those awful sentiments which such a singular solemnity was calculated to inspire. But either the fatiguing length of the ceremony, or the impression which this image of death left on his mind, affected him so much that next day he was seized with a fever. His feeble frame could not long resist its violence; and he expired on the 21st of September, after a life of fifty-eight years, six months, and twenty-one days. (Robertson's *History of Charles V.*) See SPAIN.

CHARLES I. } kings of Britain. See BRITAIN.
CHARLES II. }

CHARLES XII., king of Sweden, born in 1682, and killed at Frederickshall in Norway in 1718. His military achievements, which astonished all Europe, and his character as a sovereign, form parts of the history of Sweden, and are given in the account of that country. In person he was tall and of a noble mien, had a fine open forehead, large blue eyes, flaxen hair, fair complexion, a handsome nose, but little beard, and an agreeable smile. His manners were harsh and austere, not to say savage; and with respect to religion, he was indifferent towards all, though exteriorly a Lutheran, and a strong believer in predestination. A few anecdotes will illustrate his character. No dangers, however great, made the least impression upon him. When a horse or two were killed under him at the battle of Narva in 1700, he leapt nimbly upon fresh ones, saying, "These people find me exercise." One day when he was dictating letters to a secretary, a bomb fell through the roof into the next room of the house where they were sitting. The secretary, terrified lest the house should come down upon them, let the pen drop out of his hand. "What is the matter?" said the king calmly. The secretary could only reply, "Ah, Sire, the bomb!" "The bomb!" said the king, "what has the bomb to do with what I am dictating to you? Go on."

He preserved more humanity than is usually found among conquerors. Once in the middle of an action, finding a young Swedish officer wounded and unable to march, he obliged the officer to take his horse, and continued to command his infantry on foot. One day, near Leipsic, a peasant threw himself at his feet, with a complaint against a grenadier, that he had robbed him of certain eatables provided for himself and his family. "Is it true," said Charles sternly, "that you have robbed this man?" The soldier replied, "Sir, I have not done near so much to this man as your majesty has done to his master; for you have taken from Augustus a kingdom, whereas I have only taken from this poor scoundrel a dinner." Charles made the peasant amends, and pardoned the soldier for his firmness: "However, my friend," said he to the grenadier, "you will do well to recollect, that if I took a kingdom from Augustus, I did not take it for myself."

CHARLES'S WAIN, in *Astronomy*, seven stars in the constellation called *Ursa Major* or the Great Bear.

CHARLESTON, a city and seaport, capital of a district of the same name in the state of South Carolina, North America, stands on a tongue of land formed by the junction of the Ashley and Cooper rivers. N. Lat. 32. 46. 33., W. Long. 79. 57. 27. The bay is a large estuary formed by the junction of the two rivers, and extends about 7 miles S.E. from Charleston to the ocean, having an average width of 2 miles. A sand-bar extends across its mouth, but there are several channel entrances, the deepest of which, passing close to Sullivan's Island, admits at high tide vessels drawing 16 feet of water. Cooper and Ashley rivers are both deep and capable of accommodating the largest class of vessels, the former being 1400, and the latter 2100 yards wide opposite the city. The harbour is open to easterly winds, and vessels are much exposed during storms from that quarter. The city is protected by Fort Moultrie on Sullivan's Island, and by Castle Pinchney and Fort Johnson, the former 2 miles and the latter 4 below the city.

Charleston, one of the oldest cities in the Union, was founded as early as 1672, and was first called Oyster-Point Town. It soon became a place of considerable trade, and was chartered as a city in 1783. The ground on which it is built is low, being only 8 or 9 feet above high tide, which rises here about 6 feet; and the city has several times suffered from inundations by the water of the harbour being driven up by violent winds. The city is divided into four wards, and is governed by a mayor and 12 aldermen. It is regularly laid out in parallel streets running E. and W. from the Cooper to the Ashley, and intersected by others at nearly right angles. The streets vary in width from 35 to 70 feet, the houses are neat and elegant, and mostly built of brick. The streets are lined with a tree termed the "Pride of India;" while elegant villas adorned with verandahs, and surrounded with orange trees, magnolias, and palmettoes, add much to the elegance and beauty of the city. Among the public buildings are the city hall, exchange, court-house, jail, two arsenals, custom-house, theatre, college buildings, and orphan asylum. The college, one of the most flourishing institutions of the southern states, was founded in 1785, and has a president and 6 professors, with (in 1850) 70 students. The medical college was founded in 1833, and in 1850 had 8 professors and 158 students. The literary and philosophical society has a fine collection of objects in natural history, &c.; and the academy of fine arts possesses some valuable paintings. The city library contains about 2400 volumes. Four daily, 4 weekly, 1 bi-monthly, and 3 monthly newspapers and periodicals are published in Charleston. The floating dry dock is considered one of the best in the Union. The South Carolina railway extends from Charleston to Augusta, 136 miles, and has numerous branches going off in different directions. A canal 22 miles long connects the harbour with the Santee river; and by means of the railways now in the course of construction it will communicate with the Mississippi and Ohio rivers. The staple exports of Charleston are rice and cotton. Of cotton the receipts from the interior in 1850 were 400,714 bales, and of sea-island 17,994 bales; the exports were 365,327 bales upland, and 16,437 sea-island; the receipts of rice amounted to 147,690 barrels, the exports to 134,417 barrels. In 1852, 6,587,764 lb. sea-island, and 122,785,275 lb. upland cotton, 33,185 tierces of rice, and 329,279 bushels rough rice were exported. Charleston carries on very little foreign traffic. Its principal trade is coastwise with New York, whence the commodities are shipped to other countries. For the year ending June 1850 only 351 vessels of 121,367 tons cleared, and 303 vessels of 96,619 tons entered from foreign ports. The registered shipping of the port at this period consisted of 15,377 tons, and the shipping employed in the coasting trade of 17,916. The population of Charleston in 1790 was 16,359; in 1800, 18,711; 1810, 24,711; 1820, 24,780; 1830, 30,289; 1840, 29,261; and in 1850, 42,985. This is exclusive of the suburb St Philip, which contains about 16,000 inhabitants.

CHARLESTOWN, a town of North America, state of Massachusetts, and county of Middlesex, situated on a peninsula formed by the Charles and Mystic rivers, one mile N. of Boston, with which, as also with Chelsea, Malden, &c. it is connected by bridges. It contains the Massachusetts state prison, lunatic asylum, town-hall, and United States navy-yard covering 60 acres of land, and which has a marine hospital, extensive warehouse, arsenal, and powder magazine. Breed's or Bunker's Hill stands close to the town, and has a granite obelisk commemorating the battle fought there June 17, 1775. Charlestown may be considered as a suburb of Boston. It is a place of considerable trade, and had in 1850 17,216 inhabitants.

CHARLETON, Walter (1619–1707), a learned English physician, and physician in ordinary to Charles I. and Charles II., was one of the first members of the Royal Society, and president of the College of Physicians. Having fallen into straitened circumstances he was obliged to retire to Jersey, where he died. He wrote several dissertations on medical and antiquarian subjects.

CHARLEVILLE, a remarkably handsome and well built town of France, on the left bank of the Meuse, department of Ardennes, arrondissement and one mile N. of the town of Mézières, with which it is connected by an avenue and suspension bridge. Since the end of the seventeenth century, when its fortifications were destroyed, it has become a thriving place, and has manufactures of nails, hardware, firearms, &c., and an active export trade in wine, spirits, coal, iron, and slates. It has tribunals of primary instance and commerce, a commodious port, theatre, public library of 24,000 volumes, and cabinet of natural history. The royal manufactory of arms, formerly established here, has been transferred to Tulle and Chatellerault. Pop. 9000.

Charleville, a town of Ireland, county of Cork, 34 miles N.N.W. of Cork, and 129½ from Dublin by the Great Southern and Western railway, on which it has a station. It is pleasantly situated, tolerably well built, and has a handsome Roman Catholic chapel, court-house, classical school, bridewell, dispensary, fever hospital, corn-mills, and some manufactures of blankets and leather. Previous to the Union it returned 2 members to the Irish parliament. Pop. (1851) 2685.

CHARLEVOIX, Pierre François Xavier de, a French Jesuit missionary, who has left laborious and minute accounts of his proceedings in North America. He was born in 1682, went to Quebec in 1720, explored Canada and St Domingo, and returned to France in 1722. His *Histoire de la Nouvelle France* contains good details regarding the French settlements in the new world. He also compiled an account of Japan, principally taken from Kœmp-

fer; and a history of St Domingo from the MSS. of another Jesuit, Bers; besides an account of Paraguay from similar materials. He died in 1761.

CHARLOTTENBURG, a town in the Prussian province of Brandenburg, government of Potsdam, and circle of Teltow, on the left bank of the Spree, 4 miles W. of Berlin. The town is handsome and well built, the streets are straight, and ornamented with rows of trees. There is a magnificent palace built by Frederick I. with finely laid out gardens, always open to the public, and much resorted to by parties from the capital. In a secluded part of the gardens there is an exquisite statue of the beautiful and unfortunate queen Louisa of Mecklenburg. Pop. (1849), including the military, 9213.

CHARLOTTESVILLE, a village in the state of Virginia, North America, capital of the county of Albemarle, on Moore's Creek, 2 miles from its entrance into the Rivanna river, 63 miles N.W. of Richmond. It is chiefly important as being the seat of the university of Virginia, founded in 1819, and which has a fine observatory, museums, library of 18,000 volumes, and about 400 students. Pop. about 1400.

CHARLOTTE-TOWN, the capital of Prince Edwards Island, stands on a gentle eminence on the N. bank of the Hillsborough river, near the south coast. The harbour is good and capacious. The town is well built, and has a court-house, barrack, fort, two churches, national school, &c. Pop. 4000.

CHARM (Latin *carmen*, a verse), is used to denote a magical power or spell, by which sorcerers and witches were supposed, with the assistance of the devil, to do wonderful things.

CHARNEL, or CHARNEL-HOUSE, a place under or near churches, where the bones of the dead are reposited. Anciently, a kind of portico or gallery, in or near a church-yard, over which the bones of the dead were laid after the flesh had been consumed.

CHAROLLES, a town of France, capital of an arrondissement of the same name, in the department of Saône-et-Loire, 30 miles W.N.W. of Mâcon. It has tribunals of primary instance and commerce, agricultural society, communal college, public library, manufactories of pottery ware, iron forges, and a considerable trade in corn, wine, cattle, and timber. It was the capital of Charolais, an old division of France which gave the title of Count to the eldest son of the Duke of Burgundy. The ruins of the count's castle occupy the summit of a hill in the immediate vicinity. Pop. (1851) 3427.

CHARON, in Grecian mythology, the son of Erebus and Nox, whose office it was to ferry the souls of the deceased over the waters of Acheron. For this service each soul was required to pay an obolus or danace; which coin was accordingly placed in the mouth of every corpse previous to burial.

CHARONDAS, a celebrated lawgiver, who legislated not only for his native Catana, but likewise for various cities of Magna Græcia. By some he is said to have been a disciple of Pythagoras, who flourished B.C. 540–510; and according to the common account (as given by Diodorus, xii.), he also drew up a code for the use of the Thurians; but this statement is scarcely admissible, since Thurii was not founded till the year 443, and it is known that the laws of Charondas were in use among the Rhegians till they were abolished by Anaxilaus, who reigned from B.C. 494 to 476. It is traditionally related that Charondas fell a sacrifice to one of his own laws, by which it was made a capital offence to appear armed in a public assembly. Hastening to quell a tumult on his return from a military expedition, his sword still hanging by his side, a citizen reminded him of his violation of the law; upon which Charondas exclaimed—"Then will I seal it with my blood," and immediately plunged the weapon into his breast. Fragments of his laws are given in Heyne's *Opuscula*, vol. ii.

CHARPENTIER, FRANÇOIS (1620–1702), dean of the French academy, was educated for the bar; but preferred the study of languages and antiquity to that of law. He was employed by Colbert in establishing his new Academy of Medals and Inscriptions; and was a principal contributor to the series of medals struck on occasion of the principal events which distinguished the reign of Louis XIV. His principal works are a *Life of Socrates*, a *Translation of the Cyropædia*, and a good collection of Ana.

CHARR. See ICHTHYOLOGY.

CHARRON, PIERRE, the author of a book on *Wisdom*, and *Les Trois Vérités*, was born at Paris in 1541. After having been advocate in the parliament of Paris for five or six years, he applied himself to divinity, and became so popular a preacher, that the bishops of several dioceses offered him the highest dignities in their gift. He died suddenly in the street at Paris, on the 16th of November 1603.

CHART, or SEA-CHART, an hydrographical map, or a projection of some part of the earth's superficies *in plano*, for the use of navigators. Charts differ very considerably from geographical or land-maps, which are of no use in navigation. Nor are sea-charts all of the same kind; some being what are called plane charts, others Mercator charts, and others globular charts.

Plane CHART is a representation of some part of the superficies of the terraqueous globe, in which the meridians are supposed parallel to each other, the parallels of latitude at equal distances, and consequently the degrees of latitude and longitude everywhere equal to each other.

Mercator's CHART is that where the meridians are straight lines, parallel to each other, and equidistant; the parallels also straight lines, and parallel to each other; but the distance between them increasing from the equinoctial towards either pole, in the ratio of the secant of the latitude to the radius.

Globular CHART, a meridional projection, in which the distance of the eye from the plane of the meridian, upon which the projection is made, is supposed to be equal to the sine of the angle 45°. This projection comes the nearest of all to the nature of the globe, because the meridians are placed at equal distances; the parallels also are nearly equidistant, and consequently the several parts of the earth have their proper proportion of magnitude, distance, and situation, nearly the same indeed as on the globe itself.

Hydrographic CHARTS, sheets of large paper on which several parts of the land and sea are described, with their respective coasts, harbours, sounds, flats, rocks, shelves, sands, and so forth, together with the longitude and latitude of each place, and the points of the compass.

Selenographic CHARTS, represent the spots, appearances, and maculæ of the moon.

Topographic CHARTS, draughts of small parts of the earth, or of particular places.

CHARTA, primarily signifies a sort of paper made of the plant *papyrus* or *biblus*.

CHARTER, MAGNA CHARTA. The word charter, from χάρτης, thick paper or parchment, came to be applied, from the substance on which it was written, to a document granted by a prince conferring or acknowledging privileges to be enjoyed by either the whole, or a portion of the people under his rule. In England, from the Conquest downwards, there was a struggle between those who sought to enforce the feudal exactions which the Normans had learned in France, and those who attempted to resist the innovation and hold to the old Saxon customs. If at first it was a contest between the monarch with his Norman followers on the one side, and the Saxon population on the other, the conditions had changed during the lapse of nearly a century and

a half preceding the reign of John, and the barons were so frequently incensed by the oppressions and exactions of the ambitious kings, to whose power they had contributed so much, that they joined in the general demand for "the good old laws of Edward the Confessor." Even so early as the reign of the Conqueror himself, there was a royal acknowledgment of franchises or liberties, and the charters, renewals, or confirmations granted by subsequent kings are inextricably numerous. Coke, without exhausting them, counts thirty-two. The Great Charter of King John has so conspicuous a place in history, not only from its comparative completeness, but because it was exacted by men with arms in their hands from a resisting king, and was thus an enforced stipulation likely to be rigidly interpreted, instead of a concession carelessly conceded and readily forgotten. A great many of the stipulations of the great charter refer to feudal exactions now so long obsolete that the restraints on them cease to be intelligible; and those who have looked at the "palladium of our liberties" expecting to find in it high-sounding definitions of freedom like those in modern continental declarations of right have been much disappointed. Even in the comparatively popular language of Blackstone, there is not much to convey a distinct expression to unprofessional modern readers.

"It fixed," he says, "the forfeiture of lands for felony in the same manner as it still remains; and prohibited for the future the grants of exclusive fisheries, and the erection of new bridges so as to oppress the neighbourhood. With respect to private rights, it established the testamentary power of the subject over part of his personal estate, the rest being distributed among his wife and children; it laid down the law of dower as it has continued ever since; and it prohibited the appeals of women, unless for the death of their husbands. In matters of public police and national concern, it enjoined an uniformity of weights and measures; gave new encouragements to commerce, by the protection of merchant strangers; and forbade the alienation of lands in mortmain. With regard to the administration of justice, besides prohibiting all denials or delays of it, it fixed the court of common pleas at Westminster, that the suitors might no longer be harassed with following the king's person in all his progresses; and at the same time brought the trial of issues home to the very doors of the freeholders, by directing assizes to be taken in the proper counties, and establishing annual circuits. It also corrected some abuses then incident to the trials by wager of law and of battle; directed the regular awarding of inquests for life or member; prohibited the king's inferior ministers from holding pleas of the crown, or trying any criminal charge, whereby many forfeitures might otherwise have unjustly accrued to the exchequer; and regulated the time and place of holding the inferior tribunals of justice, the county-court, sheriff's turn and court-leet. It confirmed and established the liberties of the city of London, and all other cities, boroughs, towns, and ports of the kingdom. And, lastly, it protected every individual of the nation in the free enjoyment of his life, his liberty, and his property, unless declared to be forfeited by the judgment of his peers, or the law of the land."

The material feature of the document is that so slightly referred to in the above extract, which says, "No freeman shall be taken or imprisoned, or be disseised of his freehold or liberties, or free customs, or be outlawed or exiled, or any otherwise damaged, nor will we pass upon him, nor send upon him, but by lawful judgment of his peers, or by the law of the land." In this stipulation there is inferred that supremacy of the fixed principles of the law over the will and power of the monarch, which has rendered the fanatical devotion of the English lawyers to their common law so justifiable; and as a farther security, the right of trial by peers or jurymen appointed a perpetual popular tribunal to check the official judges, should they be tempted to sell the liberties and privileges of the subject. Hallam, a very competent judge, says, "The institutions of positive law, the far more important changes which time has wrought in the order of society during 600 years subsequent to the Great Charter, have undoubtedly lessened its direct application to our present circumstances. But it is still the keystone of English liberty. All that has since been obtained is little more than a confirmation or commentary; and if every subsequent law were to be swept away, there would still remain the bold features that distinguish a free from a despotic monarchy."—(*Mid. Ages*, tit. ii. chap. viii.)

Exemplars of the Great Charter were preserved among the muniments of cathedrals, and in other places calculated to preserve public archives. The late record commission, when they published their edition of the statutes of the realm, were desirous to print the best authenticated version of the charter of King John; and they state, that "In Lincoln Cathedral, an original of the Great Charter of Liberties, granted by King John in the seventh year of his reign, is preserved in a perfect state. This charter appears to be of superior authority to either of the two charters of the same date preserved in the British Museum. From the contemporary indorsement of the word *Lincolina* on two folds of the charter, this may be presumed to be the charter transmitted by the hands of Hugh, the then bishop of Lincoln, who is one of the bishops named in the introductory clause."—(*Introduction*, xxix.)

Among the other concessions of a less comprehensive nature, the Charter of the Forest was deemed next in importance to Magna Charta. In nothing was the selfish rapacity of the Norman monarchs more conspicuous than in their relentless clearings of great districts of country for the establishment of forests or chases, where the sanctity of their field sports was protected with a strict legal severity not conceded to the protection of ordinary property and personal freedom. The Charter of the Forest imposed wholesome limits on such inroads, and hence, along with the Great Charter, it has been printed at the commencement of the English statutes. The position of these documents in a series of acts of parliament is not so anomalous as it might seem; for it would be very difficult to distinguish the charters from the earliest statutes, which were concessions or admissions granted by the monarch, on the requisition of the principal persons of the realm assembled together. Our statutes, indeed, still bear in their phraseology a testimony to this origin.

The early use of the word "charter," as a foundation of constitutional liberties, led to its being applied on various occasions to fundamental constitutional codes or rules of government adopted by various nations. The most memorable instance is the French *Charte*, containing the constitution of the French government, as adjusted at the restoration in 1815, and amended at the revolution of 1830, which was caused by an attempt of Charles X. to stretch one of its dubious clauses. See France.

From such public acts as Magna Charta, the concession of privileges by charter from the crown descended through various grades. Both in England and Scotland the privileges of municipal corporations were either conferred of old by charter, or presumed to have been so. (Municipal Corporations.) The power of the crown has in this form long virtually departed, but it is still competent to incorporate collective bodies with certain limited powers by royal charter; though, in general, it is deemed necessary when the powers might affect personal or public interests to secure them by act of parliament. (See Corporation.) Insidious privileges were sometimes granted by charter, and were among the objects of the attacks on the crown's power to grant monopolies in the seventeenth century.

By the practice of mimicking the usages of the sovereign through all grades of feudality, it became the custom for

every feudal lord or superior, high or low, when conceding any privilege as to his fief or landed property to do so by a charter. Thus, throughout the British empire, and in Scotland especially, one of the most ordinary deeds connected with the commerce in land, assumes to this day the shape of a concession of privileges by a sovereign or other high feudal lord to his vassal. One of the essential features which the student of Scottish law has to master in the practice of conveyancing, is the constitution of the charter. Although modern practice has ingrafted on it other classes of deeds, to suit the exigencies of the commerce in land, such as the disposition, the assignation, &c., yet "the charter" is the original source from which the spirit and tenor of the whole system of conveyancing are to be acquired. (J. H. B.)

Charter-Party, a written, or partly written and partly printed contract, by which a ship is let or hired for the conveyance of goods on a specified voyage, or for a definite term in some particular trade. By the terms of this contract the owners declare the ship to be "tight, staunch, strong, and every way fitted for the voyage;" and they are accordingly liable in damages to the merchant or charterer, if the ship be unseaworthy, or if they fail to provide her either with any necessary equipment, or with the clearances or other documents legally required for the voyage. The shipowners are further bound to have the vessel ready to receive her cargo at the stipulated time; and they are responsible for the proper stowage of the goods received on board. On the loading being completed, the vessel must proceed without delay to her appointed destination; and should she unnecessarily deviate from the regular course of the voyage (a proceeding which might vitiate the merchant's insurances), the owners are legally liable for whatever damages the merchant may prove that he has thereby sustained. On arrival at the port of destination the goods are to be delivered "agreeably to bills of lading," the responsibility of the shipowners in this particular being limited by the usual exception against loss or damage by "the act of God, the queen's enemies, fire, and all and every other dangers and accidents of the seas, rivers, and navigation of whatever nature and kind soever." The freight payable to the shipowners is the amount specified in the charter-party, which may in certain cases be either more or less than the rates mentioned in the bills of lading; the charterer having usually the right of sub-letting the ship in part or in whole to other shippers, on terms agreed upon between themselves, and which it is customary to specify in their separate bills of lading, without prejudice to the original agreement. In such cases, however, the shipowners' lien on the goods for freight extends only to the amount specified in the bills of lading; and they must look to the charterer personally for any further sum which may be due to them.

The charterer, on his part, is bound to furnish the cargo at the port of loading, and to take delivery of the same at the port of discharge within specified periods, which are usually called "laydays." He may detain the vessel for a certain fixed time beyond the stipulated laydays on payment of a specified sum as "demurrage" for each day the ship is so detained. The laydays commence on the ship being ready to load or to discharge, even although it may happen from the port being crowded, or from similar causes, that she cannot at the time be placed in a berth where it would be convenient or even practicable for the merchant to begin these operations.

The vessel is not bound to proceed nearer to her port of loading and discharging than "she may safely get;" and this is held to mean that she is not bound to go nearer to a loading port than to the point from which she can safely get away again *with her cargo on board.* The charterer, therefore, must pay the expense of necessary lighterage in loading or discharging, unless there be a specific agreement to the contrary.

It is usual to insert in charter-parties a clause by which the parties bind themselves to fulfil their contract under a specified sum as penalty for non-performance; but the amount of this penalty is not the absolute limit of the damages which either party may be entitled to recover under any of the other conditions which may have been violated. See Carrier. (J. W—K.)

CHARTISTS, the name of a party of political agitators in Great Britain, who sprung up about the year 1838, and whose views are developed in a document called the "People's Charter." As their leading principles they advocate universal suffrage, vote by ballot, annual parliaments, no property qualification, division of the kingdom into electoral districts so as to give uniform constituencies, and the payment of members. See Britain, vol. iv., p. 671.

CHARTOPHYLAX. See Chartulary.

CHARTRES, the capital of the department Eure-et-Loire, 55 miles S.W. from Paris, and connected with it by railway, stands on a slope skirted by the river Eure, which flows partly within and partly without the ramparts. The houses are antique and straggling; but there are four fine squares, in one of which, used as the herb-market, is an obelisk in memory of General Marceau. It is the seat of tribunals of the first instance and commerce; of a communal college and diocesan seminary; and has a weekly corn-market, which is well managed by a corporation of women. Its chief manufactures are woollens and leather. Its cathedral of Nôtre Dame, founded by Bishop Fulbert in 1269, is a vast Gothic edifice, and is reckoned one of the finest cathedrals in France. The churches of St Pierre and St André may also be noticed. Pop. (1851) 16,680.

Chartres was one of the principal towns of the Carmites, and by the Romans was called Autricum from the river Audura (Eure). From the Romans it passed into the hands of the Frankish kings, and was successively taken by Thierry II., king of Orleans and Bourgogne, and by the Normans, who burnt it in 852 and 872. It afterwards fell into the hands of the English, from whom it was again recovered in 1432. It was attacked unsuccessfully by the Protestants in 1568, and taken in 1591 by Henry IV., who was consecrated there three years afterwards. Since the time of Louis XIII. the title of Duke de Chartres has been hereditary in the family of Orleans.

CHARTREUSE, La Grande, a famous Carthusian monastery of France, department of Isère, 14 miles N. of Grenoble, occupying the summit of a steep rock in a wildly picturesque district, 4268 feet above the level of the sea. It was founded in 1084, but the present buildings have been erected since 1676. During the revolution the monks were driven out and their property confiscated and sold; but in 1826 it was restored to its original destination, and is still the capital of the Carthusian convents. See Carthusians.

From this mother convent all others of the same order took their name, among which was the Chartreuse of London, corruptly called the *Charterhouse.* This old monastery in 1611 was converted into a hospital for a master, preacher, second master, 40 boys, and 80 pensioners not under 50 years of age, and endowed with lands then worth about L.5000 a year. The boys receive instruction in the classics; and those sent to the university have an exhibition of L.20 a year for 8 years, and an immediate title to 9 church livings in the gift of the governors of the hospital, who are sixteen in number. The pensioners have provisions, fire, lodging, a gown of black cloth, and an allowance of money. They are presented by the governors in rotation.

CHARTULARY, Chartularius, an officer in the ancient Latin Church, who had the care of charters and papers relating to public affairs. He also presided in ecclesiastical judgments, in place of the pope. In the Greek Church the chartulary was called *chartophylax;* but his

office was there even more considerable. The word *chartulary* is also used for a record or register, as of a monastery.

CHARYBDIS. See SCYLLA.

CHASE, or CHACE, is a place of retreat for deer and wild beasts, of a middle kind between a forest and a park, being usually less than a forest and not possessed of so many privileges. The following history of the English chase is given by Mr Pennant (*British Zool.* i. 42): "At first the beasts of chase had this whole island for their range; they knew no other limits than the ocean, nor confessed any particular master. When the Saxons had established themselves in the heptarchy, they were reserved by each sovereign for his own particular diversion. Hunting and war in those uncivilized ages were the only employ of the great; their active but uncultivated minds being susceptible of no pleasures but those of a violent kind, such as gave exercise to their bodies, and prevented the pain of thinking.

"But as the Saxon kings only appropriated those lands to the use of forests which were unoccupied, so no individuals received any injury; but when the Conquest had settled the Norman line on the throne, this passion for the chase was carried to an excess which involved every civil right in a general ruin: it superseded the consideration of religion even in a superstitious age; the village communities, nay, even the most sacred edifices, were turned into one vast waste, to make room for animals, the objects of a lawless tyrant's pleasure. The New Forest in Hampshire is too trite an instance to be dwelt on; sanguinary laws were enacted to preserve the game; and in the reigns of William Rufus and Henry I. it was less criminal to destroy one of the human species than a beast of chase. Thus it continued while the Norman line filled the throne; but when the Saxon line was restored under Henry II. the rigour of the forest laws was immediately softened.

"When our barons began to form a power, they claimed a vast but more limited tract for a diversion that the English were always fond of. They were very jealous of any encroachments on their respective bounds, which were often the cause of deadly feuds. Such a one gave cause to the fatal battle of *Chevy-chase*, a fact which, though recorded only in a ballad, may, from what we know of the manners of the times, be founded on truth; not that it was attended with all the circumstances which the author of that natural but heroic composition has given it; for on that day neither a *Percy* nor a *Douglas* fell. Here the poet seems to have claimed his privilege, and mixed with this fray some of the events of the battle of *Otterbourne*.

"When property became happily more divided by the relaxation of the feudal tenures, those extensive hunting grounds became more limited; and as tillage and husbandry increased, the beasts of chase were obliged to give way to others more useful to the community. The vast tracts of land before dedicated to hunting were then contracted, and, in proportion as the useful arts gained ground, either lost their original destination, or gave rise to the invention of *parks*. Liberty and the arts seem coeval; for when once the latter got footing, the former protected the labours of the industrious from being ruined by the licentious sportsman, or being devoured by the objects of his diversion. For this reason the subjects of a despotic government still experience the inconveniences of vast wastes and forests, the terrors of the neighbouring husbandmen, while in our well-regulated monarchy very few chases remain. The English still indulge themselves in the pleasures of hunting, but confine the deer kind to parks, of which England boasts of more than any other kingdom in Europe. The laws allow every man his pleasure, but confine them in such bounds as to prevent them from being injurious to the meanest of the community. Before the Reformation the prelates seem to have guarded sufficiently against this want of amusement, the see of Norwich in particular being possessed about that time of thirteen parks."

CHASTELLET, MADAME DU, whose full name was *Gabrielle Emilie Le Tonnellier de Breteuil, Marquise du Chastellet*, has obtained celebrity by her translation of the *Principia* of Newton, as well as by being *l'Amie de Voltaire*. This accomplished lady was mistress of Latin, Italian, and English, and appears to have made great proficiency in mathematics. Her translation was considered worthy of the revision of Clairaut. She was also the author of *Institutions de Physique*, published in 1740, and so popular as to appear in a second edition at Amsterdam in 1742. The translation of Newton was a posthumous publication, and the labour bestowed on it is said to have caused her death, which took place at Luneville in 1749.

CHASTITY (*castitas*), a state of purity or freedom from unlawful sexual intercourse. By the Roman law homicide is justifiable in defence of a person's own chastity, or that of one's relations; and so also, according to Selden, stood the law in the Jewish republic.

CHATEAUBRIAND, FRANÇOIS AUGUSTE, VICOMTE DE, was born at St Malo, Brittany, in 1769. After studying at Dol and Rennes, he entered the army as a sub-lieutenant in 1786, and on the establishment of the Reign of Terror emigrated to America, where he remained till 1792. He returned to serve in the army of Condé; but having been wounded at the siege of Thionville, retired to England, where he published his *Essay on Revolutions.* A visit to the United States at this period made him acquainted with the phases of Indian life which are delineated in some of his tales. After the 18th Brumaire 1799 he returned to France, and became a contributor to the *Mercure.* His reputation as a writer was established in 1802 by the publication of the *Génie du Christianisme;* and in the following year he entered the diplomatic service of the First Consul, by whom he was sent as secretary to the French embassy at Rome. From Rome he went in an official capacity to Switzerland; but on the execution of the Duke d'Enghien he resigned his appointments and lived in retirement till the restoration. A part of the interval, however, was spent abroad in visiting the Holy Land. At Ghent he officiated as foreign minister to Louis XVIII., and in 1815 was elected a member of the Chamber of Peers. Under the Villèle administration he was sent as ambassador to London, and afterwards to the Congress of Verona, where he organized the French invasion of Spain, a measure which, when minister of foreign affairs, he had afterwards the principal responsibility of executing. In 1824 he was dismissed from office, and employed his pen in vigorously denouncing his former colleagues. Four years later, when his friends were for a short time restored to power, Chateaubriand was sent as ambassador to Rome, but again resigned on the formation of the Polignac ministry. On the outbreak of the revolution in 1830 he went to Paris, and delivered an oration in favour of the Duke of Bourdeaux. This was his last appearance personally in public. The rest of his life was spent in strict seclusion; but the keen political pamphlets which occasionally issued from his retreat wielded so great an influence over the minds of his countrymen that the government of Louis Philippe found it necessary to lay him under a brief arrest. He died in July 1848, after witnessing the second revolution of that year which ushered in the republic. His *Mémoires* were published after his death, and contain much curious information illustrative of the eventful times in which he lived, but are greatly marred by the tone of supercilious vanity which prevails throughout the whole. His collected works were published at Paris in 1826.

CHATEAUBRIANT, a town of France, capital of an arrondissement of the same name, in the department of Loire Inférieure, on the left bank of the Chere, 35 miles N.N.E. of Nantes. It takes its name from a castle, founded

in 1015, of which remains still exist. It has manufactures of woollen stuffs and confectionary, and some trade in iron, coal, wood, and corn. Pop. (1851) 4010.

CHATEAUDUN, a town of France, capital of an arrondissement of the same name in the department of Eure-et-Loire, 28 miles S.S.W. of Chartres. It stands on an eminence near the left bank of the Loire, and has remains of an old castle, a town-hall, communal college, public library, and manufactures of woollens and leather. It was almost entirely destroyed by fire in 1723. Pop. 6441.

CHATEAU-GONTIER, the capital of an arrondissement of the same name, in the department of Mayenne, France, on the right bank of the Mayenne, here crossed by a stone bridge, 17 miles S.S.E. of Laval. It has a fine Gothic church, communal college, three hospitals, agricultural society, public baths, extensive bleachfields, and manufactures of linen and woollen stuffs. It is the entrepot of a great part of the wine, slate, coal, &c. of the department. Pop. 6443.

CHATEAUROUX, the capital of the department of Indre, France, is situated in a fine plain on the left bank of the Indre, 63 miles S.E. of Tours. It is the seat of a court of assize, tribunals of primary instance and commerce, and has a castle, now used as the town-hall, a society of arts and agriculture, communal college, theatre, and public library. It is ill-built, with narrow filthy streets. The principal manufacture is woollens, in which a great part of its inhabitants are employed; and it has an active trade in woollen yarn, leather, iron, grain, cattle, &c. Pop. 14,276.

CHATEAU-THIERRY, a town of France, capital of an arrondissement of the same name in the department of Aisne, pleasantly situated on the right bank of the Marne, and connected with an extensive suburb on the opposite bank by a fine stone bridge of three arches. It is the seat of a tribunal of primary instance, and has a communal college, public library, and manufactures of linen, leather, and earthenware. It contains a marble statue erected to the memory of La Fontaine, who was born here, and whose house is still preserved. Pop. 5380.

CHATELLERAULT, a town of France, capital of an arrondissement of the same name, in the department of Vienne, on the right bank of the Vienne, here crossed by a handsome stone bridge, which connects it with a suburb on the opposite side of the river, 24 miles N.N.E. of Poitiers. Pop. (1851) 11,959. It stands in a fertile valley, and has several fine promenades, but is ill-built and dirty. It has tribunals of primary instance and commerce, a fine Gothic church, public fountain, communal college, exchange, hospital, society of agriculture, and a theatre. It is one of the chief seats of the manufacture of cutlery in France; and has a royal manufactory of swords and bayonets, established in 1820. It has a large trade in wines, dried fruits, slates, iron, corn, hemp, timber, &c. James Hamilton, second Earl of Arran, was created Duke of Chatellerault in 1548 by Henri II.; and the title is still in the family.

CHATHAM, a fortified town and royal dockyard on the Medway (which at Rochester bridge is a considerable tidal river), Kent, 30 miles from London. It includes the village of Brompton, between which and Rochester it forms a continuous, narrow, and irregular street. The houses are ill-built, many of them being only of wood. It contains two Established and seven Dissenting churches, five schools (including a ragged school), and a mechanics' institute. Its charities included several ancient hospitals, which have now been superseded; but there is still maintained a military lunatic asylum and several smaller establishments. The "Chest," for disabled seamen, established by Queen Elizabeth, who also founded the dockyard, has been removed to Greenwich. An account of the dock will be found under the article DOCKYARD. Chatham returns one member to the imperial parliament. Pop. (1851) 28,424.

CHATHAM ISLANDS, a group in the South Pacific, E. of New Zealand, lying between S. Lat. 43. 40. and 45. 20., and W. Long. 176. 10. and 177. 20. It consists of three islands, a large one called Ware-Kauri, or Chatham Island, a smaller one, Rangi-Haute, or Pitt's Island, and a third, Rangatira, or South-east Island. Chatham Island, according to Dieffenbach, contains an area of 305,280 acres; of which, however, 57,600 acres are lakes and lagoons. In the centre is a large lake called Tewanga, about 25 miles long, and 6 or 7 broad, and surrounded on all sides by hills either wooded or boggy. Its water is slightly brackish, probably from infiltration. Occasionally it bursts its barriers and empties itself into the sea. The southern part of the island has an undulating surface, and is either covered with an open forest or with high ferns. In general the soil is extremely fertile, and where naturally drained, a rich vegetation of fern and flax (*Phormium tenax*) has sprung up, giving firmness to the soil and yielding a rich harvest to the planter. On the N.W. are a number of conical hills of basalt, which are surrounded by oases of fertile soil. On the western side is a large bay called Waitang Bay, well sheltered by projecting creeks, and affording excellent anchorage. Into this bay the river Mangatu falls, and is navigable for 3 miles from its mouth. The climate is very mild, in winter varying only from 45° to 60°. The changes of temperature are less sudden than in New Zealand. The natives cultivate potatoes, turnips, cabbages, taro (esculent *arum*), tobacco, and pumpkins. Wheat, sown by the sealers, grows wild on Pitt's Island. The trees and shrubs resemble those of New Zealand. The rat is the only quadruped; but ducks, snipes, plovers, curlews, red bills, sand larks, and parroquets, abound. Fish are abundant on the coast. Both spermaceti and black whales have been seen. Pitt's Island is about 12 miles long and 8 broad, has no harbour, and is inhabited only by a few aborigines.

These islands were discovered in 1791 by Lieut. Broughton, who gave them the name of Chatham, from the brig which he commanded. The aborigines who then inhabited them have been since enslaved by two tribes of New Zealanders, and their numbers reduced from 1200 to 90, by the oppressive labour exacted from them. Geologically speaking, the islands seem to belong to New Zealand; and it is said that soundings can be obtained between the two groups.

CHATILLON-SUR-SEINE, the capital of the arrondissement of Chatillon, in the department of Côte d'Or, France, on both sides of the Seine, 46 miles N.N.W. of Dijon. It is a neat well-built town, and has a magnificent castle, hospital, communal college, public library, and some fine promenades. In February 1814 a conference was held here between Napoleon and the allies. Pop. 4866.

CHATRE, LA, a pleasantly situated and well-built town of France, capital of an arrondissement of the same name, in the department of Indre, 22 miles S.E. of Chateauroux. It has an old castle, a fine church, communal college, manufactures of woollens and leather, and some trade in cattle, wool, hides, and chestnuts. Pop. 4889.

CHATSWORTH, the seat of the Duke of Devonshire, one of the most splendid private residences in England, is in the county of Derby, on the Derwent, 3½ miles N.E. of Bakewell. The present mansion was erected by the first duke of Devonshire in 1706, on the site of a former mansion built by Sir William Cavendish about the middle of the sixteenth century, and in which Mary Queen of Scotland was imprisoned for 13 years. The building is in the Ionic style, composed of four nearly equal sides, surrounding an open quadrangular court with a fountain in the centre. A wing and other additions have been made to it since 1820. Chatsworth contains some beautiful wood carvings by Gibbons and Watson, and several exquisite

pieces of sculpture by Canova, Thorwaldsen, Chantrey, Wyatt, &c. The park is about 9 miles in circuit, and the gardens are among the most celebrated in the kingdom. The conservatory, 300 feet long, 145 feet broad, and 67 feet high, is unequalled by any in Europe, and the water-works are only surpassed by those of Versailles.

CHATTAOOCHEE, a river of North America, United States, rises in the Appalachian Mountains, forming for a great part of its course the boundary between Georgia and Alabama, and after a course of nearly 400 miles unites with the Flint river to form the Appalachicola. It is navigable for steam-boats to Columbus.

CHATTELS, a Norman term, under which were anciently comprehended all moveable goods, those immoveable being termed *fief* or *fee*. In modern usage it includes all goods, moveable or immoveable, except such as are in the nature of freehold.

CHATTERTON, Thomas, a highly-gifted but ill-starred poet, was born at Bristol, November 20, 1752. His father, who had been originally an usher in a classical academy, and ultimately became master of the free school of Bristol, died three months before his son was born. At the early age of five the future poet was sent to the school in which his father had latterly taught; but so far was he from giving any indication of talent, that he was regarded alike by his teachers and his fellow pupils as an incorrigible dunce. At the end of a year and a half he was withdrawn from school, without having mastered the letters of the alphabet. Upon his mother now devolved the care of educating him. She happened to have in her possession an old black-letter manuscript, from which she proceeded to teach him the alphabet. His progress now became as rapid as it had formerly been slow. He very soon learned to read, and he had hardly mastered this accomplishment when he was visited by dreams of future distinction. When asked by a manufacturer, who had given him a small present of china-ware, what device he would like to have painted on it, he replied, "Paint me an angel with wings, and a trumpet to trumpet my name over the world." In 1760, before he had quite attained his eighth year, he became a pupil of Colston's charity school, at which he remained till 1767. During this period he made rapid progress in the branches taught at that institution, and distinguished himself besides by his poetical attempts, which were generally of a satiric tendency. By far the most remarkable of these youthful productions is the *Hymn for Christmas Day*. If we contrast the harmony and ease of expression displayed in this poem with the boyhood and inexperience of the author, we must pronounce it astonishing. During these seven years of his life, he was for the most part thoughtful and reserved, took no interest or share in boyish sports, was subject to fits of melancholy, and spent all his spare time in miscellaneous reading.

On leaving Colston's school, he was apprenticed to a scrivener in his native city. Though he was now compelled to perform the most menial offices, and was kept hard at work for twelve hours of the day, he nevertheless found time to amass great stores of knowledge in his favourite pursuits of heraldry and antiquities. The results of these studies he next year turned to account, by beginning a series of literary impositions, unparalleled in the history of letters. In 1768, a new bridge was opened at Bristol. Chatterton sent to the editor of a local newspaper a minute account of the ceremonies which had inaugurated the opening of the old bridge, as described in an ancient manuscript, which he said he had found in an old coffer in the church of St Mary Redcliffe. To a pewterer of the town, by name Burgum, who was ambitious of heraldic honours, he gave a long pedigree, tracing his genealogy from the times of the Norman Conquest, and his connexion with the noble family of De Bergham. To a theologian of Bristol he gave a fragment of a sermon on the divinity of the Holy Spirit, written by Thomas Rowley a monk of the 15th century; and to the historian of the city he supplied an account of all the churches of Bristol as they existed three hundred years before, with a minute description and plans of the castle, likewise purporting to be the work of Rowley. To Horace Walpole, who was at that time writing the history of British painters, he sent an account of the eminent "carvellers and peyncters who once flourished in Bristol." The skill with which all these forgeries were conducted was such, that not one of the Bristol literati entertained a suspicion of their genuineness, and Walpole himself was for a time deceived. To this must be attributed the coldness with which he regarded Chatterton during his life, and the bitterness with which he treated his memory after he was dead. Walpole's own forgeries, ingenious as they were, had been far too easily detected and too bitterly exposed for him not to view with distrust the similar attempts of any one else. Accordingly, when he received from the scrivener's apprentice of Bristol a roll of manuscript purporting to have been found in "Canynge's cofre" in the tower of St Mary Redcliffe, his suspicions were awakened; but, finding himself unable to pronounce a verdict on the matter, he called in the assistance of the poets Gray and Mason. After a careful scrutiny, Gray decided that the Rowley poems were forgeries, and in this decision he was completely borne out by Mason. Walpole had given a promise to assist the unknown and unbefriended antiquarian of Bristol; but his vanity had been wounded, and from this time he turned a deaf ear to all Chatterton's solicitations. He even refused to return the young poet his manuscripts, and it was only after the threat of an action at law that he restored them without a word of comment or encouragement. This silence provoked Chatterton, who avenged himself by a bitterly satirical attack on the cowardice and unworthiness of Walpole's conduct. The controversy soon began to attract considerable attention in London; and many persons, strongly convinced of the genuineness of the Rowley poems, undertook their defence, though with more zeal than success. Evidence, however, stronger than any of the moral evidence adduced on either side, was brought forward some years after Chatterton's death by Warton, Tyrwhit, Malone, and others of the more acute antiquarians of the day, which ought to have set the question at rest for ever. As late as 1834, however, a "Vindication" of Chatterton appeared, which the most partial of critics were obliged to pronounce completely unsuccessful. Meanwhile, without entering at all into the question of the moral guilt which has been imputed to Chatterton, we can only regret that he so sadly misdirected a genius that might have made his name respected as a benefactor of the human race, and earned for him a high place among the poets of England.

In the meantime the poet was working busily at his Rowley manuscripts. He slept little and wrote much during the night, especially if the moon were up; for he believed that the influence of that planet inspired him for his work. His eccentricities, combined with his sceptical views on religious matters, induced his master to break his indentures; and in 1770, Chatterton, without friends or introductions, set off to seek his fortune in London. His prospects at first were sufficiently bright, and he used laughingly to observe, that if all other means of subsistence failed, he would become a Methodist preacher. He began his literary career in the metropolis by contributing to various magazines and reviews. He likewise wrote political letters which gained for him both money and repute, besides sermons for dull clergymen, and burlettas for Vauxhall. By these and such means he was enabled for a while not only to maintain himself, but to re-

Chaucer. mit small sums to his mother and sister in his native town. But persecution followed him wherever he went, and his unconquerable pride would never allow him to vindicate himself in the manner that his better judgment might have suggested. For five months he maintained the desperate struggle, confiding to no one the history of his wrongs and sufferings. At the end of that period, finding himself utterly destitute, and without the prospect either of present relief or future success, he tore into shreds all his manuscripts, and after spending three days without food, bought with his last penny a little arsenic. On the following morning he was found dead in his miserable garret, and that same night was interred in the pauper burying-ground of Shoe-Lane.

Though Chatterton was below the middle height, his bearing was proud and manly. His eyes, like Lord Byron's, were gray; and, as was also the case with that poet, one of them was more brilliant than the other. Posterity has granted to him the meed of honour which his own generation withheld from him. Byron has praised him; Shelley has acknowledged his "solemn agency;" Wordsworth has thought of him as "the marvellous boy, the sleepless soul that perished in his pride;" Coleridge has apostrophized him in a pathetic monody; Keats has dedicated Endymion to his memory; and Alfred de Vigny has made his history and character the subject of one of his most interesting dramas. (J.C—L.)

CHAUCER, Geoffrey, who has been styled the Father of English poetry, has had many biographers, but much of his history is involved in considerable obscurity. The year 1328 has been usually assigned as the date of his birth, upon the authority of an inscription on his tombstone, in which he is said to have died in 1400, aged seventy-two. This inscription, however, was not placed on his tomb till the middle of the sixteenth century; and some doubt of its correctness has been expressed in consequence of Chaucer's deposition as a witness in October 1386, in which he states himself then to have been "forty years and upwards," and which, if strictly correct, would place his birth about 1345. We are certain, however, from his own words, that he was born in London; but with regard to his descent and parentage there is absolutely nothing known. Leland says he was *nobili loco natus;* but Speght, in 1598, informs us, that "in the opinion of some heralds, hee descended not of any great house, which they gather by his armes." This, as an old writer observes, "is a slender conjecture," yet not more so than Speght's supposition that his father was Richard Chaucer, a vintner, who died in 1348; while Pitts says that he was the son of a knight. It may also be noticed that there was a Robert Chaucer connected with the royal household of Edward II. who perhaps may have stood in that relationship. (*Rot. Scot.*) Leland, who lived in the reign of Henry VIII., asserts that he studied at Oxford; while his signature "Philogenet of Cambridge, Clerk," affixed to one of his early pieces, has been brought forward as more direct proof that he received his education at the latter university. Some of his biographers very gravely assure us that he was first at Cambridge, and then completed his studies at Oxford; after which they say he went on his travels through France and the Netherlands. The next statement is, that he was a member of the Inner Temple, and that whilst there he was fined "two shillings for beating a Franciscane frier in Fleet Street."

Without stopping to consider the probability of these several points, we may observe, that frequent mention of Chaucer, during the more advanced period of his life, occurs in various public instruments; most of which are printed in the Appendix to Mr Godwin's life of the poet. The first direct information we possess regarding his history is, that, in the autumn of 1359, he was in the army with which Edward III. invaded France. This fact we learn from his own deposition, which further states that he was made prisoner by the French near the town of Retters during that expedition; but we are not informed at what time he was ransomed and returned to England, although we may conclude that he never resumed the profession of arms. The next notice that has been discovered shows that he had attracted the regard of the English monarch, and that he was an attendant on the king's person. It is a patent in 1367, by which Edward the Third grants Chaucer an annuity of twenty marks, by the title of 'dilectus vallettus noster,' our valet or yeoman, in consideration of his former and expected services. According to Tyrwhitt, this designation was the intermediate rank between *squier* and *grome;* and this annuity may be reckoned in our present money at two hundred pounds. In his poem of the Dream, or the Complaint of the Black Knight, written before this time, the poet is supposed to allude to the nuptials of his munificent patron John of Gaunt, with Blanche, heiress of Lancaster. The same poem contains an allusion to the lady whom Chaucer himself afterwards married, although the time of his marriage is somewhat uncertain; but it is admitted that by this alliance he became eventually related to his illustrious patron.

In June 1370, it appears that Chaucer was abroad in the king's service; and on the 12th November 1372, being at that time one of the king's esquires, "scutifer noster," he was joined in a commission with two citizens of Genoa, to treat with the Duke and Duchess of Genoa, for the purpose of fixing upon some place on the coast of England where the Genoese might form a commercial establishment. It was at this time he enjoyed the opportunity of visiting Petrarch, if his visit to that illustrious poet ever took place, which, however pleasing to the imagination, is somewhat doubtful; as the passage in his Canterbury Tales, upon which his supposed conference with the "worthy clerk of Padua" is founded, is susceptible of a different interpretation. The next notice of Chaucer is, that on the 23d of April 1374, he obtained a grant for life of a pitcher of wine daily, to be received from the hands of the king's butler in the port of London. On the 8th June 1374 he was appointed comptroller of the customs, and subsidy of wools, &c. in the port of London, during the king's pleasure; but the patent contains the following injunction, "so that the said Geoffrey write with his own hand his rolls touching the said office, and continually reside there, and do and execute all things pertaining to the said office in his own person, and not by substitute." The reason of such an express injunction is not known, and it is possible that his majesty may have been insensible of his poetical talents, although this attendance on his official duties seems to have had no prejudicial effect on his genius, as the composition of his House of Fame is assigned to the same period. In November 1375, the wardship of Edmond, son and heir of Edmond Staplegate of Kent, was granted to Chaucer, for which he received L. 104; and in the following year, another grant, to the value of L. 71. 4s. 6d. connected with his office of comptroller of the customs. In February 1377 Chaucer was joined with Sir Guichard d'Angle, afterwards Earl of Huntingdon, and Sir Richard Sturry, to negotiate a secret treaty respecting the marriage of Richard, prince of Wales, with Mary, daughter of the king of France. His employment in foreign missions shows that Chaucer had established a personal and political character of some importance; and the emoluments which he received enabled him to live in a state of dignity and hospitality that was in accordance with his natural sociality of disposition.

The reign of his successor was, on the whole, not so propitious to the poet. On the accession of Richard the

Second, the annuity of twenty marks was indeed confirmed to him, and his grant of wine was replaced by an equivalent annuity of other twenty marks. He also retained the situation of comptroller of the customs and subsidies, which Edward the Third bestowed on him; but he was doomed to experience a reverse of fortune, in some measure connected with the decline of John of Gaunt's influence at court. The immediate cause of this reverse is said to have been his connection with a political party, in some disputes between the court and the city of London, in the year 1384. This party was headed by John of Northampton, an opulent merchant, who had been mayor, and was attached to the religious tenets of Wykliffe, and to the political interests of John of Gaunt. The result was, that Chaucer was compelled to fly the kingdom; and he retired first to Hainault, then to France, and finally to Zealand. How long he remained abroad is uncertain; but we find that Chaucer was elected a knight of the shire for the county of Kent in the parliament which met on the 1st October 1386. Whilst attending his parliamentary duties, he was examined at Westminster, on the 15th of October, as a witness "in the court of chivalry," in the great cause between Sir Richard Scrope and Sir Robert Grosvenor, when he made the deposition to which we have already alluded, the substance of which, in as far as relates to himself, is as follows; "Geoffrey Chaucer, Esquire, of the age of forty and upwards, armed twenty-seven years, being asked whether the arms, *azure*, a bend *or*, belonged to Sir Richard Scrope, said Yes; for he saw him so armed in France before the town of Retters, and Sir Henry Scrope armed in the same arms with a white label, and with banner; and the said Richard armed in the entire arms, and so during the whole expedition, untill the said Geoffrey was taken."

Whatever may be the date of Chaucer's return to England, we have his own testimony that he fled to avoid being examined in relation to certain disturbances; and that after his return he was arrested and confined to the Tower of London. That he was deprived of his comptrollership is also evident, as other persons are named as holding them in December 1386. During his imprisonment he commenced his Testament of Love, an allegorical prose composition, in imitation of Boethius' *De Consolatione Philosophiæ*, in which he feelingly laments his own situation, "berafte out of dignitie of office, in which he had made a gatheringe of worldly goodes;" and "enduring penance in this dark prison, caitifned from frendship and acquaintance, and forsaken of al that any word dare speak." As the price of his release, it is said, he was obliged to make a confession respecting the conspiracy in which he had been implicated. In May 1388 he found it necessary to apply for permission to surrender his two grants of twenty marks each in favour of one John Scalby. After this he is said to have retired to Woodstock, and employed himself in revising and correcting his writings, and enjoying the calm pleasures of rural contemplation, amidst the scenes which inspired his youthful genius. The composition of his Canterbury Tales is usually assigned to this period; when, though long past the prime of life, his mental powers must have been in their fullest vigour.

In 1389 the Duke of Lancaster having returned from Spain, and resumed his influence at court, it was probably through his influence that, on the 12th July 1390, Chaucer was appointed to the office of clerk of the king's works, the duties of which he was permitted to execute by deputy, with a salary of two shillings per diem. In this office, however, he seems to have been superseded in the course of the following year; but, on the 28th of February 1394, he obtained a grant of twenty pounds yearly for life. On the 4th May 1398, letters of protection were granted him for the space of two years. On the 13th October in the same year he obtained another grant of wine, being one tun yearly during his life.

Henry the Fourth, the son of his great patron the Duke of Lancaster, ascended the throne in 1399; and from him Chaucer had his annuity of twenty pounds confirmed, with the additional sum of forty marks yearly. The last record of Chaucer that has been discovered is a lease of a tenement in the garden of the chapel of the Blessed Mary of Westminster, dated on Christmas eve 1399. But the poet was not privileged to benefit long by these grants, as his death is said to have occurred at London on the 25th October 1400, at the age of seventy-two. The chief evidence on which the date of his decease rests is the inscription on his tomb, which was erected in the year 1556, by Nicholas Brigham, a gentleman of Oxford, an ardent admirer of the great English poet, and who no doubt had sufficient grounds, either from a previous inscription, or other information, for fixing the date. Chaucer lies interred in the south cross aisle of Westminster Abbey, in a place consecrated to the poetical genius of England.

Such is a brief abstract of nearly every fact relating to Chaucer that has been discovered; and upon which, aided by ample conjectural inferences, Mr Godwin constructed a life of the poet, which extends to two large volumes in 4to, and was reprinted in four vols. 8vo. Besides the Memoir by Sir Harris Nicolas, contained in his valuable historical and genealogical notes to the Scrope and Grosvenor Roll, recently printed, the curious reader is referred to the Reverend Mr Todd's "Illustrations of the Lives and Writings of Gower and Chaucer." Lond. 1810, 8vo.

Chaucer's works have been preserved in a variety of early manuscripts, which attest their continued popularity, and have been very frequently printed. One of the earlier productions of Caxton's press is an edition of the Canterbury Tales, without date, but printed about 1475. He also published a second edition, six years after the first, on being informed of the imperfections of that edition. It may be worthy of mention, in proof of Chaucer's popularity in Scotland, that one of the earliest specimens of the Scottish press was an edition of his Complaynt of the Black Knight, which was printed at Edinburgh, by Chepman and Myllar, in 1508, under the title of "The Maying or Disport of Chaucer." The first collected edition of his works was edited by William Thynne, and printed by Godfrey in 1532. They passed through several subsequent editions during the sixteenth and seventeenth centuries, besides later republications. The edition of the Canterbury Tales edited by Thomas Tyrwhitt, one of the most learned and accomplished of scholars whose attention had been directed to old English literature during the last century, is worthy of the highest commendation for accuracy and critical acumen. It was printed at London 1775, in 5 vols. 8vo, and reprinted at Oxford 1798, in 2 vols. 4to, and also more recently in London in its original form. A complete edition of Chaucer's works, from a collation of the earlier MSS. would be a most important addition to old English literature.

Chaucer's merits as a poet are of no ordinary kind; but in considering his poetical character, it is necessary to attend to the age in which he lived, in order to ascertain to what extent he may be said to have improved our language and versification. Chaucer himself, while he exposes the absurdity of his countrymen, like Gower, writing in a foreign language, seems to have entertained no very exalted idea of the vernacular tongue. During the thirteenth and fourteenth centuries there had been several English poets whose remains are interesting chiefly for their antiquity; but it remained as a distinction for the reign of Edward the Third to produce works which tend-

ed to exalt and fix the standard of our present language. In our veneration for Chaucer, however, too much influence in this respect has been attributed exclusively to his writings. It was the policy of the English monarch, rather than the poetical genius of Chaucer, which gave importance and dignity to the language, by causing it to be spoken at court, and to be substituted in all public and judicial proceedings, instead of the Norman-French, which had been introduced at the Conquest in 1066, and which had continued to be employed for nearly three centuries. Among the eminent men who adorned the reign of Edward the Third, the first in priority of date is Langland, the reputed author of the Visions of Piers Plowman. In his Visions, which are written in very obscure alliterative language, the author's object was to expose the abuses which then prevailed, and to bring about a reform in the morals both of the clergy and aristocracy. To accomplish this, with striking originality in his character as a moral satirist he depicts the various orders of society, and inveighs with great boldness against the depraved conduct of the clergy, and the corruptions of the papal government. The composition of this work has been fixed to the year 1362; and although the satire is considerably affected by the general personification in which the author indulged, there can be little doubt that the Visions contributed to improve the moral feelings of his contemporaries; and if his work had no beneficial effect upon the literature of the time, it at least remains as a monument of true poetical genius.

Another poet of distinction, contemporary with Chaucer, was John Gower. He is generally allowed to have been a man of extensive learning, but not of much natural genius. In fact his claims as an English poet are considerably lessened, as his French ballads are among his best productions; and one of his great works, the *Vox Clamantis,* is in Latin. Neither is Laurence Minot, who wrote various narrative ballads on the subject of the Wars of Edward the Third, entitled to any very marked distinction as an original writer.

Chaucer may have been known as a poet at the time Langland's Visions were written; but his greatest work is at least twenty years later in date. His chief merit in regard to versification consisted in rendering it more natural, regular, and comprehensive, by discarding alliteration, and by reducing the irregular Alexandrine metre to the heroic measure in an uniform and equal number of syllables. This adoption of the decasyllabic couplet has been used by nearly every great English poet from Spenser to Byron, who declared it to be " the best adapted measure to our language." In the structure of his verse generally, when compared with some previous writers, or with the numerous class of English metrical romances, there will not be found any essential distinction. But in contributing to the improvement of the English language, perhaps no author ought to be put into competition with the illustrious reformer Wykliffe. In addressing the different classes of society, he was obliged to use the vernacular dialect; and he inveighed against the corruptions of the time, not under the veil of cold allegorical personification, but in a bold and open manner, which must have been productive of important consequences in exciting the intellectual energies of the people. The extent and variety of knowledge he displayed far exceeded that of most of his contemporaries; and, being persuaded that the surest mode of enlightening the people would be the perusal of the Scriptures in their own tongue (although at the time it was affirmed by illiterate ecclesiastics to be heresy to speak of the Holy Scriptures in English), he accomplished a translation, which of itself, in a literary point of view, is sufficient to have immortalized his name.

Chaucer's writings partake much of his own personal character and spirit, as influenced by his intercourse with the world and his employment in public affairs. If his writings had not much influence upon the moral feelings of his contemporaries, they had at least a most important influence upon the literature of his country. But while his more immediate followers imitated the peculiarities of his " ornate" style and manner, they suffered his spirit and grace to evaporate; their chief object being an accumulation of ornament and an exuberance of diction to which every thing else was subservient. It is sufficiently remarkable, that during the greater part of Chaucer's poetical career, he contented himself with transferring into our language the most popular works of contemporary French and Italian writers, but in a manner which gives them the character of original productions rather than that of translations. In these earlier works there is elegance of fancy and picturesqueness of description; but all the grace and beauty of his allegorical compositions fall infinitely short of his power of delineating living character, as displayed in his immortal work the Canterbury Tales.

In this work, the idea of which was no doubt derived from Boccaccio, he brings together a motley crew of " syndry folke," who " in felowshyp" are travelling together on a pilgrimage to the shrine of St Thomas of Becket, to Canterbury; and, as the means of affording instruction and amusement, they agree, each of them in their turn, to relate a story, the details of which, with the incidents that happen, and, above all, the description of the character and manners of the persons themselves who are thus assembled, form a picture of life and manners altogether unrivalled. Nothing can exceed the skill shown in the general prologue, in which the habits of life and peculiarities of disposition of the different pilgrims are so singularly and so strikingly contrasted, with a rich vein of humour, and great discrimination of human nature.

We cannot do better than conclude with an extract from the work of an eminent contemporary, who has shown himself to be in every respect a master in the art of poetical criticism.

" Chaucer's forte," says Mr Campbell, " is description; much of his moral reflection is superfluous; none of his characteristic painting. His men and women are not mere ladies and gentlemen, like those who furnish apologies for Boccaccio's stories. They rise before us minutely traced, profusely varied, and strongly discriminated. Their features and casual manners seem to have an amusing congruity with their moral characters. He notices minute circumstances as if by chance; but every touch has its effect to our conception so distinctly that we seem to live and travel with his personages throughout the journey.

" What an intimate scene of English life in the fourteenth century do we enjoy in those tales, beyond what history displays by glimpses, through the stormy atmosphere of her scenes, or the antiquarian can discover by the cold light of his researches! Our ancestors are restored to us, not as phantoms from the field of battle, or the scaffold, but in the full enjoyment of their social existence. After four hundred years have closed over the mirthful features which formed the living originals of the poet's descriptions, his pages impress the fancy with the momentary credence that they are still alive; as if Time had rebuilt his ruins, and were re-acting the lost scenes of existence." *Specimens of the British Poets*, vol. ii. p. 21. (D. L.)

CHAUD MELLE, a term in the ancient law of Scotland, applied to a homicide committed in heat of blood or passion.

CHAUDES AIGUES, an old rustic-looking town of France, with about 1500 inhabitants, in the department of Cantal, arrondissement and 17 miles S.S.W. of St Flour. It is celebrated for hot mineral springs, varying in tempera-

ture from 135° to 177° Fahr.; and extensively used for baths, washing wool, and warming the houses of the town.

CHAUMONT, a town of France, capital of an arrondissement of the same name, and of the department of Haute Marne, on an eminence between the Marne and the Suize, 19 miles N.N.W. of Langres. It is the seat of tribunals of primary instance and commerce, is tolerably well built, and has an elegant town-hall, a palace of justice, communal college, theatre, public library, and museum. It has manufactures of coarse woollens, druggets, hosiery, gloves, and a considerable trade in iron and iron wares. Pop. (1851) 6088. In 1814 a treaty was concluded here by the allies against Napoleon.

CHAUNY, a town of France, department of Aisne, arrondissement and 20 miles W.N.W. of Laon, situated partly on the right bank of, and partly on an island in the Oise, at the commencement of the canal of St Quentin. It has some trade in cider, linen cloths, and hosiery, and is a depôt for coals from Flanders and glass mirrors from St Gobain. Pop. 5200.

CHAUVIN, Stephen, a celebrated minister of the Reformed religion, born at Nismes, who retired to Rotterdam at the revocation of the edict of Nantes, where he began a new *Journal des Sçavans*. He was afterwards made professor of philosophy at Berlin, and discharged that office with much honour and reputation. His principal work is a *Lexicon Philosophicum*, which he published at Rotterdam in 1692. A new and enlarged edition was printed at Lewarden in 1703. Chauvin died in 1725.

CHAUX-de-Fond, La, a town of Switzerland, canton and 10 miles N.W. of Neufchâtel, in the rugged and narrow valley of the Jura, 3100 feet above the level of the sea. It is celebrated for the manufacture of gold and silver watches, which employs about 500 of its inhabitants. Pop. 8500.

CHAVES, a fortified town of Portugal, province of Tras-os-Montes, on a plain near the right bank of the Tamega, which is here crossed by a fine old Roman bridge of eighteen arches. It has hot saline springs. Pop. about 6000.

CHAZELLES, Jean Mathieu de, a French mathematician and engineer, was born at Lyons in 1657. He was employed for some time by M. Cassini in measuring the meridian, and afterwards taught mathematics to the Duke of Mortemar, who procured him the preferment of hydrographic professor for the galleys of Marseilles. In 1686 Chazelles went on board the galleys in their campaigns, and kept his school at sea. He was sent to the west coasts in July 1689 to examine the practicability of so contriving galleys that they might live upon the ocean, and be employed to tug the men-of-war when becalmed; and having set sail with fifteen galleys from Rochefort, cruised as far as Torbay, in England, and proved serviceable at the descent upon Tynemouth. On his return he published his observations, and drew maps of the coasts he had visited, with a description of all the harbours, &c. discovered. These maps were inserted in the *Neptune Français*, published in 1692, in which year Chazelles acted as engineer at the descent on Oneille. In 1693, Monsieur de Pontchartrain, secretary of state for the marine, engaged Chazelles to publish a second volume of the *Neptune Français*, which was to include the hydrography of the Mediterranean. For this purpose he passed through Greece, Egypt, and other parts of Turkey. When in Egypt he measured the pyramids; and finding that the angles formed by the sides of the largest were in the direction of the four cardinal points, he concluded that this position must have been intended, and also that the poles of the earth and meridians had not deviated since the erection of these colossal structures. Chazelles likewise made a report of his voyage in the Levant, and concerning the position of Alexandria. He was made a member of the academy in 1695, and died in 1710.

CHEADLE, an ancient and irregularly-built market-town of Staffordshire, 14 miles N.N.E. from Stafford. Chief manufactures—copper, brass, tin, cotton, and tape; besides some trade in coal. It contains seven places of worship (including a fine Roman Catholic chapel, built chiefly by the Earl of Shrewsbury), and four principal schools. Pop. (1851) 2728.

CHECKY, or Chequy, in *Heraldry*, is used of a shield or bordure divided into chequers or squares, in the manner of a chess-board, which is supposed to represent a field of battle.

CHEDUBA, an island in the bay of Bengal, situate 10 miles from the coast of Arracan, between Long. 18. 40., 18. 56.; Lat. 93. 31., 93. 50. It extends about 20 miles in length from north to south, and 17 miles from east to west, and has an area of 250 square miles. The channel between the island and the mainland is navigable for boats, but not for large vessels. The geology of Cheduba affords various indications of a volcanic nature. Along the coast are earthy cones covered with a greensward, from which issue springs of muddy water emitting bubbles of gas. Among the mineral productions, copper, iron, and silver ore have been discovered. The island is also noted for its petroleum wells, the oil derived from which is of excellent quality: it possesses a strong pungent smell, and is extensively used in the composition of paint, as it possesses the property of preserving wood from the ravages of insects, especially the white ant. Timber is not abundant. The gamboge tree, prized for the valuable properties of its gum, is found of a good size; as is also the wood-oil tree. Tobacco, cotton, sugar-cane, hemp, and indigo are among the productions of Cheduba; but the staple article is rice, which is of superior quality, and the chief article of export. The inhabitants are of the Mugh persuasion. Cheduba fell to the Burmese in the latter part of the last century. From them it was captured in 1824 by the British, to whom it was confirmed in 1826 by the treaty concluded with the Burmese at Yandaboo.

CHEESE (Saxon, *cese*, or *cyse;* Lat. *caseus*), the curd of milk, coagulated by rennet or some acid, separated from the whey, and pressed. See Dairy. The quantity of cheese imported in the year ending 1853 into the United Kingdom from Europe was 278,179 cwts., and from the United States 11,275 cwts.; while during the same period the exports amounted to 5694 cwts.

CHEKE, Sir John, a celebrated statesman, philologer, and divine, descended of an ancient family in the Isle of Wight, was born at Cambridge in 1514, and educated at St John's College. After taking his degrees in arts, he was first chosen Greek lecturer; and then, in 1540, professor of that language, with a salary of L.40 a-year. In this station he was principally instrumental in reforming the pronunciation of the Greek language, which had been much neglected, and was imperfectly understood. About 1544 he went to court, and was appointed Latin tutor to Prince Edward. About this time he was made canon of the college newly founded at Oxford, so that he must then have been in orders. On the accession of his royal pupil to the crown, Mr Cheke was first rewarded with a pension of a hundred merks, and afterwards obtained several considerable grants from the crown. In 1550 he was made chief gentleman of the privy chamber, and was knighted the following year; in 1552, chamberlain of the exchequer for life; in 1553, clerk of the council; and soon afterwards secretary of state and privy-counsellor. But these honours were of short duration. Having concurred in the measures of the Duke of Northumberland for settling the crown on the unfortunate Lady Jane Grey, and acted as her secretary during the nine days of her reign, on the accession of Queen Mary he was sent to the Tower, and stripped of the greater part of his possessions. In September 1554 he obtained his

liberty, and a license to travel abroad. He went first to Basle, thence to Italy, and afterwards returned to Strasburg, where he was reduced to the necessity of reading Greek lectures for subsistence. In 1556 he set out to meet his wife at Brussels; but before he reached that city he was seized by order of Philip II., thrown into a waggon, and thus ignominiously conducted to a ship, which brought him to the Tower of London. He soon found that religion was the cause of his imprisonment; for he was immediately visited by two Catholic priests, who endeavoured to convert him, but without success. He was at last visited by Fleckenham, who told him from the queen that he must either comply or be burned. This powerful argument had the desired effect; Sir John Cheke formally complied, and his lands, upon certain conditions, were restored; but his remorse soon put an end to his life. He died in September 1557, at the house of his friend Mr Peter Osborne, in Wood Street, London, and was buried in St Alban's church. He left three sons, the eldest of whom, Henry, was knighted by Queen Elizabeth.

He wrote, 1. *A Latin translation of two of St Chrysostom's homilies*, Lond. 1543, 4to; 2 *A Latin translation of six homilies of the same Father*, Lond. 1547; 3. *The Hurt of Sedition*, Lond. 1549, 1576, 1641; 4. *A Latin translation of the English Communion Service*, printed among Bucer's *Opuscula*; 5. *De Obitu doctissimi et sanctissimi theologi Domini Martini Buceri*, &c., Lond. 1551; 6. *Carmen Heroicum, in Antonium Deneium*, Lond. 4to; 7. *De Pronunciatione Græcæ Linguæ*, Basle, 1555, 8vo; 8. *De Superstitione*; 9. *Several Letters* published in his life by Strype; 10 *A Latin translation of Archbishop Cranmer's book on the Lord's Supper*, 1553; 11. *Translation of Leo de Apparatu Bellico*, Basle, 1554. He left also a great many unpublished writings, which are most probably lost.

CHEIROTHERIUM. In the sandstone of Hildburghausen in Saxony, and in the second-sandstone of Stourton in Cheshire, are foot-prints of an extinct animal, to which Kauss assigned this name. The prints are large, and strongly resemble the human hand in form. Kauss supposes that they belong to a mammifer, while others with less probability refer them to some reptile. The animal appears to have frequented a muddy shore; for ripple-marks and rain-drops occur on the Cheshire sandstone, along with the foot-prints of the Cheirotherium.

CHE-KIANG, a maritime province of China, between N. Lat. 27. and 31., and E. Long. 118. and 121; bounded on the N. by Kiang-see; E. by the Eastern Sea; S. by Fokien, and W. by Kiangsi and Nganhwui. Area 39,150 square miles; population, according to the last official census of 1825, 26,256,784. This is one of the most fertile and most commercial of the provinces of China. It is well watered, and produces abundance of cotton, silk, tea, rice, and other grains. Its manufactures include silk, cotton, and linen goods, gold and silver stuffs, paper, &c. The capital is Hangchau-Fu.

CHELIDONIAS, another name for Favonius, the spring wind, so called because it brings the swallows. (Pliny.)

CHELMSFORD, the county-town of Essex, 29 miles N.N.E. from London; situated in a valley on the Chelmer, near its confluence with the Cann. The Cann is crossed by two bridges, one of stone and the other of cast-iron, and there are also two bridges over the Chelmer, which divides into two branches and incloses an island called Mesopotamia, famous to the townspeople as the scene of mock-elections. The parish church of St Mary is an ancient Gothic edifice, and has been twice rebuilt. Besides it there are six churches belonging to different religious bodies. It has a grammar-school founded by Edward VI., national, Lancasterian, and infant schools, a mechanics' institute, museum, library, &c. It is the seat of the county assizes and quarter-sessions, and has an elegant shire hall. Most of the inhabitants are engaged in agriculture, and the trades connected with it. Chelmsford communicates with Maldon by means of a canal, and with London by the Eastern Counties railway. Pop. 6033.

CHELSEA, a town of Middlesex, on the Thames, in the hundred of Ossulston; which, by the rapid extension of London towards the west, has now become one of the suburbs of the metropolis. In the seventeenth and eighteenth centuries it was much frequented by pleasure parties from the city, and was a favourite retreat of the nobility and gentry, many of whom had residences in the village and its environs. It has now altogether lost its rural character, and since the beginning of the present century has been rapidly extending in all directions. The most interesting feature of the town is the Royal Hospital for invalid soldiers; the plans and design of which were furnished by Sir Christopher Wren, and the foundation-stone laid by Charles II. with great ceremony in 1682. The building—which is of brick, with stone quoins, pillars, and cornices—was completed in 1690, at an expense of about L.150,000. It consists of three quadrangles, one of which is open on the side looking towards the river. The hospital affords accommodation to upwards of 500 invalid soldiers, who in addition to their food and clothing receive pensions varying according to the rank and service of the recipients from 8d. to 3s. 6d. a-day. The out-door pensioners are about 70,000 in number, and receive pensions varying from 4d. to 2s. 6d a-day. The establishment is managed by a governor, lieutenant-governor, and subordinate officers. Besides the hospital, Chelsea possesses a Royal Military Asylum (founded by the Duke of York in 1801, and completed in 1805) for the education of the children of soldiers and non-commissioned officers. In this establishment nearly 1000 children receive an excellent education on Bell's plan. Immediately adjoining the hospital are the botanical gardens of the London Apothecaries' Company, granted by Sir Hans Sloane, and occupying four acres of ground. A statue of the donor, by Rysbrach, is to be seen in the centre of the gardens. There is a considerable number of churches in Chelsea, the most noteworthy of which are the old parish church, containing some interesting monuments; Christ's church, St Jude's, Upper Chelsea church, and St Saviour's. Besides these, there are many Methodist, Independent, Presbyterian, and Catholic chapels. There are four National, two British and Foreign, and many Sunday and infant schools. St Mark's Training College for schoolmasters is attended by about 75 students. There is a similar institution for schoolmistresses, attended by a still larger number of pupils. Pop. of district (1851) 56,538.

CHELTENHAM, a parliamentary borough in a valley watered by the Chelt, and sheltered by the Cotswold Hills, Gloucestershire, 88 miles N.W. from London. Although an ancient town and existing under the Romans it was a place of no importance till the discovery of its saline springs, containing muriate of soda, sulphate of soda, and sulphate of magnesia, in the beginning of the eighteenth century. From its comparatively modern origin, the streets and buildings of Cheltenham are spacious and elegant, and its promenades are reckoned among the finest in England. St Mary's church is a cruciform edifice with a lofty octagonal spire, and contains a curious font and ancient stone cross. Trinity church and Christ church are modern, and are much admired. Besides these there are several other established and numerous Dissenting churches. It contains a proprietary college (capable of containing 300), a Church of England training college, and numerous schools and charities. Cheltenham contains no manufacturing establishments of any importance. It is the seat of a county court, and returns one member to the imperial parliament. Pop. (1851) 35,051.

CHEMISE, in *Fortification*, the wall with which a bastion or any other bulwark of earth is lined, for its greater support and strength.

CHEMISTRY.

CHEMISTRY, as a regular branch of natural science, is of comparatively recent origin, and can hardly be said to date from an earlier period than the latter third of the past century. It is true that, before that time, many men of high talent and wonderful ingenuity had devoted themselves to chemical studies; and the very name of the science, which, with the prefixed article, forms the well-known word Alchemy, is of Arabian origin. The early Greek philosophers had some vague yet profound ideas on the subject, but their acquaintance with it was limited chiefly to speculation *a priori*, founded on a general and often inaccurate observation of natural phenomena. Yet their acuteness was such, that some of their speculations as to the constitution of matter coincide in a most wonderful manner, as will be hereafter shown, with those which are now beginning to prevail among the most profound modern philosophers.

In these early ages, and long afterwards, those who turned their attention to the experimental part of the subject, which the Greeks hardly attempted, did so with some other object in view than the mere cultivation of chemistry as a science for its own sake. They either laboured to discover and produce new remedies, and in this manner were led to the search after the panacea or universal remedy, the elixir vitæ, and similar desiderata, which indeed formed the chief occupation of alchemists, as chemists were then called, for many centuries; and these transcendental researches, while they failed in their professed objects, yet led to the discovery of many of the best known and most important compounds of chemistry, as well as of many most valuable medicines. Or else, on the other hand, led by speculations as to the nature of the material elements, which are much less absurd, or at least were then much less absurd, than we are apt to suppose, they attempted to effect the transmutation of one element into another, and especially of the baser metals into gold and silver. In this way arose the search after the philosopher's stone, supposed to be capable of effecting this transmutation, and after the universal menstruum or solvent, which was expected to have similar effects, or at least to facilitate the necessary processes. In this pursuit, as in the other, the alchemists failed; but their indefatigable industry and their wonderful ingenuity led them to numerous discoveries neglected at the time in many instances, but which have had a most marked and important influence on the development of the modern science.

It has already been said, that the alchemists did not study chemistry as a science, but only practised it as a means of attaining their objects. They proceeded on certain speculative notions, adopted *a priori*, and supposed to be established truths. But at last the time came, when the materials they had collected with so much industry and zeal were made the foundation, on the Baconian or inductive system, of a new science. This could not take place until after the development of physics, or mechanical philosophy, which treats of those properties which are common to all material substances, and which development immediately followed or accompanied that of astronomy.

From the very nature of chemistry, it was impossible that it should take a truly scientific form, until the balance was applied to it. Up to that time, speculations *a priori*, and erroneous interpretations of observed phenomena, retarded its progress, although new and important discoveries were daily made. But Lavoisier, who first employed the balance in the study of some of the most important phenomena, such as those of combustion, on a certain theory of which the then existing science was founded, effected a complete revolution in chemistry; and from that time, 1760–1770, the science of chemistry has made rapid and continuous progress.

Our limited space will not permit us to enter more minutely into the history of chemistry, and we shall therefore at once proceed to give some account of the science as it now stands.

It is not easy, and fortunately it is not necessary, to define chemistry in a few words. We may describe it as the science which treats of the properties of the different kinds of matter, or elementary bodies, which exist in our universe, the laws which regulate their mutual actions, and the proportions in which they combine together to form the compounds which, for the most part, constitute the animal, vegetable, and mineral kingdoms, as well as the properties of these compounds. But it is necessary here to explain the term elementary body or element.

ELEMENTARY BODIES.

The ancients, as is well known, admitted four elements, earth, water, air, and fire, of which all things were composed. But it is a mistake to suppose that they used the term element in the same sense as we do. That which they understood by it was rather the forms under which matter is presented to us, than the nature or essence of material substances. Thus, by earth they understood solid matter; by water, liquid matter; and by air, matter in the state of gas or vapour. Fire was their name for what we call heat or caloric, which causes solid bodies to become liquid, liquids to become gaseous. And in this sense the four elements of the ancients do indeed include all material substances.

The meaning now attached to the word element is very different from this. We observe that there are different kinds of matter, whether solid, liquid, or gaseous; and on investigation we find that some of these may be resolved into two or more different substances, some of which again may in like manner be resolved into others, but at last we come to substances in which we are unable, with all our appliances, to detect more than one kind of substance or matter. Some such substances occur in nature, although most natural substances contain more than one kind of matter. To take a few examples. Common salt can easily be shown to consist of two different kinds of matter; of a metal, sodium, and of a non-metallic body, chlorine. Water can be resolved into two gaseous non-metallic substances, oxygen and hydrogen. Cinnabar consists of mercury and sulphur; marble of three bodies, the metal calcium, the non-metallic body carbon, and oxygen. But it is out of our power, by any means yet known to us, to detect any other substance in sodium, chlorine, oxygen, hydrogen, mercury, sulphur, calcium, and carbon; sodium yields only sodium, sulphur only sulphur, and so on. And when this is the case—when a body cannot be proved to contain more than one kind of matter—it is called an element or elementary body, because such bodies are, in fact, the elements of which the material world around us is made up. Some elementary bodies are found in nature as such—for example, mercury, sulphur, carbon, gold, silver, iron, copper, and a few others; but in general two or more are found united, as in air, water, rocks, earths, plants, and animals.

It must be observed, that when we call a substance, such as carbon or chlorine, elementary or simple, we do not assert that it is absolutely and certainly simple, or may not be found hereafter to contain more than one kind of matter; we only mean that, to us, or so far as our knowledge extends, it is so. Thus, at the beginning of the present century potash and soda were considered elementary, be-

cause no one could prove them to be compounded; yet soon afterwards, by the aid of a new power, that of galvanism, Davy succeeded in showing that they contained each a metal, potassium and sodium, united to oxygen. It may happen that some future chemist should find the means of proving that these metals themselves contain more than one kind of matter, in which case they would no longer be called elementary. Nay, it is even considered probable, that all the metals may ultimately prove to be compounds, not elements; and the same opinion is entertained regarding such elements as chlorine, bromine, and iodine. But so long as this is not demonstrated, these bodies, and all others in the same position, must be retained on the list of elements.

The researches of chemists have, up to this time, detected about 60 elementary substances; of which 12 are non-metallic, and the rest all metals. The non-metallic bodies are also called *metalloids.*

Of these elements, the whole of our earth, including the waters and the atmosphere belonging to it, and likewise all the living organisms, whether animal or vegetable, are made up. But it is only a small number of the elements which occur in any great abundance; for the majority, especially of the metals, are only found in a few rare and scattered minerals.

The following table exhibits the elements arranged alphabetically. The second column contains the symbols or abbreviations used to represent them in chemical notation, and the third contains the numbers which represent their respective combining proportions, as ascertained by experiment, that of hydrogen being made the standard of comparison = 1. The meaning and value of these numbers will be presently explained.

Elements.	Symbols.	Hydrogen = 1
ALUMINUM	Al	13 7
Antimony (Stibium)	Sb	129
Arsenic	As	75
Barium	Ba	68 5
Bismuth	Bi	71
Boron	B	10·9
Bromine	Br	80
Cadmium	Cd	56
CALCIUM	Ca	20
CARBON	C	6
Cerium	Ce	47
CHLORINE	Cl	35·5
Chromium	Cr	26 7
Cobalt	Co	29 5
Columbium (Tantalum)	Ta	92
COPPER (Cuprum)	Cu	31·7
Didymium	D	49 6 ?
Erbium	E	?
Fluorine	F	18 9
Glucinium	G	26 5
Gold (Aurum)	Au	99 6
HYDROGEN	H	1
Iodine	I	127·1
Iridium	Ir	99
IRON (Ferrum)	Fe	28
Lanthanium	La	47 ?
LEAD (Plumbum)	Pb	103·7
Lithium	Li	6·5
Magnesium	Mg	12·2
Manganese	Mn	27·6
Mercury (Hydrargyrum)	Hg	200
Molybdenum	Mo	46
Nickel	Ni	29·6
Niobium	Nb	?
NITROGEN	N	14
Norium	No	?
Osmium	Os	99·6
OXYGEN	O	8
Palladium	Pd	53 3
Pelopium	Pe	?
PHOSPHORUS	P	32
Platinum	Pt	98 7
POTASSIUM (Kalium)	K	39·2
Rhodium	R	52·2
Ruthenium	Ru	52·2
Selenium	Se	39·5
Silicon	Si	21 3
Silver (Argentum)	Ag	108
SODIUM (Natrium)	Na	23
Strontium	Sr	43 8
SULPHUR	S	16
Tellurium	Te	64 2
Terbium	Tb	?
Thorium	Th	59 6
Tin (Stannum)	Sn	59
Titanium	Ti	25
Tungsten (Wolfram)	W	95
Uranium	U	217·2
Vanadium	V	68 6
Yttrium	Y	32 2 ?
Zinc	Zn	32 6
Zirconium	Zr	22 4 ?

Those elements, the names of which are printed in small capitals, are the most abundant and the most important; for of them, practically, the mass of the globe and all its inhabitants, the sea and the air, are composed.

Thus, the air consists for the most part of only two elements, oxygen and nitrogen; water of two, oxygen and hydrogen; sea salt of two, sodium and chlorine; calcareous matter, such as marble, limestone, chalk, and Iceland spar, as well as the earthy part of shells, of three elements, carbon, calcium, and oxygen. Silica, quartz, or sandstone, contains silicon and oxygen; gypsum consists of sulphur, calcium, and oxygen; bone earth of phosphorus, calcium, and oxygen; woody fibre of carbon, hydrogen, and oxygen; muscular fibre of carbon, hydrogen, nitrogen, sulphur, and oxygen; pure clay of aluminum and oxygen; iron ore of iron and oxygen, or of carbon, iron, and oxygen; lead ore of lead and sulphur; copper ore of copper and sulphur. The ashes of land plants contain much carbonate of potash, that is carbon, potassium, and oxygen; those of sea plants, carbonate of soda, or carbon, sodium, and oxygen. Many, indeed most, rocks and soils are more complex, being mixtures of several of the substances just enumerated. Thus, granite, gneiss, and mica slate, all contain quartz, felspar, and mica; and the two latter minerals are compounds of silica with clay or alumina, potash, lime, &c. Clay slate grauwacke, and other rocks, consist chiefly of felspar; and the beds of coal contain much carbon, with less hydrogen nitrogen, and oxygen, than the vegetables from which they are derived. Soils are rocks, more or less disintegrated; but contain the same substances, namely, quartz or silica, clay or alumina, limestone, felspar, gypsum, &c., which are found in the rocks which yield them, generally mixed with decaying vegetable matter or mould.

The preceding statements will show how small is the number of the more important elements; that is, of those which constitute an important part of the earth's crust. And even among the substances named there are one or two, such as the ores of lead and copper, which occur only in veins and in comparatively small quantity. But these metals, and a good many others, such as gold, silver, mercury, zinc, antimony, chromium, arsenic, cobalt, nickel, platinum, magnesium, &c., although, in comparison with the more abundant elements their quantity is small, yet occur in sufficient abundance to be applied to innumerable useful purposes. Iron, although its ores are scarce, compared with the common rocks, is yet, in small proportion, so universally diffused that it may be reckoned among those elements which make up the chief part of the earth's crust.

It will be seen that of all the elements oxygen is the most universally present, forming a constituent part, indeed, of all rocks and soils, excepting only rock salt, which is hardly to be called a true rock; of all plants and animals, of water, and of the air. It cannot, therefore, be doubted that oxygen is of all the elements the most important.

Next to it, in the mineral kingdom, come silicon, aluminum, calcium, carbon (in limestone), sodium, chlorine

(these two in salt), hydrogen (in water), nitrogen (in air), magnesium, iron, potassium, and sulphur, and in smaller proportion, phosphorus, iodine, bromine, and fluorine, besides the ores of metals.

But in the animal and vegetable kingdoms, while nearly the same elements form their mass, the proportions vary much. Carbon is the predominant and characteristic element of all organized structures; after it come hydrogen, nitrogen, oxygen, phosphorus, and calcium (in bones), sulphur, potassium, chlorine, sodium, and in smaller proportion iodine and fluorine. Aluminum hardly occurs in the organized world.

It is thus obvious, that there is no essential distinction, so far as concerns the mere nature of the elements, between the mineral and the organized kingdoms of nature. The principal elements of both are the same; and the difference lies, first, in the predominance of oxygen in the former, and of carbon in the latter; and, secondly, in the more complex nature, as we shall hereafter see, of the chief compounds which enter into the formation of organized tissues.

It is hardly necessary to point out, that by the very definition we have given of the term element, it is implied that we cannot transmute one element into another. We do not mean to assert that it is absolutely or physically impossible to transmute one of our so-called elements into another, but only that we cannot do this up to the present time. And there is every reason to believe that if we should ever succeed in transmuting one of our elements into another, it would be in consequence of our discovering, which is quite conceivable, that one or both of the transmutable bodies was in reality a compound, and not a true element. There are certain groups which have so many characters in common to all the members of them, that the simplest explanation would seem to be, that all these members contain one common ingredient or element, to which the common properties are to be ascribed, and which, in each case, is combined with a different element, to which the differences are due.

Thus all the metals agree in having the metallic lustre, and in conducting heat and electricity, besides having a general resemblance in their chemical characters; and it is conjectured that all metals contain one common ingredient. But if this be so, the metals cease to be simple elementary bodies, and must be compound. Again, there is a wonderful and accurately graduated analogy between chlorine, bromine, and iodine, in all their characters; and the opinion is pretty generally held, that they also will ultimately prove to be compound bodies, and to possess a common ingredient. But this, in the meantime, is but conjecture.

When we shall have explained the views now held as to the atomic constitution of matter, we shall mention another conjecture as to the possibility of the transmutation of bodies truly elementary. For the present it may suffice to point out that if such transmutation be supposed possible, it must be under circumstances very different from those which commonly exist. For if it were possible, under existing circumstances, that one element should become converted into another, the whole foundation, not only of chemistry, but of nature, would be destroyed. If, for example, carbon, the predominating and essential element of organized beings, could, under ordinary circumstances, be converted, as has been alleged, into silicon, one of the chief elements of mineral nature, how could plants or animals, to which carbon, as such, is essential, possess any stability? As soon as the carbon of any vegetable or animal tissue became silicon, that tissue must cease to exist. Again, if such transformation were possible, under the usual conditions of experiment, chemical analysis would be utterly impracticable, since it would be impossible to determine with accuracy the amount or weight of an element, liable at any time to become a different one. It is easy to see that an indispensable condition of the very existence of the material world we inhabit is the *stability* of the elements of which it is made up. An unstable element is almost a contradiction in terms; and, therefore, practically, the transmutation of elements, under the usual conditions of experiment, must be regarded as necessarily unattainable, although it may be conceivable under widely different circumstances. And when we speak of the indispensable stability of elementary bodies, it is altogether independently of the question whether these be really elementary, or, as is perhaps more probable in many cases, compounds which we are unable to decompose, or prove to be compounds. Thus, whether carbon be really elementary or not, it must be a stable element *to us*, otherwise the compounds it forms could have no stability.

Having explained what is understood by elements or elementary bodies, we shall next proceed, before describing the elements individually, to mention briefly the important laws which regulate chemical action between different elements, and especially those which have reference to the proportions, by weight as well as by volume, in which they combine together. It will also be necessary to explain the atomic hypothesis, which is adopted to furnish an explanation of the facts alluded to.

CHEMICAL COMBINATION.

Chemical combination, or chemical action, is to be distinguished from such actions of matter on matter as are physical or mechanical. Thus, all bodies are acted on by the force of gravitation, and, as we say, *attracted* towards the earth, and towards each other. A rod of sealing wax briskly rubbed on cloth or silk attracts light bodies; a magnet attracts iron filings. In all these cases, one mass or portion of matter acts on or attracts another, and motion is the result. These actions, or attractions, of gravitation, electricity, and magnetism are exerted between different portions of matter, but not necessarily between different *kinds* of matter; and they are also exerted at sensible distances, which in the case of gravity or of magnetism may be very great distances.

In all these respects chemical action is different. It is exerted invariably between different kinds of matter. It operates at insensible distances, and the result is, not sensible motion, but the formation of one or more new substances, by the combination of those which act on each other. The evidence of this is found in changes of properties, both physical and chemical. Of course the simplest case is that in which two elements act on each other, or combine to form a new body, which is said to be a compound of the two. Two portions of sulphur or two of iron cannot act chemically on each other, but can only exhibit mechanical attractions, such as those of gravitation, cohesion, and the like. But if a portion of sulphur and a portion of iron be placed in contact, at a certain temperature, chemical action ensues; the sulphur and iron combine together, and a new substance is the result. This new substance contains these two elements, and is called the sulphuret of iron. It is neither yellow and easily fusible like sulphur, nor metallic, malleable, and tenacious, like iron. It is of a brassy colour, with some degree of metallic lustre, and very brittle. Here the new body or compound formed has properties quite distinct from those of its elements. Now this is universally the case where chemical combination takes place. The change of properties is usually complete. Thus oxygen and hydrogen, two permanent gases, combine and produce water, a liquid at ordinary temperature. Iodine, which is a black solid, forms with mercury, which is white and metallic as well as liquid, a fine scarlet crystalline compound; and with lead, a compound which forms hexagonal plates of the colour and lustre of gold. Sulphur with mercury forms vermilion. Nitrogen and hydrogen, two inodorous and taste-

less gases, combine to form the caustic and pungent ammonia. The same law holds in regard to compound bodies, which act on each other. Thus sulphuric acid, which is highly corrosive, and caustic potash, a substance used as an escharotic, unite to form sulphate of potash, a mild neutral salt; and there are hundreds of similar cases.

In every case of a chemical compound, we can show that it contains two or more elements, and we thus distinguish compound bodies from such as are simple or elementary.

In every case of chemical action between two substances, whether simple or compound, combination takes place. But in a great many instances decomposition also occurs; that is, substances previously combined are separated. In the greater number of cases both these changes happen; some of the substances present enter into combination, while others are separated; or the same substance separates from that with which it had been united, and combines with another. Hence the almost infinite variety of the results which the chemist can produce.

When zinc is introduced into a solution of chloride of tin, a compound of tin and chlorine, the zinc combines with the chlorine, forming chloride of zinc, and the tin is separated in bright metallic crystals. Here we have both combination and decomposition. When iodide of potassium is added to chloride of mercury, what is called double decomposition, which, however, implies double combination, takes place. The potassium leaves the iodine to unite with the chlorine, while the mercury leaves the chlorine to unite with the iodine, and thus, while the two original compounds are destroyed, two new ones, the chloride of potassium and the iodide of mercury, are formed.

There are certain conditions which favour and promote, others which impede or oppose, chemical action. Thus, two substances, both solid, rarely act on each other, because the force of cohesion among the particles of each prevents them from coming into sufficiently close proximity to those of the other. In some few instances, as when iodine and phosphorus act on each other, their mutual attraction overcomes the obstacle offered by cohesion.

In general, the best plan is to liquefy one of the substances, or both, either by the aid of heat, or by the use of some solvent, such as water. If this be done, and if the attraction or tendency to combine be powerful, combination will generally follow.

The liquid form is the most favourable to chemical action, because it permits the particles to come into close proximity. Hence most substances are employed in a state of solution.

The gaseous form is unfavourable to chemical action, because the particles of elastic fluids or gases are at a great distance from each other compared to that which separates them in the liquid state. Yet, where the attraction is powerful, gases do act on each other. Thus oxygen and deutoxide of nitrogen gases instantly combine. But in general gases do not act on each other, unless under the influence of the sun's rays, or of a high temperature. Chlorine and hydrogen do not unite in the dark, but combine with explosion if placed in the sunshine, or if a flame be applied to the mixture. Oxygen and hydrogen do not combine till either a flame is applied or an electric spark passed through the mixture; in both cases they combine with explosion.

Chemical action frequently takes place between a solid and a gas, as when potassium absorbs oxygen; or between a liquid and a gas, as when water absorbs ammonia.

Heat favours chemical action, although at the same time, by increasing elasticity, it tends to separate bodies already combined. But it appears to exalt the energy of chemical attraction in a still higher degree. Hence heat is constantly employed by the chemist, both to liquefy solid bodies, and thus indirectly assist chemical action, and to increase directly the force of chemical attraction.

When several substances are present in a solution, various circumstances contribute to determine the result. If two of the substances present can form a compound which is very insoluble in the menstruum employed, that is, in which the force of cohesion is very great, that substance will be formed, and this will decide the other changes. Thus, when sulphate of soda is mixed with nitrate of baryta, since sulphuric acid and baryta form a compound absolutely insoluble in water, they combine, and the sulphate of baryta being thus formed, the nitric acid must combine with the soda and form nitrate of soda.

In like manner, if any of the substances present have a great tendency to assume the form of gas, that is, if its elasticity be great, it will escape as gas, and thus determine the result. If carbonate of lime be mixed with nitric acid, the carbonic acid, which has a far greater elasticity than nitric acid, escapes as gas, and the lime of course combines with the nitric acid. It is often said that carbonic acid is a weak acid, and is expelled by a stronger, such as nitric acid; but it is the elasticity of carbonic acid which causes it to appear weak.

At ordinary temperatures, sulphuric acid expels silicic acid from its combinations. But at a red heat, silicic acid expels sulphuric acid, because at that high temperature the elasticity of sulphuric acid is very great.

When a number of different substances are present in a solution, and when these are capable of combining two and two,—as, for example, several acids with several bases, each acid being capable of combining with each base,—the result is determined by all the above circumstances; by the temperature; by the relation of the solvent to the compounds that may be formed; by the force of cohesion in these possible compounds, and by the force of elasticity in such of the bodies present as tend to assume the elastic form.

It was formerly the custom to give tables of affinity or of decomposition, showing the supposed comparative force of chemical attraction between two or more acids, for example, and any given base; or between two or more bases and a given acid. That body which expelled another and took its place was called the stronger, and was said to exert a more powerful affinity, or chemical attraction, than the substance it expelled for the third body. Thus, sulphuric acid, which expels nitric acid from nitrate of potash, was said to have a stronger affinity for potash than nitric acid. But in this case, the change, which only takes place fully with the aid of heat, is determined by the tendency of the nitric acid to assume the gaseous form, that is, by its elasticity; and it affords no proof that nitric acid is weaker than sulphuric. Nay, as we have seen, an acid, apparently very feeble at ordinary temperatures, may become, at a red heat, capable of expelling sulphuric acid, by which it is itself expelled in the cold. In consequence of these and similar considerations, tables of affinity are no longer used, since they convey no information but the bare fact, that at a given temperature, and under certain circumstances, certain changes occur, and cannot tell us the real comparative force of affinity or attraction between any two or more substances of the same class, and a third with which both can unite.

When one body leaves another with which it had been combined to unite with a third, the result used to be called an example of elective affinity; as if the body B, in the compound AB, chose or preferred the body C, and thus formed the compound BC, A being set free. But it is now considered, that when a body C is placed in contact with a compound AB, the compound BC is only formed when it has a greater cohesive force than AB; or when A has a greater elasticity or cohesion than C, or when both causes are combined. And we have no means of ascertaining whether the attraction between B and C be greater than that between A and B, considered apart from the influencing circumstances.

There is another case, namely, where two bodies refuse

to act on each other till a third is added, which tends to combine with the new compound that may be formed. Thus, zinc does not decompose water till sulphuric acid be added, and then hydrogen is set free, while the oxygen of the decomposed water is found to be combined with zinc and sulphuric acid, forming sulphate of oxide of zinc. This was formerly called a case of predisposing affinity, and the acid was said to promote the action in virtue of its attraction for the oxide of zinc about to be formed. It is obvious, however, that it is absurd to speak of the attraction of sulphuric acid for a body not yet in existence, and still more so to ascribe to this attraction the formation of that body. The truth is, that when zinc is in contact with water, no change occurs; the forces tending to preserve the existing state of things being superior to those which tend to disturb it. But when the acid is added, an additional disturbing force is brought into play, the existing arrangement is overturned, and the zinc, oxygen, and sulphuric acid unite to form the sulphate of oxide of zinc, while the hydrogen, from its elasticity, is disengaged as gas.

There are, besides, some remarkable instances, in which certain substances appear, by their mere presence, to promote chemical action without taking a share in the change, as the sulphuric acid does in the case last mentioned. Thus, oxygen and hydrogen, which, when mixed, may be kept for any length of time without combining, rapidly combine if allowed to come in contact with platinum, whether in a compact, dense, polished plate, in a porous spongy form, or in the form of powder. And yet the platinum does not in any way enter into the change, but remains, as before, uncombined. It must be admitted that we cannot satisfactorily explain this striking fact. The proposed explanations will be mentioned under Hydrogen.

In like manner, yeast or ferment induces the fermentation or decomposition of sugar, if placed in contact with it, yet neither gives anything material to the sugar, nor receives anything from it. It is supposed to act by the communication of a mechanical impulse or motion to the particles of the sugar, which motion or impulse destroys the existing equilibrium, and a new equilibrium is established, which is permanent under the existing circumstances.

Some have included these two last-named modes of action under one head, under the name of catalysis or catalytic action. But independently of the circumstance that this is merely giving a name to the phenomenon which we cannot explain, and not explaining it, it would seem that we can hardly conceive that the same cause which produces the *combination* of oxygen and hydrogen by mere contact, should also by mere contact cause the *decomposition* of sugar, or the separation of bodies already combined.

Such is a brief account of the circumstances which promote or oppose chemical action. Let us now consider the subject in reference to the quantity of the substances which combine, and we shall find it to be a matter of the highest importance; the study of which, in fact, has created the existing science of chemistry.

COMBINATION IN DEFINITE PROPORTIONS.

The researches of chemists have established a most important law; which is, that when two or more substances unite to form a new compound, they do so in definite, fixed, invariable proportions.

Thus, hydrogen and oxygen unite to form water. Now, when 1 grain (ounce, pound, &c.) of hydrogen is thus converted into water, the water produced weighs, invariably, exactly 9 grains (ounces, &c.) Consequently hydrogen and oxygen unite, *to form water*, always in the proportion of 1 part of hydrogen to 8 parts by weight of oxygen. If we analyze (after purifying it) the water of a river, of a lake, of the sea, of rain, or of snow and ice, whether newly formed, or produced ages ago, we shall always find that 9 grains of water contain 1 grain of hydrogen and 8 grains of oxygen. If we mix these elements in any other proportion, such as 1 to 10, or 2 to 8, and cause combination to take place, we shall find, in the former case, 2 parts of oxygen, and in the latter 1 part of hydrogen, remaining uncombined. In short, we cannot form water which shall have a composition different from that just stated. If we should be able, and this is possible, to cause these two elements to combine in any other proportion, the resulting compound, as will be seen hereafter, would be, not water, but a totally different compound; and this compound, in its turn, would be found, whenever formed, to be as invariable in the proportion of its elements as water itself.

If we analyze the oldest marble, geologically speaking, we shall find it to consist of carbon, calcium, and oxygen, in the proportions of 6 parts, by weight, of carbon, 20 of calcium, and 24 of oxygen, which make up 50 parts of carbonate of lime. If we analyze the newest chalk, or if we prepare, artificially, carbonate of lime, and analyze it, the results will be precisely the same. These three elements, *to form this compound*, unite in the above proportions invariably.

This law admits of no exceptions; and it is of the very essence of any compound, and a point on which its properties as well as its existence depend, to contain always the same relative amount of its component elements.

It is easy to see that, unless this were so, chemistry as a science could have no existence, for analysis would be impossible. If the proportion of any of the elements of a compound were variable, it would be impossible to attach any value to such a compound. If, for example, iron ore, lead ore, or silver ore, being pure compounds, contained at one time 50 per cent. of the metal, at another 5 per cent., how could such ores be valued? This, in fact, constitutes the difference between a true compound and a mixture, in which the proportions are never twice the same. But all true compounds, if pure and free from admixture of foreign matter, are uniform in their composition. This is the first great law, in regard to quantities, which regulates chemical combination.

The second law is, that if two bodies are capable of combining in more proportions than one, that is, of producing more compounds than one, then a very simple ratio exists between the quantities of the same element in these compounds, when referred to the same amount of the other element. This ratio is usually that of a multiple by a small whole number.

Thus, hydrogen forms with oxygen two compounds with properties totally dissimilar; namely, water or protoxide of hydrogen, and the deutoxide, binoxide, or peroxide of hydrogen. In water, as we have seen, the proportion is 1 of hydrogen to 8 of oxygen. In the peroxide, the hydrogen being made 1 as before, the oxygen is not 8, but 16, that is, 8 multiplied by 2. Again, lead forms with oxygen two compounds, or oxides, which contain—

	Lead.	Oxygen.
Protoxide of Lead,..................	104 parts	8 parts
Deutoxide of Lead,..................	104 ...	16 ...

In some cases there are three or more compounds of the same elements, but the law holds invariably. Thus, nitrogen forms with oxygen the following five compounds:—

	Nitrogen.	Oxygen.
Protoxide of Nitrogen,..............	14 parts	8 parts
Deutoxide of Nitrogen,..............	14 ...	16 ...
Hyponitrous Acid,....................	14 ...	24 ...
Nitrous Acid,..........................	14 ...	32 ...
Nitric Acid,.............................	14 ...	40 ...

Here the oxygen in the first compound is multiplied successively by 2, 3, 4, and 5. Such cases, however, are rare. There are few instances in which two elements combine in more proportions than two or three.

In the cases just cited, the ratio is the simplest possible;

but there occur ratios somewhat different. Thus iron forms with oxygen several compounds. We find, in the

	Iron.	Oxygen.
Protoxide of Iron,	28 parts	8 parts
Sesquioxide of Iron,	28 ...	12 ...
Ferric Acid,	28 ...	24 ...

Here the ratio in the second compound, if we consider the first as in the ratio of 1 : 1, is that of 1 : 1·5, and in the third, it is 1 : 3. Compounds in which the ratio of 1 : 1·5 is observed are called sesqui-compounds. In some rare cases we find the ratio of 1 : 2·5, and of 1 : 3·5. In all other instances, and these constitute the vast majority, the quantity of the element which varies, the other being supposed stationary, is multiplied by a whole number, such as 2, 3, 4, 5, and very rarely 7.

This law is called the law of multiple proportions, and in reference to it compounds may be arranged in two categories. In the first we have the amount of one element, the other being supposed to be fixed, increasing by the simple multiples 2, 3, 4, &c., so that we have a simple arithmetical series.

In the other, we have the following series of numbers for the quantities of the variable element, or some of them, namely—1, 1·5, 2, 2·5, 3, 3·5.

The next law of combination is, that the numbers representing the weights in which bodies combine together are mutually proportional. That is to say, if a certain weight of A combine with a certain weight of B, and if the same weight of A combine with a certain weight of C, then the numbers which represent the weights of B and of C which combine with the same weight of A, will also represent the weights of B and C which will combine together, if they can combine. Or if not, then the combining weight of either B or C will be a multiple or submultiple of the number referred to.

Thus, 8 parts of oxygen unite with 1 of hydrogen to form water, and 1 part of hydrogen combines with 16 of sulphur to form hydrosulphuric acid. Now, when oxygen and sulphur combine, they do so either in the proportion of 8 parts of the former to 16 of the latter, as in hyposulphurous acid; or in those of 16 of oxygen to 16 of sulphur, as in sulphurous acid; or 24 of oxygen to 16 of sulphur, as in sulphuric acid.

Again, 8 parts of oxygen unite with 40 of potassium, and 40 of potassium unite with 16 of sulphur; the quantity which, or a multiple of it, we have just seen to combine with 8 of oxygen.

Lastly, 1 part of hydrogen, which, as we have seen, unites with 8 of oxygen and 16 of sulphur, unites also with 36 parts of chlorine. And 36 parts of chlorine unite with 8 of oxygen, and also with 40 of potassium, the quantity of that metal which combines with 8 of oxygen and 16 of sulphur. Chlorine, however, combines with oxygen in more proportions than one; and here, as with sulphur, the law of multiples holds, for 36 of chlorine combine with 8, with 24, with 32, with 40, and with 56 of oxygen.

It will now be obvious to the reader, that if we ascertain by experiment the proportions by weight in which all the other elements combine with one, such as oxygen (which can combine with all the others except only fluorine), these numbers will at once tell us in what proportions these other elements which combine with oxygen will combine among themselves. Or, if the numbers thus obtained should in any case be found not to represent the combining proportion of one element with another, it will only be because in that instance one of the elements combines according to a multiple or submultiple of the number representing the weight of it, which combines with 8 of oxygen.

It is precisely in this way that the numbers in the third column of the table, p. 438, have been obtained. They represent the proportions by weight, in which, or in some instances in multiples or submultiples of which, they combine, not only severally with 8 parts of oxygen, but with each other, according to the third law, which declares that these numbers are mutually proportional.

It will be observed that in this table hydrogen is made the standard of combining proportions, its number being = 1. And it is for this reason that oxygen is represented by 8, being, as we have seen, the quantity which in water is combined with 1 of hydrogen. Hydrogen has been chosen in this country as the standard of comparison, because, being the lightest of all bodies, it has the smallest combining number, and if that be made = 1, the numbers of the other elements will generally be whole numbers, and thus we get rid of fractions as far as possible. If we were to make hydrogen = 10 or 100, the other numbers would have to be increased in proportion.

On the Continent, oxygen is made the standard, and is made = 100. Hydrogen then becomes 12·5; sulphur 200, chlorine about 450, and so on. The smaller numbers of the English scale are more easily retained, and, as already mentioned, there are fewer fractions. But any one who wishes to do so, can easily convert the numbers of the hydrogen scale into those of the oxygen scale. For this purpose, he has only to multiply the former by 12·5; and conversely, to reduce numbers of the oxygen scale to those of the hydrogen scale, we divide them by 12·5.

It is a very remarkable fact, and one no doubt connected with the intimate constitution of matter, that when hydrogen is made unity, nearly all the other elements are represented by whole numbers. In other words, their combining proportions are multiples of that of hydrogen by whole numbers. Dr Prout first advanced this as a law, which was much contested, and for a time it was supposed to be overthrown by the results of experiment. But as our methods of analysis have improved, it has been found that every year more elements are brought under Prout's law; and it seems probable that, as this improvement advances, that law will be ultimately found to apply universally. For the present, some important elements, such as chlorine and potassium, cannot be brought exactly under it, although we have used whole numbers in speaking of these elements, in order to avoid fractions. The true numbers of these elements, according to the best and most recent authorities, are given in the table.

It must be carefully remembered that these numbers are in no respect whatever theoretical, but represent the actual results of the best analyses. They are quite independent of all hypothesis, and it must be received as a simple observed fact, that the elements combine according to these numbers, or multiples or submultiples of them, whether we can explain it or not. It will be at once perceived that this important fact constitutes the only true foundation for chemistry as an exact science.

It cannot be doubted that this essential fact depends on some cause connected with the constitution of matter. But as we know nothing certain concerning the constitution of matter, nay, nothing whatever of matter, except its properties, that is to say, the various ways in which it affects our senses; so we are as little able to explain why the elements combine in fixed and invariable proportions, as we are to explain why or how the earth and the sun gravitate towards each other.

In all departments of natural science, we find ultimate facts, like this of definite proportions, or like gravitation, of which we know only that they exist; and those who imagine that, for example, they *explain* gravitation by saying that there exists an attraction between the gravitating bodies, which they call gravity, or the attraction of gravitation, delude themselves with words. To say this is merely to repeat the simple fact, that the bodies in question somehow tend towards each other, in different terms; and it furnishes not

even the shadow of an explanation of the phenomenon. Newton's celebrated law of gravitation was never intended, as some imagine, to explain gravitation, which no man can explain, but only tells us that all masses or portions of matter tend towards each other with a force which varies directly as the mass, and inversely as the square of the distance. This law enables us to measure and calculate the *force* of gravitation, but throws no gleam of light, nor does it pretend to do so, on the nature and mode of action of that force. *Why* do two bodies tend towards each other, and *how* is it effected? These are questions which Newton never attempted to answer, well knowing that they are beyond the reach of our faculties.

In like manner, the questions, Why do two elements combine chemically? How is their union effected? Why do they unite in fixed and definite proportions? have never been answered, and probably will never be answered, so long as our faculties remain the same. We can only say that they do unite, and that they unite according to certain laws which we can investigate and ascertain.

It is not wonderful that we should be utterly unable to answer such questions as we have stated, when it is considered that we cannot even define matter, or say what matter is. Of matter we know only the properties, not the essence.

But philosophers, in their eager anxiety to explain everything, have formed certain hypotheses as to the constitution of matter; and although none of these has been demonstrated to be true, and the knowledge of the true nature or essence of matter is, in all probability, beyond the reach of our faculties, yet some practical advantage may be derived from assuming as true a certain hypothesis concerning matter, from which we can deduce, in a simple and logical manner, the facts of combination in definite proportions, of combination in multiple proportions, and of proportional or equivalent numbers. This hypothesis is that which is known as the Atomic Theory. We shall now proceed to explain it in its application to chemistry; but the reader must carefully bear in mind, that although the Atomic Theory is only an hypothesis, assumed in order to furnish some explanation of the above-named facts, yet, whatever the ultimate fate of that hypothesis, and it is next to impossible that it should ever be demonstrated, the facts which it is intended to explain are observed and ascertained truths, which must remain, even were the atomic hypothesis proved to be false.

ATOMIC THEORY.

From the very earliest periods philosophers speculated on the nature and constitution of matter; and among the Greeks two opinions were held, both of which have ever since had supporters among those who studied natural science.

According to one opinion, matter is divisible *ad infinitum*, so that the smallest conceivable portion of matter may yet be divided into two or more smaller portions, and these again into others still smaller. Those who argue in favour of the infinite divisibility of matter appeal to experiment, which shows that matter is really divisible to an extent far beyond that of which our senses, aided by the microscope, can take cognisance. And they add, that we cannot conceive a mass of matter so small, that we are not able to imagine it to be divided into two halves, and these again each into two halves, and so on *ad infinitum*.

Now, all this is quite true. The actual divisibility of matter is amazingly great. One grain weight of gold can be beat out so thin as to cover with a perfect metallic surface 54 square inches; and gold is present, therefore, on every visible point of this large surface, even when examined by a high magnifying power. The one grain of gold, therefore, has been divided into at least as many minute parts as there are visible points in 54 square inches, viewed, let us say, under a magnifying power of 1000 linear. Platinum can be drawn out to a wire so fine as to be with difficulty seen. And these facts are as nothing compared to the division effected by chemical means. If one grain of iron or of copper be dissolved in an acid, and diluted with a gallon of water, the presence of the metal may be detected in every drop of the liquid. Now an ordinary drop weighs one grain, and in a gallon of water there are 70,000 grains. But each drop may be divided without difficulty into 1000 parts, since we can easily weigh $\frac{1}{1000}$th of a grain on our balances. And in every one of these parts we can detect the metal, even with the naked eye, by the use of proper tests. Again, under the microscope, each of these $\frac{1}{1000}$th parts of a grain of the liquid may be so magnified as to appear equal to the original drop, and of course may be again subdivided into 1000th parts, in which it cannot be doubted that we should still be able to detect the metal. Now, the gallon of liquid will yield 70 millions of minute drops, each weighing $\frac{1}{1000}$th of a grain; and 70,000 millions of the microscopic drops we have supposed to be derived from these under a high magnifying power. So that, if, as there is every reason to believe, the iron or copper can be shown to exist in each of these last particles, we shall have divided the one grain of metal, by chemical means, into 70,000,000,000 parts. And there is no reason to think that, even then, we should have reached the limit of actual divisibility, if there be a limit to it.

But all this does not prove that matter is *infinitely divisible*, for there may be a limit, though beyond the reach of our senses.

Now, the other opinion, which was held by some of the early Greek philosophers, is this: that matter is indeed divisible to a prodigious degree, but not infinitely; that there is a limit to divisibility, and that this limit depends on the constitution of matter. Matter is believed, by those who hold this opinion, to be formed of very minute particles which are called atoms, from two Greek words, signifying "that which cannot be cut or divided;" and when division reaches these, it can go no further, and must stop.

It is no doubt true, that however minute the supposed atoms may be, we can conceive of them as halved, and of the halves again as again divided. But while there is no limit to our *conception* of the smallness of atoms, this by no means proves that there may not be a limit to the actual divisibility of matter. To see this, let us consider what division really is; and we shall see that the knife, the hammer, the pestle, and the solvent, all agree in separating one part of a mass of matter from another, or in causing the parts to assume a new arrangement. The knife, which is perhaps the simplest agent of division, is a form of the wedge, and, being forced into the vacant space between two portions of a mass of matter, separates these. But that this may be done, there must be empty spaces between the parts of which the mass of matter is made up. And this is the case. Every mass of matter has multitudes of such empty spaces or pores, into which the dividing instrument penetrates. Matter itself is impenetrable; and when we penetrate a mass of it, we force the instrument into its pores, the matter being displaced or yielding on all sides, but not being itself penetrated. Consequently, if we suppose a mass of matter devoid of pores, it would not be possible for us to divide it, since matter is impenetrable, and there is no space for the instrument to enter. All natural matter, however, is porous, and consequently divisible; and the same is true of the smallest particles which our senses can appreciate.

But the very nature of the atoms, supposed by the second hypothesis to exist, is to be destitute of pores; to be in fact units of matter, entirely filling the space within their periphery, which the minutest fragment of ordinary matter does not. And when we have conceived a mass without pores, we have conceived an atom, that is, a particle which

cannot be divided, although we can conceive a particle of half its size, and so on.

According to this theory then, matter is made up of such atoms, or entirely solid, indivisible particles, which are not in absolute contact, but probably touch each other at one point only; and of the pores, or vacant spaces between them. When heat expands matter, it forces the atoms farther apart; when cold contracts it, they come nearer together. When cut or bruised, they are more or less completely separated from their original cohesion; when dissolved, the atoms are separated by the solvent. When beaten out thin, or drawn into fine wire, they are made to assume a new arrangement, either in many parallel lines or in one or a few such lines. In short, these atoms may be separated, or newly arranged, but they cannot possibly be divided; and therefore when, in the process of division, we come to the atoms, we must stop. They are, however, so very minute, that our means of division fail us before we reach them; so that the limit to divisibility in practice is short of that fixed by the nature of matter, according to this view.

For this reason we cannot demonstrate the actual existence of atoms, but the hypothesis which assumes their existence agrees perfectly with all the known phenomena exhibited by matter, whether physical or chemical, and more particularly with the laws of combination in fixed and multiple proportions; whereas the theory of the infinite divisibility of matter leaves these phenomena entirely unaccounted for.

It was Dalton who, reflecting on the facts of combination in definite proportion, first thought of applying to explain these the atomic hypothesis of the constitution of matter. In order to do this, however, we must assume, not only the atomic constitution of matter, but also three other hypotheses, namely, first, that the atoms of each element possess a weight which is invariable; secondly, that the weight of the atom of each element is different from that of all others; and, thirdly, that the elements combine atom to atom, and so forth.

If, for example, we assume that an atom of oxygen weighs 8 times as much as an atom of hydrogen; and if we further assume that 1 atom of oxygen unites with 1 of hydrogen to form water; it is easy to see that, in that case, water must contain oxygen and hydrogen in the proportions ascertained by experiment, namely, that of 8 parts by weight of oxygen to 1 part of hydrogen. And if we suppose 2 atoms of oxygen to combine with 1 atom of hydrogen, the compound thus formed must contain 16 parts, by weight, of oxygen to 1 of hydrogen, which, as we have seen, is the case in the deutoxide of hydrogen.

It must never be forgotten, that in applying the atomic theory to explain the facts of combination, we begin by a series of assumptions. We assume, first, that matter is formed of atoms; secondly, that these have fixed weights; thirdly, that these weights are different in different elements; and, fourthly, that when elements combine, they do so either atom to atom, or 1 atom to 2, 2 to 3, 1 to 3, &c. &c. All these are pure assumptions, which we cannot demonstrate; but these being made, and admitted, the whole facts of combination in fixed and multiple proportions may be naturally deduced from them, and indeed may even be predicted. This is the strongest argument in favour of the truth of these hypotheses, but yet they are not demonstrated truth; while the facts are facts, even if our hypotheses should be abandoned.

This, then, is what is called the Atomic Theory of chemistry. It supposes matter to be formed of exceedingly minute but indivisible particles or atoms, which possess weight, and which have different weights in different elements, but invariably the same weight in the same element. It is, however, impossible for us to know the absolute weight of these atoms in any case; all that we can do is to ascertain their comparative weights, on the further supposition that elements unite atom to atom, or in some very simple ratio. Thus, if we suppose that one atom of hydrogen and one atom of oxygen unite to form one (compound) atom or molecule of water; then, since we know as a fact that the proportions, by weight, in water, are 1 part of hydrogen to 8 of oxygen, we see that, admitting the suppositions we have stated, whatever be the absolute weight of an atom of hydrogen, an atom of oxygen must weigh 8 times as much. The smallest portion of water we can weigh may possibly contain a million of atoms of each element; but the number signifies nothing, so long as they are supposed to unite one atom with one atom; the relative weights of a million of atoms of each being the same as those of one atom of each element. If, then, we make hydrogen, as being the element whose atoms are the lightest in the standard, and express the relative weight of its atom by 1, the weight of the atom of oxygen will be 8.

In this way the relative weights of all the elements are ascertained, being referred to hydrogen as a standard; and the reader will at once see that these weights—atomic weights, as they are called—coincide with the combining proportions given in the table at p. 438. These numbers, therefore, are called indifferently atomic weights, combining proportions, or equivalent numbers, and, for shortness' sake, equivalents. They are mutually equivalent, because, as has been shown, when a body B leaves another A, to unite with a third C, the weight of B, at first united with a given weight of A, combines with or is equivalent to a weight of C, which is equivalent to or combines with the same weight of A. In other words, when one element is substituted for or replaces another, it is always in the proportion indicated by these numbers, or occasionally in a multiple of these. The terms, combining proportion and equivalent number or equivalent, are preferable to that of atomic weight, inasmuch as they simply express a fact, and do not involve any hypothesis. We shall therefore use, in general, the term equivalent, contracted, when desirable, into eq., as being unobjectionable.

The facts of multiple proportion follow naturally from the atomic theory. Thus, in the compounds of nitrogen and oxygen, the equivalents of these bodies being ascertained to be 14 and 8 (hydrogen = 1), we have only to suppose that,

In the first, 1	atom of nitrogen unites with	1 of oxygen.
In the second, 1		2 ...
In the third, 1		3 ...
In the fourth, 1		4 ...
In the fifth, 1		5 ...

and the resulting numbers will be as formerly stated.

In the case of such compounds as exhibit the ratio, in their composition, of 1 : 1·5, or 1 : 2·5, we cannot, without contradiction, speak of such compounds as formed of 1 atom of one element and $1\frac{1}{2}$ or $2\frac{1}{2}$ atoms of another. The half of an atom, of that which is indivisible, *ex hypothesi*, is a contradiction in terms. To avoid this, while using the terms of the atomic theory, we double the numbers and say that these compounds are formed by the union of 2 atoms of one element with 3 or with 5 of another. The two oxides of iron consist of

	Iron.	Oxygen.
Protoxide of iron	1 atom	1 atom
Sesquioxide or peroxide of iron	2 atoms	3 atoms

Alumina or sesquioxide of aluminum, sesquioxide of manganese, and sesquioxide of chromium, all likewise consist of 2 atoms or eqs. of metal and 3 of oxygen; and this analogy in composition is attended with remarkable analogy in properties.

It only remains to mention, that the compounds formed by elementary bodies combine together among themselves

precisely as the elements do. It rarely, if ever, happens, at least in inorganic or mineral chemistry, that elementary bodies and compounds combine together, unless in the case of such compounds as play the part of elements, and are hence called compound radicals. Few of these, however, are known, save in combination; and in general, we find that compounds unite with compounds, elements with elements. Thus, oxygen and sulphur unite with hydrogen and metals; but sulphuric acid, a compound of sulphur and oxygen, combines, not with hydrogen or metals, but with water and the oxides of the metals.

The combining proportion, atomic weight, or equivalent of a compound, is the sum of those of its elements. Thus water, formed of 8 parts of oxygen, and 1 of hydrogen, enters into combination in a proportion expressed by 9, the sum of these. Sulphuric acid, a compound of 1 eq. of sulphur and 3 eqs. of oxygen—that is, of 16 parts of sulphur, and 24 of oxygen, by weight—has the number $40 = 16 + 24$ for its equivalent or combining proportion. Potash, a compound of 1 eq. potassium, and 1 eq. oxygen, or (in round numbers) 40 parts of potassium and 8 of oxygen, has the equivalent $48 = 40 + 8$. And when potash and sulphuric acid combine, so as mutually to neutralize each other, they do so in the proportion of 48 parts of potash to 40 of sulphuric acid, forming neutral sulphate of potash, a compound of 1 eq. of each compound. There is another sulphate of potash, which is composed of 1 eq. of potash, 2 eqs. of sulphuric acid, and 1 eq. of water, and is termed the bi-sulphate of potash. So that the law of multiple proportions holds in regard to compounds as well as to elementary bodies.

We have no means of ascertaining the absolute size or volume of the atoms of any substance, and consequently we cannot directly find the relative volumes. But there are facts which indicate that the atoms of some elements are of the same size as those of certain others. For in compounds which crystallize, some of the elements may be removed and replaced by others, without affecting the form or angles of the crystal; which could hardly happen if the atoms of the replacing element differed much in size from those of the element which it replaces. This leads us to consider the subject of crystallization, and that of isomorphism, or the substitution of one element for another, without affecting the crystalline form of the compound.

This treatise is not the place for a full discussion of the subject of crystallization, which is one of great extent and importance, both in regard to chemistry and to mineralogy. Crystallography is now, in fact, a distinct branch of science.

It is sufficient for our purpose to state, that when substances are so placed as to assume the solid form, whether from the liquid state, or that of gas or vapour; and when this takes place slowly, and so that the particles or molecules can arrange themselves according to their natural tendencies,—they assume regular geometrical forms, which are termed crystals. Each substance which is capable of crystallizing, whether simple or compound, exhibits always the same form, except in a very few cases to be presently mentioned. This is so uniformly the case, that many substances may be recognised by this crystalline form alone.

Two circumstances require notice; first, that although the same substance always takes the same form (with the exceptions above alluded to), yet, within certain limits, the outward form may vary; that is, provided all the forms which occur are geometrically derivable from one, which is the fundamental form. Thus sea-salt crystallizes in cubes, but it also appears in regular octohedrons; fluor spar appears in cubes, in regular octohedrons, and in regular tetrahedrons; alum forms both cubes and regular octohedrons. This is because the cube, the regular octohedron, and the regular tetrahedron, constitute really but one fundamental form, termed the regular system, and are all geometrically and mechanically derivable one from the other. Calcareous spar forms rhombohedrons, but it also forms regular six-sided prisms and six-sided pyramids; also three-sided pyramids, and a prodigious number, amounting to several hundreds, of modifications of these forms; but all reducible, both theoretically and practically, to the fundamental rhombohedron of Iceland spar. In point of fact, then, calcareous spar exhibits only one form, but modified. Salt, alum, and fluor spar, also each exhibit geometrically but one form, variously modified. But although, as in calcareous spar, the extent of modification may be very great, it is never seen to crystallize in the form of the cube, regular octohedron, or regular tetrahedron, nor in any other form not geometrically derivable from its fundamental rhombohedron.

The second point is, that many different substances have the same crystalline form, as is seen in the case above quoted, of alum, salt, and fluor spar; to which may be added galena, iron pyrites, several metals, and many chlorides, bromides, iodides, fluorides, and sulphurets. This arises from the fact that the number of crystalline fundamental forms is very small compared with that of crystallizable bodies. It is chiefly in the regular system, that of the cube, that we see so many different substances assuming the same form, because the regular system is a very limited one; whereas in the other systems—in which the angles may vary, since we may have oblique rhombs or prisms of many different angles, but can have only one cube—there is much greater variety. We cannot, therefore, strictly say that each substance has a different form, but that each substance has a form to which it adheres, although other bodies may have the same.

It is evident that crystalline form must depend on the fact that the molecules of bodies are arranged in right lines, and at certain angles. When the right angle prevails, we have the cube and its derivatives, and the rectangular prism, which differs from the cube in the unequal length of its axes. When other angles occur, the result is an oblique prism, a rhombohedron, or an oblique octohedron, &c.

The great frequency of the cube and its derivative forms probably depends on the tendency of molecules of equal size to arrange themselves in lines at right angles to each other. But there are many instances of substances crystallizing in this form, which depend on isomorphism, that is, on the fact that, in certain compounds, one of the elements may be replaced by another without altering the crystalline form.

Chloride of sodium forms cubic crystals. But if the sodium be removed, and replaced by its equivalent of potassium, the new compound still crystallizes in cubes. Nay, if we remove the chlorine from the chloride of sodium, and replace it by bromine and iodine, the form is still unaltered. And if in the bromide or iodide of sodium we replace the sodium by potassium, the new salts assume the same form. Here, then, are six salts, the chlorides, bromides, and iodides of potassium and of sodium, which have the same crystalline form, the cube. These salts are said to be isomorphous.

To take another example. Alum, which is composed of sulphuric acid, alumina, potash, and water, forms regular octohedrons. But if the potash be replaced by soda or by oxide of ammonium, we obtain two salts, soda alum and ammoniacal alum, which are not to be distinguished from common alum by the form of their crystals. And, further, if the alumina, which is a sesquioxide, be replaced by the sesquioxide of iron, of manganese, or of chromium, we obtain three new alums of the same form. In each of these, as in common alum, the potash may be replaced by soda, or by oxide of ammonium, without affecting the crystalline form. So that we can have 12 alums, all differing in composition in some important point; yet all isomorphous.

Without quoting more examples, although many more might be adduced, it will be obvious from these that in each of the two groups the identity of form among the members

of the group depends on an analogy in composition; or, in other words, when one element can replace another without change of form, the replacing element is analogous in properties to that which it replaces; and, further, the function and position in the compound of the replacing element are the same as those of that for which it is substituted.

Thus, in chloride of sodium the chlorine is negative, the sodium positive; and while the positive sodium is replaceable by the positive potassium, a body singularly analogous to it, the negative chlorine is only replaceable by the negative iodine or bromine, the analogy of which to chlorine is very striking.

Alum consists of 1 eq. of the sulphate of a protoxide (sulphate of potash) with 1 eq. of the tersulphate of a sesquioxide (tersulphate of alumina), and 24 eqs. of water. The potash (oxide of potassium) in the sulphate, is replaceable by soda or oxide of ammonium, bodies entirely analogous; while the alumina (sesquioxide of alumina) can only be replaced by other sesquioxides, such as those of iron, manganese, and chromium, which are extremely analogous to it.

When we consider these facts, it would appear that the atoms, or molecules (groups of atoms) of the replacing body, besides their general analogy to the body replaced, are most probably of the same volume with those of the latter. This may help to explain how they can take the place of the expelled body, and yet not alter the form of the compound. For if their volume were different, it is not easy to see how the angles of the crystal should not be altered.

We can give no further explanation of isomorphism than this, that certain elements appear to be themselves isomorphous, and when this is the case they can replace each other in compounds without affecting the crystalline form.

Among the elements, various groups of such as are isomorphous, that is, with those of the same group, have been detected. These groups are given in the following table; and it will be seen that, as a general rule, the bodies in each group are not only isomorphous, but also in the highest degree analogous in properties.

The following isomorphous groups have been established, and the existence of more is highly probable:—

1.

Silver	Ag
Gold	Au

2.

Arsenious acid (in its unusual form)	AsO_3
Teroxide of antimony	SbO_3

3.

Alumina	Al_2O_3
Sesquioxide of iron	Fe_2O_3
.. chromium	Cr_2O_3
... manganese	Mn_2O_3

4.

Phosphoric acid	PO_5
Arsenic acid	AsO_5

5.

Sulphuric acid	SO_3
Selenic acid	SeO_3
Chromic acid	CrO_3
Manganic acid	MnO_3

6.

Hypermanganic acid	M_2nO_7
Hyperchloric acid	ClO_7

7.

Salts of potash	KO
Salts of oxide of ammonium	AmO
(Or ammonia NH_3 + water, $HO = NH_4O$)	

8.

Oxide of silver	AgO
Oxide of sodium	NaO

9.

Baryta	BaO
Strontia	SrO
Lime (in arragonite)	CaO
Oxide of lead	PbO

10.

Lime (in Iceland spar)	CaO
Magnesia	MgO
Protoxide of iron	FeO
„ manganese	MnO
„ zinc	ZnO
„ cobalt	CoO
„ nickel	NiO
„ copper	CuO
„ lead (in plumbo-calcite)	PbO

It is remarkable that groups of three are very frequent. Of course, where two or more elements have the same crystalline form, or are isomorphous, similar compounds of these elements must also be isomorphous. Thus, if potassium, sodium, and lithium be isomorphous, their protoxides, their chlorides, their sulphurets, must likewise be isomorphous, each with those of the same kind, chlorides with chlorides, &c.

What has been stated regarding the fact that substances of a totally different nature may have the same form, must not be confounded with isomorphous. Both alum and common salt crystallize either in cubes or in octohedrons, but they are not isomorphous; they merely happen to agree in crystalline form. But potash alum is isomorphous with soda alum, chloride of sodium with chloride of potassium, and so forth.

When we find two compound substances, of analogous properties to be isomorphous, this fact leads us to conclude that they are analogous in constitution. Thus, alumina is isomorphous with oxide of chromium, and analogous to it. Now, alumina is a sesquioxide, and we conclude that oxide of chromium is likewise a sesquioxide; a conclusion amply confirmed by other considerations. Selenic acid is found to be isomorphous with, and highly analogous to, sulphuric acid; arsenic acid is isomorphous with, and analogous to, phosphoric acid. We conclude, that since sulphuric acid is a teroxide and phosphoric acid a pentoxide, so selenic acid will prove to be a teroxide and arsenic acid a pentoxide. And this is found to be the case.

When two salts not isomorphous are in solution together, and the solution is evaporated, the two salts will crystallize either successively if of different solubility, or at the same time if of equal solubility, but quite distinct each from the other. The molecules of the one are only attracted by those of its own kind. The two salts may thus be easily separated. But if two isomorphous salts be dissolved, no matter in what proportion, every crystal will contain both, and they cannot be separated by crystallization. This is often a source of great inconvenience. Thus, when potash alum (common alum) is contaminated or adulterated with the isomorphous iron alum, it is impossible to purify it by crystallization. The iron alum is so similar to common alum that no one would suspect it, from its taste or colour, to contain iron, although in general the salts of sesquioxide of iron have a strong inky taste and brown colour. But when used in dyeing or calico printing, the presence of a little iron alum renders the alum totally useless, nay, injurious. It is the isomorphism of the two alums which causes them to adhere so firmly together.

In a few instances, as may be seen by the tables, the same element appears in two isomorphous groups; that is, in one set of compounds it is isomorphous with one group, in another set with another.

It has been stated, that the same body always crystallizes in the same form, insomuch that many bodies may be recognised by their crystals. But it was also mentioned that there were some exceptions to this general rule, and these are very curious.

We can conceive readily that the same composition might be found in two entirely different crystalline forms; for two compound bodies may have the same composition, and yet may differ in constitution, that is, in the arrangement of the same atoms. For example, if two compounds each contained 3 eqs. of the same metal and 4 of oxygen, they might yet be totally different; for one might be made up of two compounds, namely, one formed of 2 eqs. of metal and 2 of oxygen, and another of 1 of metal and 2 of oxygen—together, 3 of metal and 4 of oxygen; the other might be made up of two different compounds—of one containing 2 of metal and 3 of oxygen, and one containing 1 eq. of metal and 1 of oxygen—together, as before, 3 of metal and 4 of oxygen. And it would be quite natural that these compounds should have different crystalline forms.

But when we find elementary bodies crystallizing in two distinct forms not mutually derivable, it is not easy to un-

derstand how this should occur. Yet it does occur, and not unfrequently.

Sulphur exists in three distinct solid states, two of which are crystalline; carbon is found also in three solid states, two of them crystalline; and phosphorus occurs in two solid modifications, only one of which has yet been crystallized. These modifications of the same body, whether crystallized or not, in which different properties appear, are called allotropic modifications, and the phenomenon is called allotropism.

When sulphur is melted by heat, and allowed to cool, it forms small rectangular four-sided prisms. But when dissolved in bisulphuret of carbon, it forms large and broad crystals, which are oblique octohedrons. In its third allotropic state, sulphur, instead of being yellow, crystalline, and brittle, is brown, amorphous (that is, destitute of crystalline form), and tough.

Carbon, in the diamond, forms transparent regular octohedrons. In graphite it is opaque, black, and crystallized in scales or prisms. In charcoal, lamp-black, and anthracite, it is black and amorphous.

Phosphorus, in its ordinary state, is translucent, nearly colourless, very fusible, and it takes fire when heated to rather short of 100° Fahr. In its allotropic state, it is of a deep brownish-red, amorphous, much less fusible, and very much less inflammable.

In attempting to explain these remarkable facts, we must suppose, either that in one state the molecules contain more or fewer ultimate atoms than in another, or else that these atoms, if equal in number, are differently arranged. Hence the terms allotropic and allotropism, signifying that the atoms or the molecules are turned another way.

The occurrence of allotropic modifications of elementary bodies illustrates that hypothesis of the transmutation of elements formerly alluded to, but not explained. If, it is said, the ultimate atoms of an element, when grouped into molecules in one manner, exhibit certain properties, and when differently grouped (whether the difference consist in the number of atoms which go to form a molecule, or simply in their arrangement), acquire new properties, is it not possible, nay, even probable, that by some such difference of grouping one elementary body may be transformed into another? It has been stated by Dr Samuel Brown, that he succeeded in converting carbon into silicon, and iron into rhodium. And in the former case he supposes the molecule of silicon to be formed of three times as many atoms as that of carbon, the atoms being the same.

It must be admitted that such results are quite within the limits of possibility, and that the phenomena of allotropism, up to a certain point, favour the notion. But, in the first place, it must be remembered, that in the case of allotropic modifications, it is the physical properties which are chiefly affected, while the element retains its chemical characters. Thus, the physical properties of the diamond are as different as can well be imagined from those of lamp-black or charcoal. But the chemical characters are the same. In all its forms, carbon, when heated in oxygen or in air, burns, and is converted into carbonic acid gas; 6 parts of carbon invariably yielding 22 parts of carbonic acid. Moreover one allotropic form may, in general, be easily converted into another. Even the intractable diamond, under certain circumstances, passes into black, amorphous charcoal. Any one of the forms of sulphur may be converted into the other two. Ordinary phosphorus is converted, by a certain degree of heat, into the red variety; and this, when still more strongly heated, is reconverted into the ordinary form.

Now, if silicon be an allotropic form of carbon, it cannot be at pleasure either produced from carbon or reconverted into carbon. In the experiments where silicon is supposed to have been formed, only a fractional part of the carbon at best underwent the change, and this, as it were, accidentally, if the change really occurred.

But, secondly, the experiments of Dr Brown have not yielded in the hands of other chemists any such result; and chemists in general are of opinion, that the silicon found by Dr Brown must have been derived from the substances employed, in which it may have been accidentally present as an impurity.

Lastly, we may again point out that if an element is intended to perform any function in nature—and carbon, for example, has a most important function as the chief element of all organized tissues, as well as of all products of organic life—such element must possess a degree of stability and permanence, altogether inconsistent with the possibility of its being, under ordinary circumstances, transmutable into an element of different properties. Without this stability, neither compounds, nor analysis, nor chemistry could exist.

Various methods are employed in order to obtain bodies in the form of crystals, since crystallization is one of the best and most convenient means of purifying any substance. During crystallization the molecules of the same body attract each other, and seem to repel all others, except such as are isomorphous. When several salts are present in a solution, and it is evaporated till crystals appear, especially on cooling, the crystals of the different salts can be easily distinguished and separated.

Many substances crystallize best when their solution is boiled or evaporated down to the point at which it deposits its crystals on cooling, most substances being more soluble in hot than in cold liquids. But some, such as common salt, which are almost equally soluble in hot and in cold water, are best crystallized by boiling down the solution, while the crystals form in the hot liquid. Others crystallize when left to spontaneous evaporation; others, such as sulphur, are best crystallized, in one form at least, by fusion, and allowing the melted mass to cool slowly till half consolidated. The part still fluid being poured off, the interior is found lined with crystals projecting inwards.

Some bodies are crystallizable by sublimation, their vapour assuming at once the solid state.

A large proportion of those substances which crystallize from their solution in water, combine in the act of crystallizing, with a greater or less amount of water, which is called water of crystallization, being essential to these crystals. One eq. of dry or anhydrous alum takes up, in forming the ordinary crystals of alum, 24 eqs. of water. The carbonate, sulphate, and phosphate of soda, when crystallized, all contain more than half their weight of water. Such crystals are apt to lose part of their water on exposure to air, and to become opaque or fall to powder. This is called efflorescence. Salts containing no water of crystallization are called anhydrous. Such are the carbonate, sulphate, and nitrate of potash, common salt or chloride of sodium, and many others.

We have been led to consider briefly the subject of crystallization, from the relation of crystalline form to the atomic or molecular constitution of matter. There remain two other subjects connected with this, namely, combination by volumes in the gaseous state, and what is called the atomic volumes of different substances.

COMBINATION BY VOLUMES.

When we compare the quantities of different bodies which combine together, in the solid or liquid state, we cannot trace any simple or obvious relation between their volumes, such as exists between their weights. But when we compare the same substances in the gaseous form, the most simple relations at once become manifest.

Eight parts by weight of oxygen, as we know, combine with

1 part of hydrogen to form water. Now 8 parts of oxygen are in volume exactly equal to half of the 1 part of hydrogen. Or, in other words, 2 volumes (2 cubic inches, for example) of hydrogen unite with 1 volume of oxygen to form water; and the water thus formed, if measured in the state of gas or vapour, is equal in volume to the hydrogen, or 2 volumes. Two volumes of steam, therefore, contain their own bulk, or 2 volumes of hydrogen, and half their bulk, or 1 volume, of oxygen; so that 3 volumes of the gases, 2 of hydrogen and 1 of oxygen, when combined, are contracted into 2 volumes of steam or gas of water.

In all cases where two gases combine, we can trace some such simple ratio. The commonest are, 2 volumes to 1, the 3 volumes condensing into 2; 1 volume to 1, without condensation, and yielding, therefore, 2 volumes of the compound, as when 1 volume of chlorine and 1 volume of hydrogen unite to form 2 volumes of hydrochloric acid; and 1 volume to 3, the 4 volumes being condensed into 2. This is seen when 1 volume of nitrogen and 3 volumes of hydrogen unite to form 2 volumes of ammonia.

It will be seen that the doctrine of combination by volumes in the gaseous state confirms that of combination by weight, and equally establishes the fact that the combining proportions are fixed and invariable. The reason why we can trace relations so simple between the combining volumes of bodies in the state of gas must be connected with the molecular constitution of gases, and with the distance between their particles.

In solids, the force of cohesion preponderates over that inherent repulsive force which tends to remove the particles of matter farther apart. In liquids, these two forces are exactly balanced, so that the particles move freely in all directions. But in gases, the repulsive force or elasticity, which is derived apparently from the heat present in all matter, has entirely overpowered cohesion, and removed the particles to a much greater distance. Thus, in steam, the gas of water, the particles are so far asunder, that a given weight of water in that state occupies about 1400 times the volume it did in the liquid form.

Indeed, cohesion is so effectually overpowered in gases, that the particles would go on separating still further, in virtue of their mutual repulsion or elasticity, were it not for the force of gravitation, and also for the pressure of the atmosphere; which forces, in gases, hold an exact equilibrium with their elasticity. Heat enables elasticity to prevail, and thus causes gases to expand enormously in volume. Cold, on the contrary, contracts them. Diminished pressure has the same effect as increase of temperature; and increased pressure has the effect of cold on gaseous substances.

It appears probable, that if we could compare all gases under parallel circumstances as to heat and pressure, say, for example, at a hundred, or any other number of degrees above their respective boiling points (that is, the points at which they respectively assume the form of gas, overcoming cohesion), we should find that their particles are at equal distances; or, in other words, that equal volumes contain an equal number of atoms or of molecules. Or, if not, there would at least be a very simple ratio between them.

We have already assumed that the atoms of different elements have different weights; and on this supposition, if equal gaseous volumes contain an equal number of atoms, the weights of equal gaseous volumes must be to each other as the atomic weights. In that case, also, the densities of gases, if we adopt the same standard of reference, must coincide with the atomic weights.

Now this is actually, to a great extent, the case; and where the atomic weights and densities of gaseous bodies, both referred to hydrogen as unity, do not coincide, they at least exhibit some very simple multiple ratio. This is seen in the following table, in which the density as well as the atomic weight of hydrogen is made = 1:—

Gas or Vapour.	Specific Gravities.		Chemical Equivalents.	
	Air = 1.	Hydrogen=1.	By volume.	By weight.
Hydrogen...	0 0690	1·00	100	1·00
Nitrogen.....	0·9727	14·00	100	14·00
Carbon (hypothetical)	0·4213	6 00	100	6 00
Chlorine.	2·4700	35·50	100	35·50
Iodine....	8 7011	127·10	100	127·10
Bromine....	5·3930	80·00	100	80·00
Mercury.	6·9690	101·00	200	202·00
Oxygen..	1·1025	16 00	50	8·00
Phosphorus	4·3273	64 00	25	16·00
Arsenic............ ...	10·3620	150·00	25	37·50
Sulphur......	6·6480	96·00	16·66	16·00

The densities of gases are generally, however, referred to that of atmospheric air as unity, which conceals the relation between densities and atomic weights.

But it must not be overlooked that, although these facts may depend on the circumstance that equal gaseous volumes contain equal numbers of atoms, which are consequently at equal distances, and differ in the weight of the individual atoms; yet it is also quite possible that the difference in weight of equal gaseous volumes may depend on this, that equal volumes contain unequal numbers of atoms, or that the atoms are united into molecules of unequal size and weight, and placed at different distances in different bodies. It is even possible that the atoms of all bodies might be, individually, of equal weight, and that the difference in their combining proportions might depend on the number of atoms grouped in one molecule, and therefore on differences of size and weight in these complex molecules, not in the ultimate atoms. These are questions which cannot be resolved with certainty; but, if we assume that in gases equal volumes contain equal numbers of atoms, then the facts of combination by volumes follow naturally from the hypothesis.

In some substances, such as oxygen and sulphur, the density in the form of gas is such, that the combining weight is represented, not by a whole volume, but by a fraction, which in sulphur is $\frac{1}{6}$th of a volume. One volume of hydrogen unites with $\frac{1}{6}$th of a volume of the vapour of sulphur to form hydrosulphuric acid. If water be regarded as composed of 1 atom of oxygen and 1 of hydrogen, the atom of oxygen is represented by $\frac{1}{2}$ volume; whereas the atoms of hydrogen, chlorine, bromine, iodine, and nitrogen, are each represented by an entire volume. The table already given exhibits one or two instances, besides those of oxygen and sulphur, where the atom occupies only part of a volume. It is not easy to give a reason for this; but it is possible, that in the case of sulphur, for example, it depends on the existence of allotropic modifications. I. sulphur, in one of its three allotropic forms, has a vapour or gas six times denser than in another, it is evident that $\frac{1}{6}$th of a volume of the former will have the same weight as 1 volume of the latter. And it is certainly probable that each allotropic solid form has a density of vapour peculiar to itself; for there is reason to think that the different allotropic forms of an element differ in the number of atoms grouped in each molecule—a character which is likely to belong to such an allotropic modification, whether it be in the solid, liquid, or gaseous state.

ATOMIC OR EQUIVALENT VOLUMES.

The relation between the atomic weight and the specific gravity of bodies in the gaseous form has been briefly indicated in the preceding section. But the subject admits of being considered under different points of view, according to the notions entertained of the atomic constitution of

gases. On the supposition, for example, that the atoms, or ultimate particles of all elementary gases, with their surrounding spheres of heat, possess the same volume, all such gases would contain, in equal volumes, the same number of atoms. But as it is certain that compound gases do not, in all cases, contain the same number of atoms in equal volumes, it is quite possible that elementary gases may also differ in this respect; and, as above stated, the combining volumes of sulphur and of some other elements agree with this conclusion. It is therefore generally admitted that equal volumes of different elementary gases contain different numbers of atoms; that, for example, 1 volume of oxygen contains twice as many atoms, and 1 volume of sulphur (in the form of gas) six times as many atoms, as 1 volume of hydrogen, 1 volume of nitrogen, or 1 volume of chlorine.

This obviously implies that the atoms, with their spheres of heat, are of different sizes; and, to take the cases above mentioned, that the atoms of oxygen gas are $\frac{1}{2}$ the size, and those of sulphur $\frac{1}{6}$ the size of the atoms of hydrogen, nitrogen, chlorine, &c. This is what is called the *atomic volume* of gases. It is not meant that we can ascertain the absolute volume of the atoms, but the relative or comparative volume of the atoms or particles of two or more gases.

Now, since the specific gravity of a gas depends on the number of atoms in a given volume, and on the weight of these atoms, it is evident that the atomic weight, divided by the specific gravity, must give the (relative) atomic volume.

For example, let hydrogen be taken as the standard for the specific gravity of gases, as it is for their atomic weights; then the atomic weight of hydrogen, = 1, divided by its specific gravity, = 1, will yield the quotient 1 for the atomic volume of hydrogen. Again, the atomic weight of oxygen, = 8, divided by its specific gravity, = 16 (that of hydrogen = 1), gives the quotient 0·5, or $\frac{1}{2}$, as the atomic volume of oxygen; and the atomic weight of sulphur, = 16, divided by its specific gravity as gas, = 96 (that of hydrogen = 1), gives the quotient 0·1666 or $\frac{1}{6}$, as the atomic volume of sulphur.

We thus see that, on the supposition above adopted that the atoms of different gases differ in size, we can prove that, whatever be the size of an atom of hydrogen gas, an atom of oxygen gas must be half, and that of an atom of sulphur gas one-sixth that size.

It is further obvious, that the number of atoms in equal volumes must be inversely as the atomic volume; or that the specific gravity of a gas, divided by its atomic weight, will give the number of atoms in a given volume. Hydrogen being retained as the standard, then we have $\frac{1}{1} = 1 =$ the number of atoms in 1 volume of hydrogen:—$\frac{16}{8} = 2 =$ the number of atoms in 1 volume of oxygen; and $\frac{96}{16} = 6 =$ the number of atoms in 1 volume of gas of sulphur.

More briefly, the atomic volume and the number of atoms are the inverse of each other: so that we have $\frac{1}{6}$ and 6, $\frac{1}{2}$ and 2, 1 and 1.

If, while we make hydrogen the standard of atomic weights, we make air the standard of the specific gravity of gases, then we obtain, as quotients, a series of numbers equally comparable among themselves, but less simple and easy to retain than the above. We should have, for example, $1 \div 0·0694 = 14·409$ for hydrogen; $8 \div 1·1026 = 7·2554$ for oxygen; and $16 \div 6·9000 = 2·3188$, for the atomic volumes of hydrogen, oxyen, and sulphur respectively; and these numbers are to each other as 1, $\frac{1}{2}$, and $\frac{1}{6}$.

In the case of solids and liquids, the relation between atomic weight and specific gravity is far from being so simple, in consequence of the force of cohesion interfering with and disturbing the results. We cannot ascertain whether the atoms of solid bodies have the same size in different bodies or not; and we cannot tell whether the difference of specific gravity depends on a difference in the number of the atoms in an equal volume, a difference in the size of the atoms, or a difference in the size of the interstices between the particles, or possibly on two or more of these causes.

Some chemists assume that there are no interstices, but that the atoms wholly fill up the space within the circumference of the body. On this supposition, the atomic weight, divided by the specific gravity (in solids and liquids), must give the atomic volume. It is difficult, however, to admit the absence of interstices or pores in solids and liquids, if we consider them formed of atoms; and it is perhaps better to use the term *equivalent volume* instead of *atomic volume*.

The equivalent volume, then, of a solid or liquid is obtained by dividing the atomic weight (or rather equivalent number) by the specific gravity in the solid or liquid state. Water, the standard for the specific gravity of liquids and solids, may be made the standard of equivalent volumes.

Thus the atomic weight of water, = 9, divided by its specific gravity, = 1, gives the quotient 9 as its equivalent volume. The atomic weight of potassium, 39·26, divided by its specific gravity, 0·865, gives 45·387 for its equivalent volume; and the atomic weight of carbon, 6, divided by its specific gravity in the form of diamond, = 3·5, the quotient 1·717 for the equivalent volume of the diamond.

On the other hand, the specific gravity, divided by the atomic weight, gives the relative number of atoms in a given volume, and in the case of potassium this is $0·865 \div 39·26 = 0·0220$; in the case of carbon it is $3·5 \div 6·04 = 0·5794$. Finally, in the case of water, the relative number of atoms in a given volume, which may be made the standard, is $1 \div 9 = 0·1111$. If, for convenience, the number for water is made 1000, then that for potassium becomes 198·0, and that for carbon becomes 5215.

Assuming, likewise for convenience, the equivalent volume of water (the standard) to be (instead of 9) 1000, the equivalent volume of potassium becomes 5043, and that of carbon 191·666.

We thus perceive that the equivalent (or atomic) volume of carbon is about twenty-five times less than that of potassium, and that the number of atoms of carbon contained in a given volume is about twenty-five times greater than in the case of potassium. This compression of so large a number of atoms into a given volume may be the cause of the great hardness of the diamond.

The whole subject of equivalent volumes is full of interest; but, as chemists have only recently begun to study solid and liquid bodies in this point of view, our knowledge on the subject is still very imperfect and limited For what has lately been done, we are chiefly indebted to Kopp and to Schrœder.

Playfair and Joule have very lately published the first part of an elaborate investigation into the volumes occupied by bodies both in the solid form and when dissolved in water; and they have obtained results of an unexpected nature as well as of very great value.

The reader is referred to their paper in the Memoirs of the Chemical Society. Here we have only space to allude to the subject, and to mention that, among other curious results, these chemists have found that many salts, when dissolved in water, do not add to the bulk of the water more than is due to the water actually present in the salts. Thus, for example, alum, 1 eq. of which contains 23 equivalents of the elements potassium, aluminum, sulphur, and oxygen, besides 24 eqs. of water, dissolves in water without increasing its bulk more than the addition of the 24 eqs. of water must necessarily do; so that the 23 eqs. above mentioned occupy no additional space, and must either be contained in the pores or interstices of the water, or disappear altogether as far as the occupying of space is concerned, if water be supposed to have no pores.

They have further shown that when salts do add to the bulk of the water in which they are dissolved, the increase of the bulk corresponds to that of a volume, or some multiple of a volume, of water. It is evident that these and similar researches must soon greatly extend our knowledge of the mechanical constitution of matter.

There is another circumstance connected with chemical combination which must be briefly noticed. We have seen that bodies of different composition may have the same crystalline form, if they only differ by the substitution of one element for another isomorphous with it. But we find, also, that bodies have the same composition, that is, the same relative quantities or proportions of their elements, while their properties are totally different. In fact, this phenomenon in compound bodies is closely analogous to allotropism in elementary ones. It is not very frequent in inorganic chemistry, but very common in organic compounds. Thus cyanogen (a compound radical) forms with oxygen three compounds, cyanic acid, fulminic acid, and cyanuric acid, all three of which have exactly the same proportions of cyanogen and oxygen, but differ entirely in properties. This is accounted for by the fact, that in the first 1 eq. of cyanogen is united to 1 eq. of oxygen; in the second, 2 eqs. of cyanogen to 2 eqs. of oxygen; and in the third, 3 eqs. of cyanogen to 3 eqs. of oxygen. Such compounds are said to be polymeric, and correspond to those allotropic modifications of elements in which the molecules contain a different number of atoms.

But there are also cases in which not only the proportion but the absolute number of the elements is the same, while yet the properties are different. Aldehyde consists of 4 eqs. carbon, 4 eqs. hydrogen, and 2 eqs. oxygen. Acetic ether contains 8 eqs. carbon, 8 eqs. hydrogen, and 4 eqs. oxygen. It is, therefore, polymeric with aldehyde; and besides the difference in the number of atoms, there is an obvious difference in their arrangement. But butyric acid contains, like acetic ether, 8 eqs. of carbon, 8 eqs. hydrogen, and 4 eqs. oxygen. In these two compounds, then, the absolute number of atoms is the same, as well as their relative proportion; but the two bodies are totally different. This can only be explained by a difference in the arrangement of the same number of the same elements. Accordingly, in acetic ether they are arranged in two groups, acetic acid and ether, combined together; while in butyric acid two other groups, namely, dry butyric acid and water, are united. Such compounds are said to be isomeric, and sometimes metameric.

It is quite evident that both isomerism and polymerism are natural corollaries from the atomic hypothesis. If elements combine by atoms, it is obvious that a compound which contains twice or thrice as many atoms as another, or in which the same number or a multiple of it is arranged differently, might be expected, *a priori*, to exhibit different properties; and when we consider that, while there is no limit to the number of atoms which may combine, the slightest difference in arrangement will produce new properties as surely as a difference in number, we can see how vast is the number of different compounds producible on these principles from a few elements. This, as we shall see, is remarkably the case in organic chemistry.

Having now briefly noticed the most important laws of chemical combination, as well as various circumstances which are connected with it, it might be expected that we should offer some explanation of these phenomena. But we must confess that we are unable to do this. In the ordinary language of science, combination is attributed to a force called chemical attraction or affinity. But it is easy to see, that to say that two bodies combine together in consequence of chemical attraction or affinity between them, while it has the appearance of an explanation, really explains nothing, and amounts to no more than saying, that these bodies combine because they combine. For when we ask what is chemical attraction, we can obtain no other answer than that it is the force or cause in virtue of which different bodies unite; just as cohesion is the cause in virtue of which two or more portions of the same body are held together. But in neither case have we any knowledge of the real nature of this force, nor can we say with certainty that an attraction exists. The same is true of gravitation, and of all natural forces. We know not their nature, and we think that we explain them when we call them attractions, and speak of the attraction of gravitation, the attraction of cohesion, and chemical attraction. All that we really know is that a compound is formed, but how, or in what manner, we cannot tell; just as we see that particles cohere to form a mass, and that all bodies possess weight, without being able in the least to explain either phenomenon.

So true is this, that while some admit as many forces as there are different phenomena, others conceive that gravitation, cohesion, and affinity, as well as other so-called attractions, are all the result of one and the same force, acting under different circumstances, or at different distances. This, however, for the present, is purely hypothetical. We know nothing of natural forces except their effects, just as we know nothing of matter except its properties.

One hypothesis, however, concerning chemical attraction has enjoyed considerable popularity, and, as it has affected the language of the science, it is necessary to notice it.

It has long been known that bodies charged with electricity either attract or repel each other; and it has been found that there are two kinds or forms of electricity, which are called positive and negative, or vitreous and resinous. It is still a disputed point whether these are really distinct, or whether the positive be merely the excess, the negative the deficiency, of the same agent. However this may be, when two bodies are charged with the same kind of electricity, they repel; when charged with opposite kinds, they attract each other; that is, in the former case they move away from each other, in the latter they move towards each other.

Now, according to the electrical hypothesis, all bodies are naturally charged with one or the other electricity, and such as are negatively charged are supposed to attract such as are positively electric. Oxygen is said to be strongly negative, and such bodies as hydrogen and potassium as strongly positive. These form the extremes of an electric series of all the elements, which, when placed in their proper position, are found to be negative in regard to all lying between them and the positive end; and positive in regard to all between them and the negative end of the scale. Thus sulphur is positive with regard to oxygen, chlorine, bromine, iodine, and fluorine, all of which lie nearer the negative end; but negative to all the metals, and to hydrogen, which lie towards the positive end.

Now it is found that the strongest affinities, that is, the strongest tendencies to combine, really do exist between the most negative and the most positive elements, and that two bodies lying contiguous in the scale exhibit usually feeble affinity for each other, and when combined are very easily separated.

According to this electro-chemical hypothesis, every compound, however complex, consists of two constituents, one positive, the other negative, which unite because they are so.

One circumstance which seems to favour this hypothesis is this, that when any compound is decomposed by a current of electricity, the positive element always appears at the negative pole, and the negative element at the positive pole, which is supposed to be due to the fact, that unlike electricities attract each other, while like electricities repel each other.

On the other hand, there are circumstances which do not so easily admit of explanation. The elements, in their un-

combined state, exhibit no electricity of any kind, such as is supposed to be inherent in them. Again, when two oppositely electrified bodies attract each other, as soon as they touch, the electricity of both is neutralized and disappears, or becomes insensible. Now, if two elements combine, in virtue of their opposite electricities, when combined these electricities must be neutralized and disappear. What, then, retains the elements in combination, since we cannot suppose them, after contact, to continue powerfully negative and positive? This difficulty renders the electro-chemical hypothesis very doubtful.

Nevertheless, there is a very decided relation between electricity and chemical action. For every case of chemical action produces electricity, and this is the foundation of the galvanic pile and battery. Moreover, electricity, in certain circumstances, promotes chemical action, while in others it causes decomposition. It has been shown by Faraday, that the electricity of a galvanic arrangement may be accurately measured by the amount of decomposition it effects. We cannot tell what is the real nature of the connection between chemical action and electricity, but that relation exists. Indeed, it would seem that force, using that term in its most general sense, may take the form either of chemical force or of electricity, and may also be transformed into mechanical force, or into heat, and that any one of these, as also light and magnetism, is capable of taking the form of any of the others.

This seems to indicate that all these forms of energy are modifications of one and the same power. This is a subject of much interest, both theoretically and practically. It has been much studied of late, and promises to clear up our views on these important points.

In the meantime, the electro-chemical doctrine is the foundation of the prevalent or dual view of chemistry, and of the arrangement usually followed, as will be more fully explained when we come to treat of the elements in their order.

Before doing so, however, it is necessary to explain the system of notation employed by chemists, without a knowledge of which all chemical works would be utterly unintelligible. This notation is a system of abbreviation, the symbols employed being simply the names of the elements contracted into one or two letters. No other signs are used except ciphers, and the signs $+$, $-$, and $=$, in their usual acceptation, signifying addition, subtraction, and equality.

The symbols for the elements are the first letters of their Latin names; and where two or more have the same initial letter, a second letter is added to distinguish them. Thus O is the symbol for oxygen, H for hydrogen, C for carbon; while osmium is represented by Os, mercury (hydrargyrum) by Hg, chlorine by Cl. These symbols are all given in the second column of the table of equivalents, p. 438

The symbol of an element, by itself, signifies an equivalent of that element. O stands not for oxygen abstractly, but for 1 eq., or 8 parts by weight of oxygen (hydrogen = 1).

A cipher subjoined to the symbol multiplies it. Thus O_3 means 3 eqs. of oxygen, Cl_5, 5 eqs. of chlorine, &c.

Two symbols placed side by side express a compound of 1 eq. of each element. Thus, HO means water, a compound of 1 eq. of hydrogen and 1 of oxygen. HCl, hydrochloric acid, 1 eq. of hydrogen and 1 of chlorine; KCl, chloride of potassium, 1 eq. of potassium (kalium) and 1 of chlorine, &c. &c. Two symbols joined by the sign $+$, signify the same thing; but for the sake of brevity the former notation is preferred for binary compounds.

If a cipher be attached to the right of and below one of the symbols, it multiplies that symbol only. Thus, SO_3 is sulphuric acid, 1 eq. of sulphur and 3 of oxygen; PO_5 is phosphoric acid, 1 eq. of phosphorus and 5 of oxygen; Cu_2O is suboxide of copper 2 eqs. of copper and 1 of oxygen; Fe_2O_3 is sesquioxide of iron, 2 eqs. of iron and 3 of oxygen.

When two binary compounds, that is, compounds of two elements, are placed side by side, or separated only by a comma, or united by the sign $+$, this means a compound of the two. Thus HO, SO_3 is hydrated sulphuric acid, composed of 1 eq. of water and 1 of sulphuric acid; and it may be written either HO, SO_3, or $HO + SO_3$; but the comma is preferred to indicate the union of two binary compounds.

When three or more binary compounds are combined, it sometimes becomes advisable to use the sign $+$ in addition to the comma. Thus $KO, HO, 2\,SO_3$, or $KO, SO_3 + HO, SO_3$, equally represent the bisulphate or acid sulphate of potash; which is viewed as either composed of 1 eq. of potash (KO), 1 of water, and 2 of sulphuric acid, or 1 eq. of neutral sulphate of potash, and 1 eq. of hydrated sulphuric acid.

When a large cipher is *prefixed* to the symbol of a compound, or to those of several compounds, it multiplies all to the next comma or $+$ sign; as in the first formula for bisulphate of potash above given, in which $2\,SO_3$ means 2 eqs. of sulphuric acid. If written thus, $2\,SO_3, KO, HO$, the 2 multiplies only the SO_3. When it is required to multiply the whole of a complex formula, as often happens in the chemical equations to be presently described, the symbols to be multiplied are included within brackets. Thus $2(KO, SO_3)$ means 2 eqs. of neutral sulphate of potash; while $2\,KO, SO_3$ would signify a compound of 2 eqs. of potash and 1 of sulphuric acid.

Such are the whole of the rules for the use of our chemical notation in expressing the view we entertain of the constitution of chemical compounds. This notation, or these formulæ are very simple, very brief, and thoroughly clear and unmistakable. They are mere abbreviations, and, as such, are of the utmost value, as enabling us to express, in very small space, and in a form very obvious to the senses, a number of facts concerning the relative weights and the supposed arrangement of the combined elements, which would, if written fully, occupy pages of print. To take an example, alum, a complex salt, is represented by the formula—

$$KO, SO_3 + Al_2O_3, 3\,SO_3 + 24\,HO.$$

This tells us that chemists consider alum as composed of 1 eq. of neutral sulphate of potash, 1 eq. of neutral tersulphate of alumina (composed of 1 eq. of alumina, a sesquioxide, and 3 eqs. of sulphuric acid), and 24 eqs. of water. This is seen at a glance, but we see also much more. We see that in the sulphate of potash the oxygen of the acid is 3 times that of the base; and that in the sulphate of alumina, where the base contains 3 eqs. of oxygen, the oxygen of the acid is still 3 times as much, since there are 3 eqs. of the acid to 1 of the base. We see that 1 eq. of alum contains 1 eq. of potassium, 2 of aluminum, 4 of sulphur, 24 of hydrogen, and 40 of oxygen; that all the hydrogen is in the form of water, &c. &c. And all this, and much more, is to be easily seen in a formula which occupies but half a line.

We see, then, that our symbols and formulæ enable us to express, in the most compendious form, the fullest and most exact account of what we believe to be the constitution of any compound. Should we require to express a different view, it is done with the utmost facility, and the different or opposite views are presented to the eye in the most distinct and intelligible manner. Thus, oil of vitriol, if considered as being hydrated sulphuric acid, a compound of the dry acid and water, is represented by HO, SO_3 But if considered as a compound of hydrogen and not of water, its formula becomes H, SO_4, which means that hydrogen is here supposed to be combined with the hypothetical compound radical SO_4; a view which is regarded

as more probable than the other. In like manner, sulphate of potash may be viewed either as KO, SO_3, or K, SO_4. It is impossible for us to ascertain with certainty which of these views is the true one, because in both cases the resulting composition is the same. It is only the arrangement or constitution which differs. But the two opinions are quite as clearly and far more briefly expressed in the formulæ than they can be in words. Whatever view can be imagined as to the constitution of any compound, however complex, it is just as easily expressed by symbols, and they are therefore in constant use. The student must, therefore, in the outset, make himself familiar with them, which is very easily done.

These, however, are not nearly the whole of the advantages derived from the use of symbols and formulæ. They enable us, besides, to express, in by far the most convenient and the clearest manner, the results, real or supposed, of any chemical change among substances of known composition. This is done by means of equations, which are just as simple as the formulæ themselves.

The first half or section of the equation contains the formula or formulæ of the substance or substances which undergo change. The second consists of the formulæ of the substances formed or liberated by the change. These must of course be equal, otherwise the explanation is false or imperfect.

The action of potassium on water is thus represented:—

$$K+HO=KO+H.$$

This shows that potassium seizes the oxygen of water; while the hydrogen is liberated. Again, the action of hydrochloric acid on oxide of silver is thus represented:—

$$HCl+AgO=HO+AgCl.$$

Here the hydrogen of the acid and the oxygen of the oxide unite to form water; while the chlorine of the acid and the metal of the oxide combine to form chloride of silver.

The more complex the example, the more useful is the equation, as placing the whole clearly before the eye. When hydrochloric acid acts on peroxide of manganese the equation is as follows:—

$$MnO_2+2HCl=MnCl+2HO+Cl.$$

This shows that for 1 eq. of peroxide of manganese 2 eqs. of hydrochloric acid are required; that 1 eq. of chlorine unites with the metal, forming chloride of manganese; that the 2 eqs. of hydrogen form water with the 2 eqs. of oxygen; and that 1 eq. of chlorine is set free. In this way chlorine is prepared.

Another method for obtaining chlorine consists in the action of sulphuric acid on chloride of sodium (sea-salt) and peroxide of manganese. The equation is

$$NaCl+MnO_2+2\,SO_3=NaO, SO_3+MnO, SO_3+Cl,$$

which tells us that 1 eq. of salt, 1 of peroxide of manganese, and 2 of sulphuric acid, yield 1 eq. of sulphate of soda, 1 eq. of sulphate of protoxide of manganese, and 1 eq. of chlorine. This is the manufacturing process.

Such equations offer another great advantage, that, namely, of enabling us to calculate precisely how much of the materials we ought to use, and how much of the products we ought to obtain.

Nitric acid is prepared by the action of oil of vitriol, or hydrated sulphuric acid, or nitrate of potash, according to the equation—

$$KO, NO_5+2\,(HO, SO_3)=(KO, HO, 2\,SO_3)+HO, NO_5.$$

Here 2 eqs. of oil of vitriol act on 1 eq. of nitrate of potash, yielding 1 eq. of bisulphate of potash and 1 eq. of hydrated nitric acid.

Now since the equivalent of a compound is the sum of those of its elements, the equivalent of nitrate of potash must be (in round numbers)

Nitrate of Potash.	Oil of Vitriol.
$K = 40$	$S = 16$
$N = 14$	$H = 1$
$O_6 = 48$	$O_4 = 32$
$KO, NO_5 = 102$	$HO, SO_3 = 49$
	and $2\,(HO, SO_3) = 98$

Hence we must use, for 102 parts of nitrate of potash, 98 of oil of vitriol. The products are—

Bisulphate of Potash.	Nitric Acid (hydrated).
$K = 40$	$N = 14$
$S_2 = 32$	$H = 1$
$H = 1$	$O_6 = 48$
$O_8 = 64$	
$KO, HO, 2\,SO^3 = 137$	$HO, NO_5 = 63$

On the one hand the materials employed, 102 parts of nitrate of potash, and 98 of oil of vitriol, amount to 200 parts. On the other, the products, 137 parts of bisulphate of potash, and 63 of hydrated nitric acid, also amount to 200 parts. Any other proportion of the materials would imply waste or loss of a part.

Should any theoretical view of a process require to be tested, it may be done by comparing the amount actually obtained of any one or all of the products with that indicated by the proper equation. Should they differ very much, it is a proof, if nothing have been lost in the process, that the equation, and consequently the theory on which it rested, is erroneous.

The use of these equations, and the calculations connected with them, enable us to see clearly how it happens, that when two neutral salts decompose each other, the resulting salts are also neutral. Thus, if sulphate of potash and nitrate of baryta, two neutral salts, act on each other, they yield nitrate of potash and sulphate of baryta, which are also neutral, according to this equation—

$$KO, SO_3+BaO, NO_5=KO, NO_5+BaO, SO_3.$$

Here the equivalents are, before the change,

$$KO, SO_3=\begin{cases}KO = 48\\ SO_3 = 40\end{cases}\quad 88 \qquad BaO, NO_5=\begin{cases}BaO = 76\\ NO_5 = 54\end{cases}\quad 130$$

After the change, we have

$$KO, NO_5=\begin{cases}KO = 48\\ NO_5 = 54\end{cases}\quad 102 \qquad BaO, SO_3=\begin{cases}BaO = 76\\ SO_3 = 40\end{cases}\quad 116$$

Now it will be seen that the quantity of potash which neutralizes 40 parts of sulphuric acid, namely 48 parts, is exactly sufficient to neutralize 54 of nitric acid; and that the quantity of nitric acid which neutralizes 76 of baryta, namely 54 parts, exactly suffices to neutralize 48 parts of potash. In short, as before stated, the equivalent numbers are proportional, and this is seen in the equations without the trouble of calculation.

From the more complex nature of organic compounds, the formulæ which express them are more complex, but in principle precisely the same. Many organic compounds contain 3 or 4 elements: thus, oxalic acid is $C_2\,O_3$, HO, or, according to the most recent researches, double this, $C_4\,H_6$, 2 HO, which implies, that in the first formula it is a monobasic acid, containing 1 eq. of basic water, replaceable by bases; and in the second that it is bibasic, that is, has 2 eqs. of replaceable water. Acetic acid is $C_4\,H_3\,O_3$ HO; butyric acid, $C_8\,H_7\,O_3$, HO; benzoic acid $C_{14}\,H_5\,O_3$, HO. Oxide of ethyle or ether is $C_4\,H_5\,O$; alcohol, its hydrate, is $C_4\,H_5\,O$, HO; all these consist of 3 elments, carbon, hydrogen, and oxygen, the number of eqs. of which is often much larger. Thus stearic acid is $C_{34}\,H_{33}\,O_3$, HO; Melissic acid is $C_{60}\,H_{59}\,O_3$, HO. Then we have hydrocyanic acid, which is $C_2\,NH$; cyanic acid, $C_2\,NO$, HO; cyanuric acid, $C_6\,N_3\,O_3$, 3 HO; urea, $C_2\,H_4\,N_2\,O_2$; gly-

cocine, $C_4 H_5 NO_4$; leucine, $C_{12} H_{13} NO_4$; ethylamine, $C_4 H_7 N$; phenylamine, $C_{12} H_7 N$; quinine, $C_{20} H_{12} NO_2$; indigo, $C_{16} H_5 NO_2$; gelatine, $C_{82} H_{67} N_{13} O_{32}$; albumen, $C_{216} H_{169} N_{27} S_2 O_{65}$, &c., all of which contain nitrogen, which in hydrocyanic acid only is without oxygen, and in albumen is also associated with sulphur. We have given these organic formulæ to show both their somewhat complex nature, and the extreme facility and conciseness of the mode of notation. It will be seen that all these organic compounds are formed from a very small number of elements, never, if we exclude the incombustible part or ash, exceeding 5, and most frequently only 3, carbon, hydrogen, and oxygen, or 4, these with the additions of nitrogen. The same four elements form innumerable organic compounds.

The most complicated changes in organic chemistry are just as easily expressed. When sugar undergoes fermentation it yields alcohol and carbonic acid, as in the equation—

Dry Grape Sugar.		Alcohol.		Carbonic Acid.
$C_{12} H_{12} O_{12}$	$=$	$2(C_4 H_5 O, HO_2)$	$+$	$4\, CO_2$.

In many organic compounds, and, indeed, in entire series of compounds, we admit the existence of certain permanent groups, which are called compound radicals, and which play exactly the part of elementary bodies. It is often convenient to adopt a single symbol for each such compound radicle; for this gives to its compounds the simple formulæ of inorganic bodies. The following are some of the admitted compound radicals:—

		Symbol.			Symbol.
Cyanogen	$= C_2 N$	$=$ Cy	Benzoyle	$= C_{14} H_5 O_2$	$=$ Bz
Methyle	$= C_2 H_3$	$=$ Me	Acetyle	$= C_4 H_3$	$=$ Ac
Ethyle	$= C_4 H_5$	$=$ Ae	Formyle	$= C_2 H$	$=$ Fo

We do not assert that all so-called compound radicals actually exist in a separate state, although cyanogen and several others do so. But even if none of them did, we derive, from assuming their existence, the advantage of being able to represent a series of compounds related together in a very simple manner. Thus the compounds of cyanogen above named may be written $H Cy$, $Cy O$, HO, Cy_3, O_3, $3\,HO$. Those of ethyle (ether and alcohol) become $Ae\,O$ and $Ae O$, HO. Acetic acid becomes $Ac O_3$, HO, and benzoic acid $Bz O$, HO. Ethylamine takes the formula $NH_2 Ae$, or $Ad\,Ae$ ($Ad = NH_2$, stands for amide); perchloride of formyle or chloroform, $C_2 H Cl_3$ may be also written $Fo Cl_3$. In this way, even very complex compounds may be expressed as simply as the simplest inorganic bodies. Compare hydrocyanic acid, $H Cy$ with hydrochloric acid, $H Cl$; oxide of ethyle, $Ae O$, with oxide of potassium; acetic acid (hydrated) $Ac O_3$, HO, with hydrated sulphuric acid, SO_3, HO_3; and hyduret of benzoyle, $C_{14} H_5 O_2$, H or $Bz H$, with sulphuretted hydrogen SH.

Organic acids and bases are sometimes written simply with the initial letter of their names, above which is placed $+$ for a base, and $-$ for an acid. Thus $\overset{+}{Q}$ means quinine, $\overset{+}{M}$, morphine. $\overset{-}{T}$ stands for tartaric, and $\overset{-}{C}$ for citric acid.

CHEMICAL NOMENCLATURE.

Before proceeding to the description of the elements and of their compounds, it is necessary to say a few words on the nomenclature employed. This is far from being in a satisfactory state. It was first proposed about the time of Lavoisier's discoveries, and was founded on his theory of combustion. But the science has made, of late years, such rapid progress, that we can no longer employ the same principles of nomenclature, at least in many cases; and yet, as no better system has hitherto been proposed, the old one retains its place, with a large number of heterogeneous additions.

The elements are named on various principles. Such as have long been known retain their old names, as iron, sulphur, &c.; those of more recent discovery have been named either from some property, or, in the case of some metals, after some of the planets, &c. Thus, oxygen is so named because it was supposed to be the cause of acidity in compounds; hydrogen, from its producing water; nitrogen, from producing nitric acid; chlorine and iodine, from their colour; bromine, from its smell, &c. Of the metals, potassium, sodium, magnesium, calcium, strontium, from occurring in potash, soda, magnesia, lime (calx), strontia, &c.; barium, from the weight of its compounds; cerium, mercury, palladium, selenium, tellurium, and uranium, after the heavenly bodies—Ceres, Mercury, Pallas, the Moon, the Earth, and Uranus. The remaining elements are named on similar principles. The Latin names of all metals end in *um*, as aurum, argentum, cuprum, plumbum; for gold, silver, copper, and lead. Only one non-metallic body, selenium, ends in *um*, but this is because it was at first supposed to be a metal. On the whole, the names of the elements are arbitrary, and the less significant they are the better. Oxygen, for example, is no longer considered as the only producer of acids, for many acids are known which contain no oxygen, and the name would be almost better applied to hydrogen, which forms many acid compounds.

In naming binary compounds, we first observe whether they are acid or not. If acid, they are called acids, and the name of one of the elements is prefixed, with the termination *ic* or *ous*. Thus we have sulphuric acid, carbonic acid, phosphoric acid, nitric acid, and many others.

When there are two acids containing the same element united to oxygen, that which contains less oxygen has the termination in *ous*. Thus sulphurous and nitrous acids contain less oxygen than sulphuric and nitric acids.

Should other acids containing the same elements be discovered, the prefix *hypo* is employed in addition. Thus, after sulphurous and sulphuric acid had long been known, other acids were discovered, one of which is called hyposulphurous, another hyposulphuric acid; which means that the former contains less oxygen than sulphurous, the latter less oxygen than sulphuric acid. We have also hyponitrous, hypophosphorous, hypochlorous acids, and hypochloric acid.

When a compound of oxygen is not acid, it is called an oxide of the element which is combined with oxygen. Water is an oxide of hydrogen, and we have oxides of nitrogen, carbon, and all the metals.

An oxide consisting of 1 eq. of each element is called a protoxide. Water is protoxide of hydrogen, and there are protoxides of almost all the metals, as protoxide of lead, of iron, of manganese, &c.

When the proportion in an oxide is that of 1 eq. of the other element to $1\frac{1}{2}$ of oxygen, that is, 2 to 3, it is called a sesquioxide, as, sesquioxides of iron, aluminum, chromium, manganese.

When we find 1 eq. to 2 of oxygen, it is called a deutoxide or binoxide, and in some cases peroxide, meaning the oxide having most oxygen; as deutoxide of hydrogen, of nitrogen, of tin, of manganese, of lead; the two latter, as well as the first, being often called peroxides.

When the proportion is 1 to 3, the compound is called a teroxide, as teroxide of antimony.

When a compound, instead of oxygen, contains chlorine, bromine, iodine, or fluorine, it is called a chloride, bromide, iodide, or fluoride; and we have protochlorides, protobromides, deutochlorides, &c., terchlorides, and perchlorides or perbromides, periodides, &c., just as with oxides.

When the compound contains, instead of oxygen, chlorine, &c., sulphur, phosphorus, carbon, selenium, &c., it is called a sulphuret, phosphuret, carburet, selenuret, &c.

Examples—Chloride of sodium, bromide of carbon, iodide of lead, deutochloride or bichloride of mercury, protochloride of mercury, deutoiodide of mercury, terchloride of antimony, terfluoride of silicon, perchloride of manganese,

sulphuret of potassium, phosphuret of lead, carbonet of iron, seleniuret of copper, bisulphuret of carbon, bicarburet of nitrogen, tersulphuret of arsenic, protosulphuret of iron, pentasulphuret of potassium, &c. &c.

Such is the method employed in naming binary compounds.

When two binary compounds combine, this is expressed in the name. If one of them be acid, as commonly happens, and the other basic or alkaline, the name of the acid goes first, with the termination in *ate* for an acid in *ic*, that in *ite* for an acid in *ous*. Thus sulphuric acid and potash (oxide of potassium) form sulphate of potash; nitric acid and oxide of lead, form nitrate of (oxide of) lead. Sulphurous acid and ammonia form sulphite of ammonia.

When there are 2 or 3 eqs. of acid, or more, to 1 eq. of base, we prefix *bi*, *ter*, *quadri*, &c. Thus we have bisulphate of potash, tersilicate of lime, quadroxalate of potash.

When there are 2, 3, or more eqs. of base to one of acid, the prefixes *di*, *tri*, &c., are employed; as dinitrate of mercury, trisilicate of potash.

When we wish to express, in general, excess of acid over base, we use the prefix *super*, as supercarbonate of lime; for excess of base, generally, we use *sub*, as subnitrate of mercury, subsulphate of mercury. In double salts we express the names of both bases, as sulphate of alumina and potash, oxalate of chromium and potash.

Observe, that instead of sulphate, nitrate, &c., of oxide of lead, oxide of iron, &c., we say, for shortness sake, sulphate of lead, nitrate of silver, &c. But it is always understood that the compound contains an oxide of the metal united with the acid. The oxides of potassium, sodium, lithium, barium, strontium, calcium, magnesium, aluminum, yttrium, glucinium, zirconium, and thorinum, are also called potash, soda, lithia, baryta, strontia, lime, magnesia, alumina, yttria, glucina, zirconia, thorina, and we speak of the salts of potash, soda, &c., instead of saying the salts of oxide of potassium, or of potassium.

It is in organic chemistry that the chief difficulties of nomenclature occur. In the case of organic acids they are named like inorganic acids, as acetic, butyric, oxalic, tartaric, citric acids, &c., but generally from the source which yields them. The organic bases are made to terminate in *ine*, as morphine, quinine, nicotine, glycocine, methylamine, ethylamine, dimethylamine, triethylamine, &c., as will be fully explained when we come to treat of them.

Compound organic radicals generally terminate in *yle*, as ethyle, methyle, cetyle, acetyle, formyle, benzoyle, and their compounds, are named accordingly; as oxide or chloride of ethyle, terchloride of formyle, hyduret of acetyle, hyduret of benzoyle, cyanide of ethyle, &c.

But with these and a few similar exceptions, the enormous number of organic compounds have been named without system, and constitute a perfect chaos, which will continue to annoy chemists until a rational and consistent method of nomenclature shall be devised. An attempt has been made by Gmelin; but the names, though systematic, are so uncouth, and in many cases so liable to be confounded together, that no one has adopted Gmelin's system.

We are now prepared to enter on the consideration of the elements individually, and of the compounds formed by their union. In order to facilitate the statement and comprehension of the facts, some arrangement must be followed; and, although the science is not sufficiently advanced to admit of a perfectly consistent classification, yet, by attending to the observed analogies, we may obtain a very convenient working arrangement.

It is generally founded on the electro-chemical relations of the elements, as already explained; but it coincides very closely with the obvious and natural division of the elements into metals and non-metallic bodies or metalloids, in the first instance; and then the further subdivision of both, according to the degree of affinity for oxygen.

When any binary compound of oxygen is decomposed by an electric current, the oxygen *invariably* appears at the positive pole, while the other element goes to the negative pole. This proves that oxygen is always negative compared to all other elements. In like manner, hydrogen always goes to the negative pole, as do also such metals as potassium and sodium. Now, as there are no substances which have so strong an affinity for oxygen as these three, it is plain that the degree of affinity is measured by the degree of electric opposition between two elements. At one end of the electro-chemical scale, therefore, we place oxygen as being the most negative of all bodies; at the other, hydrogen, potassium, and sodium, as being the most positive. All the other elements are placed according to their relation to oxygen on the one hand, to hydrogen and the alkaline metals on the other.

Thus chlorine is positive in relation to oxygen, for when a compound of these elements is decomposed by the current, the chlorine appears at the negative pole; but it is negative in relation to all metals, and to all or nearly all the non-metallic bodies except oxygen. The true position of fluorine is unknown; but it is intensely negative, and must stand very near to oxygen and chlorine, perhaps between them, perhaps even outside of oxygen, as it may prove to be negative in regard to that element. But with the exception of this doubtful case, chlorine is negative to all but oxygen, and therefore ranks next to it. Bromine and iodine follow closely, and are positive to oxygen and chlorine, negative to all the rest, bromine being the more negative of these two. Carbon, sulphur, phosphorus, selenium, boron, and silicon, are all strongly negative with regard to hydrogen and metals, but yet even more strongly positive to oxygen; they exhibit, therefore, strong affinities on both sides. Nitrogen holds a nearly isolated position, having affinities of considerable energy to all the other classes of elements, but not belonging decidedly to any. This is a most important character, which is essentially necessary to fit nitrogen for the important part it has to perform as an indispensable element of all living organisms or tissues.

The metals, as a class, are positive to oxygen, chlorine, and its congeners, sulphur, and the like; but their positive energy varies from the highest in potassium, sodium, and lithium, to the lowest in gold, platinum, and iridium. Consequently these latter metals, and others like them, are negative to such as potassium. Such metals as mercury, copper, lead, zinc, iron, &c., hold an intermediate position, and are negative to such as potassium, positive to gold, &c. It is difficult to arrange the individual metals accurately, but they are easily divided into groups, as we shall presently see.

The only so-called non-metallic element which has a place among the most intensely positive is hydrogen. But there is much reason to think that hydrogen, which has hitherto been seen only as a gas, is in reality the gas or vapour of a very volatile metal. At all temperatures above 600°, the vapour of mercury, and at a white heat those of arsenic, zinc, cadmium, potassium, and sodium, are gases, just as hydrogen is at ordinary temperatures.

We shall commence with oxygen gas, beyond all question the most important element, and consider after it those which stand nearest to it. But, in consequence of the extreme importance for the understanding of what is to follow, and also in a practical sense of hydrogen and of nitrogen—which last has no well-marked place of its own—we shall interpolate these elements between oxygen and chlorine. After chlorine will come bromine, iodine, fluorine—the last placed here from the perfect analogy between its compounds and those of the three preceding elements; and after them, because its exact place is uncertain, since we are not acquainted with it in an uncombined state. This is the group of the negative, that is, highly negative, non-metallic ele-

ments, or supporters of combustion, with the addition of hydrogen and nitrogen.

The next group is that of the less negative or more positive non-metallic bodies, namely, carbon, sulphur, selenium, phosphorus, boron, and silicon. These elements are also called the combustible non-metallic bodies or metalloids. The non-metallic elements are 13 in number, but it seems probable that silicon will prove to be metallic, since, according to very recent statements, it has been deposited on metallic surfaces with a high metallic lustre. This, however, requires confirmation. If it prove true, silicon will then be called silicium.

The metalloids or non-metallic elements are bad conductors or non-conductors of heat and of electricity, and are destitute of the metallic lustre. At least, none of them combine the two properties of conducting power and metallic lustre. Selenium has a lustre approaching the metallic, and so has iodine, while carbon in one state conducts electricity well.

The metals, on the other hand, all possess both these characters; they are excellent conductors of heat and electricity, and they are distinguished by the metallic lustre when in a compact state, although in the state of powder or that of a spongy mass they may not exhibit this character. It will always appear, however, on burnishing, even in dull metallic powder.

We shall begin the study of the metals with the most highly positive, or those at the opposite end of the scale from oxygen, and proceed regularly to the more negative or less positive metals. We begin, then, among the metals, with potassium and sodium, pass on through lithium, which, with the two first, form the group of the alkaline metals, or metals of the alkalies proper, to those of the alkaline earths, barium, strontium, calcium, and magnesium; thence to those of the earths proper, aluminum, zirconium, yttrium, glucinium, thorinum. The next group is that of those of the heavy or common metals, which form very strong bases with oxygen, iron, manganese, zinc, cadmium, cobalt, nickel, and tin. The next contains such metals as are remarkable for forming acids with oxygen, arsenic, antimony, chromium, vanadium, molybdenum, tungsten, titanium, columbium. The next consists of metals having a less powerful attraction for oxygen, yet still forming bases with it, as bismuth, copper, lead, mercury. And the last group contains the noble metals, or those which have the feeblest attraction for oxygen, such as silver, gold, platinum, iridium, palladium, rhodium, ruthenium, osmium. There are a few metals which have not been mentioned in this enumeration, because they are not as yet known in a state of purity, and therefore their precise place is not quite fixed. Cerium, lantanium, didymium, erbium, and terbium seem to have their place between the third and fourth groups, but nearer the third if not within it. Pelopium and niobium belong apparently to the fifth or acidifiable metals. But the whole of these imperfectly known metals are of so little importance, being very rare, and as yet applicable to no purpose, that we shall do no more than indicate their existence.

Such is the arrangement we propose to follow. It will be found to a great extent natural, for most of the groups are strongly marked by nature, and indeed interesting from the extreme analogy between their constituent members.

When we have described the two first elements, oxygen and hydrogen, we shall then proceed, before taking up a third, to give an account of the compounds formed by the two first; when the third element, nitrogen, has been reviewed, we shall mention its compounds, first with oxygen, then with hydrogen; and, in short, under every element we shall describe its compounds with those previously considered. By this means we shall very soon become acquainted with the most important compounds, and thus acquire a much more extensive knowledge of chemistry in a short time than we could in a far longer period, if we described all the elements first, before speaking of any compounds, which would be a more strict and regular plan.

Our limited space compels us to be brief, so that we shall only notice essential and practically important points, and allude shortly to the technical applications of the bodies described. It will be impossible to enter into any detail as to the processes by which these substances are prepared. For these the reader must consult larger works.

NON-METALLIC ELEMENTS, OR METALLOIDS.

(A.) NEGATIVE, OR SUPPORTERS OF COMBUSTION.

1. *Oxygen.*

Symbol O. Equivalent = 8.

Oxygen is the most abundant and the most important of all the elements. It constitutes $\frac{1}{5}$th of the atmosphere, $\frac{8}{9}$ths of all the water in our globe, and fully $\frac{1}{2}$d of alumina and silica, $\frac{1}{3}$d of lime, and $\frac{1}{5}$th of potash; these being the chief ingredients of all the rocks in the earth's crust, and of the soils on its surface. It also forms a part of all the other ingredients of rocks, such as magnesia, oxide of iron, and carbonic acid, and of all abundant minerals, except only rock salt, and the sulphurets of a few metals. It is, moreover, an essential component part of all organized beings, of all tissues, and of all but a very few products of vegetable life. The quantity of it in our earth is prodigious beyond all conception, and its presence in the atmosphere is indispensable to animal life.

In its purest state, it is only known to us as a gas, which cannot be condensed into the liquid state by the most intense cold combined with the highest pressure that we can apply to it; that is, its boiling and melting points are beyond the reach of our appliances.

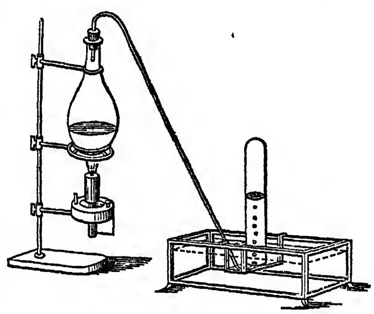

Fig. 1.

Oxygen gas is best obtained by applying heat to the chlorate of potash, a salt which yields, when heated, the whole of its oxygen, as is shown in the following equation:—

Chlorate of Potash.		Chloride of Potassium.		Oxygen.
KO, ClO_5	=	KCl	+	O_6

It is also obtained by heating peroxide of manganese, which loses part of its oxygen, and is reduced to sesquioxide. Thus:—

Peroxide of Manganese.		Sesquioxide of Manganese.		Oxygen.
$2\ MnO_2$	=	Mn_2O_3	+	O

Oxygen may be obtained by several other processes, which we have not space to mention.

It is collected over water, which has hardly any action on it. It is a transparent, colourless, tasteless, and inodorous gas. It is distinguished from other gases by its power of supporting combustion. Any burning body introduced into it burns with increased intensity and brilliancy. A candle, or a stick, or a string, with the smallest spark on it, bursts out into flame in this gas. Nay, a candle just blown out, and without even a spark, if introduced, while the wick is yet warm, into oxygen, bursts into a brilliant white flame in a short time.

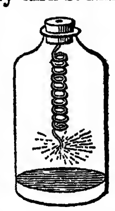

Fig. 2.

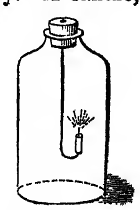

Fig. 3.

Sulphur and charcoal burn very brightly in it; phos

phorus gives out a splendid white light of dazzling intensity; and even iron, if heated to redness in it, burns with bright sparks, especially in the form of steel, as a watch-spring. Many other metals may be burned in oxygen. In short, it combines with most of the elements, with the phenomenon of combustion, or evolution of heat and light, to be presently explained.

Oxygen gas is a little heavier than atmospherical air; that is, if a given bulk of air, at a certain temperature, and under a certain pressure, weigh 1000 parts (grains, ounces, or pounds), an equal volume of oxygen gas, at the same temperature and pressure, will weigh 1111 parts. According to some, this number is a little too high, the true number being 1102·6. But the first number is very near the truth, and it is easily remembered. The number 1111 is said to represent the specific gravity or density of the gas, compared to air as a standard, 1000 being the number adopted as the specific gravity of air. The reader will understand that specific gravity or density means the relative weights of equal volumes, and is always, therefore, a relative, not an absolute property. For gases, air is made the standard of density; for liquids and solids, water.

An animal confined in oxygen at first feels little inconvenience; but after a time it appears to stimulate too powerfully, and would ultimately cause death, although it is not, like some gases, irrespirable.

Oxygen enters into combination with all the other elements, except only fluorine, which has not yet been made to combine with oxygen. The compounds of oxygen are of very great importance, as has been already stated in various places. Many compounds of oxygen, especially such as contain three or more, and occasionally two eqs. of oxygen for one eq. of the other elements, possess acid properties; and it was formerly supposed that every acid must contain oxygen, and that oxygen was the cause of acidity. But we are now acquainted with a large number of acids containing no oxygen; and if any element can be said to be the cause of acidity, it is rather hydrogen, which is found in many acids without oxygen, and in most of those which contain oxygen. But, in truth, acidity is a property belonging to the compounds, and not derived in any peculiar manner from either oxygen or hydrogen, both of which form many compounds which are not only not acid, but basic or alkaline; so much so, that all protoxides of metals are powerful bases, and neutralize acids.

The uses of oxygen are most important. Diluted with nitrogen in the atmosphere, it becomes not only respirable by animals, but indispensable to their existence. It is also essential to all such processes of combustion as are carried on in atmospherical air, and therefore assists in producing artificial heat and light. It is also a necessary agent in the important process of the decay of dead vegetable and animal matter, that process by which these are not only prevented from accumulating and proving injurious, but are at the same time converted by oxidation into those compounds which form the food of a new generation of plants. In fact, decay is a slow combustion, without the evolution of light, and with a very slow and hardly sensible development of heat.

It was at one time believed that oxygen was indispensable to every combustion; that every combustion was an oxidation. But it is now seen that it is only in such combustions as occur in our atmosphere or in pure oxygen that oxygen is essential. There are many combustions in which oxygen has no share. Thus phosphorus, antimony, and most of the metals in a state of fine division, take fire spontaneously, and burn in chlorine gas, or in the vapour of bromine or of iodine. Many metals, when heated, burn in the vapour of sulphur; but, as all ordinary and useful combustions take place in air and depend on oxygen, the term combustion is still commonly applied to those cases in which oxygen is concerned. The strict definition of the term, however, is this, chemical combination, attended by the evolution of heat and light.

In reference to combustion, oxygen is often called the supporter of combustion, and the bodies which burn in it or in air are called combustible. In like manner, chlorine and its congeners are also called supporters of combustion; but, if we reflect on the definition of combustion just given, we shall see that the two combining bodies are equally supporters of the combustion, and equally combustible. The common language is founded on the fact, that the heat and light appear to proceed from the so-called combustible (such as a candle) in the air or oxygen. But this is an illusion, depending on the fact that one of the two bodies (the air or oxygen) is a gas; and the other—whether solid, liquid, or gaseous—is placed in the middle of it, and surrounded by it. In these circumstances, combustion can only take place where the two bodies meet, which is only at the surface of the central body or combustible, whether it be a coal, or oil, or a jet of gas. If we reverse the conditions, and cause, for example, a jet of oxygen to escape into an atmosphere of coal gas, and apply a light to it, the oxygen appears to take fire, as the coal-gas did in air, and continues to burn, the heat and light appearing at the surface of the jet of oxygen, because there only action can take place. In this form of experiment we might call oxygen the combustible, and coal-gas the supporter of combustion. But, as before stated, both bodies are alike supporters of the combustion, and both alike combustible, and the appearances depend on the arrangement of the experiment. In all ordinary cases, oxygen *appears* to be the supporter of combustion, and the other body the combustible, so that practically these terms are so applied without leading to misconception.

The binary compounds of oxygen with the other elements are generally very important, and are of three kinds; 1*st*, Acid, as sulphuric, nitric, and chromic acids; 2*d*, Alkaline or basic, as the protoxides of potassium, sodium, calcium, iron, lead, silver, &c., and sesquioxides, such as those of aluminum, iron, chromium; 3*d*, Neutral bodies, that is, neither acid nor basic, but sometimes playing the part of one or the other; as water, deutoxide of manganese, deutoxide of lead. The nomenclature of all oxides has been already explained.

The acid oxides are negative compared with the basic oxides, which are positive. Hence they tend to combine together, and when such a ternary compound is decomposed by the electric current, the acid always appears at the positive, the base at the negative pole. Such compounds of a negative with a positive oxide are saline bodies, although when they are insoluble in water the usual saline characters are not seen. Examples, sulphate of potash, KO, SO_3; nitrate of soda, NaO, NO_5; these and many others have all the characters of salts. Sulphate of baryta, BaO, SO_3; carbonate of lime, CaO, CO_2; these are insoluble, but yet are true salts.

These ternary saline compounds of oxygen are undoubtedly formed when the acid and the base meet. Thus KO and SO_3 form KO, SO_3, sulphate of potash. But we do not know that in these salts the base and acid continue to exist as such; and it is now considered probable that they do not, but that the acid and base, in forming the salt, undergo a change, whereby the metal of the base forms one constituent, and all the other elements together, that is, the acid + the oxygen of the base form the other. It is only a question of the arrangement of the elements which are certainly present, for nothing is added, and nothing taken away. The old view is expressed in the formula KO, SO_3, for sulphate of potash. The new one, which is exactly equal to it, is expressed by K, SO_4, and the group SO_4 is supposed to form a compound radical, analogous in properties to chlorine, and like it forming salts by combining with metals. We shall return to this question when treating of acids, such as hydrochloric acid or sulphuric acid. Mean-

time, the reader should render himself familiar with both views of the salts which contain oxygen.

We now, for the reasons formerly given, deviate from the strictly natural order, and proceed to describe hydrogen, as being, next to oxygen, perhaps the most important of the elements, especially with regard to its compounds.

2. *Hydrogen.*

Symbol H. Equivalent = 1.

This element is, like oxygen, very abundant in nature, but almost invariably in some form of combination. It is said to occur uncombined among the gaseous products of volcanoes, which is not improbable. But it is chiefly found in union with oxygen, in water, of which it constitutes $\frac{1}{9}$th part by weight. As the quantity of water in the sea, rivers, lakes, marshes, and streams, in the atmosphere, suspended as vapour, or separating in the form of clouds, rain, snow, hail, and dew, is prodigiously great; the actual amount of hydrogen is very large. Besides the sources of water just mentioned, all animals and vegetables contain from $\frac{1}{2}$ to $\frac{3}{4}$ths of their weight of water; and hydrogen is also an essential constituent of the animal and vegetable tissues, and of all animal and vegetable products, more especially of all such as are oily or resinous, and of such bodies as wood, starch, sugar, gum, and the vegetable acids and bases of alcohol, ether, and similar compounds; of coal, bitumen, asphalt, petroleum, and fire-damp, the explosive gas of coal mines, in the mineral kingdom.

Hydrogen is easily prepared by the action of zinc or iron filings, or clippings, in diluted sulphuric and hydrochloric acids. The change is represented in the following equations.

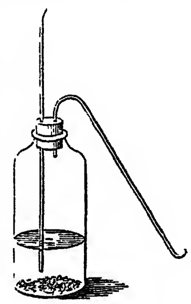

Fig. 4.

Zinc.		Sulphuric Acid.		Sulphate of Zinc.		Hydrogen.
Zn	+	HO, SO_3	=	ZnO, SO_3	+	H

and

Zinc.		Hydrochloric Acid.		Chloride of Zinc.		Hydrogen.
Zn	+	H Cl	=	Zn Cl	+	H

It will be seen, that in both cases the metal (and iron acts precisely as zinc does) takes the place of the hydrogen, which is set free. The sulphate of zinc and chloride of zinc formed are salts as analogous to each other as the acids were. The two processes are therefore in fact the same; but yet the equations differ. This depends on the view taken of the constitution of sulphuric acid or oil of vitriol, which in the first equation is represented as composed of water and dry acid. But if we take the newer view of the constitution of the acid, and consider it as a compound of hydrogen with the hypothetical compound, radical SO_4, if we represent it by H, SO_4, instead of the equivalent formula **HO, SO_3**, then the two equations become as like each other as the two operations are. Thus—

Zinc.		Sulphuric Acid.		Sulphate of Zinc.		Hydrogen.
Zn	+	H, SO_4	=	ZnO, SO_4	+	

The only difference now is, that in one case the zinc and hydrogen are united to a simple radical, chlorine, in the other to the compound radical SO_4. But it must be remembered that chlorine is only called simple or elementary because we cannot prove it to be compound, not because we know absolutely that it is simple. Indeed, it is considered probable that chlorine will one day prove to be a compound; and, in that case, the two equations would be exactly of the same kind. As it is, if we use the newer expression for sulphuric acid and sulphate of zinc, the analogy in all essential points is complete. Both acids are compounds of hydrogen, and both the salts formed are compounds of the metal with the radicals Cl and **SO_4**. The fact, that while the older view of sulphuric acid (which regards it as a compound of water with dry acid) represents these two similar processes by different equations, the newer view gives them the same form; is a very strong argument in favour of the latter, according to which sulphuric acid, and all acids which, like it, contain hydrogen along with oxygen, are compounds of hydrogen and of water, like hydrochloric acid and all acids analogous to it, of whose constitution only one view is possible. What used to be two series of acids are thus reduced to one series, and the salts of both may be regarded as forming part of the same series as their respective acids, if we define acids and salts under the name of saline compounds as formed of hydrogen and metals (which have many points of analogy) with radicals, whether simple or compound.

Let R stand for any radical capable of forming an acid and salts, any salt-forming radical; and let X represent any metal or hydrogen; then the general formula of all such acids as sulphuric and hydrochloric acids, and all such salts as sulphates and chlorides—that is to say, such acids as nitric, phosphoric, selenic, silicic acids, &c., as well as hydrobromic hydriodic, hydrofluoric, hydrosulphuric acids, &c., and the nitrates, phosphates, seleniates, silicates, &c.—and the bromides, iodides, fluorides, and sulphurets, &c.—the universal formula for all such compounds is X R.

For X we may substitute the symbol of any metal, or of hydrogen; and for R, that of any salt forming radical, simple, or compound; and thus we obtain such special cases of the general formula, as H Cl; HF; HS; H, SO_4; H, NO_6; H, PO_6; KCl; NaBr; CaF; PbS; Ba, SO_4; Ag, NO_6; &c. The reader, by referring to the table of symbols, will easily discover what are the elements whose symbols are used, and will see that the series of which the general formula, as above explained, is X R, includes a very large number of acids and of salts, perfectly analogous in properties, which were formerly, and even still are, placed in two different series.

We have taken the opportunity of the process for making hydrogen to explain the principle on which this great simplification is effected, and so large a number of compounds of hydrogen, namely, all the important acids, are classed together, instead of separately. The reader will find frequent occasion to avail himself of what has now been explained.

To return to hydrogen. When prepared as above explained, it appears as a gas, and is collected over water. Like oxygen, it is known only in the form of gas, never having been yet liquefied by the most intense cold and pressure. When pure it is colourless, tasteless, and inodorous, but when prepared from zinc, and especially from iron, it has a peculiar smell, arising from the presence of an oil formed by impurities in the metals. Hydrogen prepared from water by the electric current has no smell. It is the lightest body known, its specific gravity being 69·4 compared to air as 1000. It is exactly 16 times lighter than oxygen.

A burning body introduced into hydrogen is extinguished for want of oxygen; but the hydrogen, being heated by the flame, and in contact with the oxygen of the air at the mouth of the vessel, takes fire and burns away very rapidly from its lightness, if the mouth of the vessel be upwards; and very slowly, for the same reason, when the mouth of the jar is turned downwards, which prevents it from readily mixing with the air. The flame of burning hydrogen is very feebly luminous, but intensely hot, that is, much heat and little light are evolved in its combination with oxygen. When hydrogen is mixed with oxygen, or even with air, and a light applied, explosion ensues, and both gases disappear, water being the only product. The mixed gases are also exploded by the electric spark, and by contact with platinum, in the form of sponge or of powder, as we shall see presently.

Hydrogen is highly positive, and has a very strong affinity for oxygen, with which it forms at least two compounds, water, HO, and deutoxide of hydrogen, HO_2; and

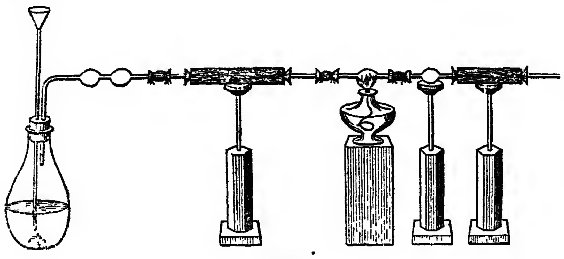

Fig. 5.

probably a third, a teroxide or peroxide, HO_3, if recent statements to that effect shall be confirmed. By reason of this attraction for oxygen, hydrogen is much used by chemists as a deoxidizing agent, especially when aided by a red or white heat. When the gas is passed through a red-hot tube containing the oxide to be reduced, water is formed, and the substance which was combined with oxygen is left in a state of purity.

It has also been used from its lightness for filling balloons; and a balloon of very moderate size filled with hydrogen has a great ascending power. But coal-gas is so much cheaper, and, although heavier than hydrogen, yet with a large balloon has so much ascending power, that it has supplanted hydrogen for this purpose.

It is used also, when burned in a jet with oxygen, which gives what is called the oxy-hydrogen blow-pipe, to produce the most intense heat that is known, except perhaps that of a powerful galvanic battery, and that of the sun's rays collected in the focus of a large burning-glass. This will be explained in treating of the combination of oxygen and hydrogen.

Lastly, hydrogen is made, in this country, the standard or unity of equivalent or atomic weights; for which purpose it is well adapted as having by far the lowest equivalent among the elements.

Hydrogen with Oxygen.

(1.) *Water* $HO = 9$.

We have already mentioned the various circumstances which cause these two gases to combine. If mixed and kept at the ordinary temperature, or in any heat short of a strong red heat, they have no action on each other. But the contact of flame, or of any other red-hot body, the passage of the electric spark, which is intensely hot, and the contact of platinum, cause the combination to take place with explosion. The flame and the electric spark act by their intense heat; but the action of platinum is more obscure. Spongy platinum, and the fine powder of that metal called platinum black, although cold, cause the mixed gases to explode as readily as flame does. Even polished slips of platinum, if perfectly clean, will cause them to combine, though more slowly; and it is then seen that the contact of the cold metal first causes a part of the gases to unite; this produces warmth; the metal being warmed by it, acts more vigorously; more heat is developed, so that by degrees the metal becomes red-hot, and if any of the mixed gases be still uncombined, it causes them to explode. In the case of the powder or the sponge, especially the former, all this takes place so rapidly from the enormous surface of the metal, that it becomes red-hot as soon as it is introduced, and fires the mixture as rapidly as a flame.

But all this does not explain how the platinum causes the gases to combine at first. There are two views on this point, both suggestions, and neither established. One supposes that the surface of the metal attracts the particles of both gases, because there is not the same repulsion between a solid and a gas as between two gases, or the particles of the same gas; that consequently the particles of the two gases come on the surface of the metal nearer to each other than elsewhere, and near enough for affinity to act. According to the other view, proposed by Doebereiner, the pores of the spongy or powdery metal are filled with oxygen absorbed from the air, and condensed with so great a force as to occupy only $\frac{1}{800}$th part of its former bulk. This condensation he ascribes to a peculiar molecular attraction; and he states, that the powder when heated gives off a large amount of oxygen, although there is certainly no combination between the metal and any part of the oxygen. As this condensed oxygen is denser than if it were liquid, although still gaseous, its particles come near enough to those of the hydrogen to combine with them. Either explanation, if true, still leaves unexplained how the platinum attracts the gases, or condenses the oxygen. Doebereiner constructed a lamp for instantaneous light on this principle. It is very ingenious, but the spongy platinum is apt to lose its efficacy, from the vapours of various substances adhering to it. Other metals, and even other porous bodies, exhibit the same property, though in an inferior degree, and usually only when aided by heat.

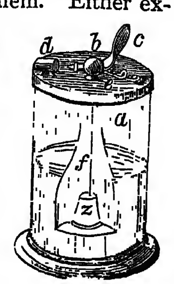

Fig. 6.

When oxygen and hydrogen, from whatever cause, combine, either by combustion or explosion, it is always in the proportions to form water; that is, invariably 2 volumes of hydrogen gas to 1 volume of oxygen gas. Any excess of

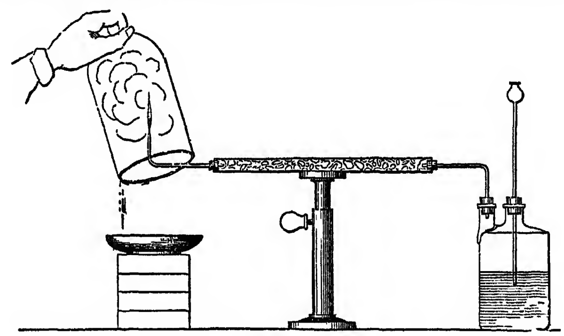

Fig. 7.

either is left uncombined. As the two gases both disappear, it is plain that, if we measure the volume that has disappeared, that is, the contraction in volume, by comparing the residue with the original volume, ⅔ds of that loss of volume must be hydrogen and ⅓d oxygen. This enables us to use hydrogen to determine the amount of free oxygen in air, or in any gaseous mixture, as will be explained under atmospheric air.

The composition of water has been proved in many different ways, both synthetically and analytically. It is a point of great importance with reference to the analysis of other bodies.

Synthetically, oxygen and hydrogen, carefully measured, are made to burn together in a jet, and the water produced is collected and weighed. The weight of the gases consumed is known from their volume and densities, and that of the water is exactly their sum. 8 lb. of oxygen and 1 lb. of hydrogen yield 9 lb. of water. $O + H = HO$.

Or hydrogen gas is passed over a weighed portion of oxide of copper in a tube heated to redness. (See Fig. 5.) The oxygen of the oxide combines with hydrogen, forming water, which is carried onward by the current of gas into a small weighed apparatus containing chloride of calcium, which retains all the water. The increase of weight in this

vessel gives the amount of water formed; the loss of weight in that containing the oxide of copper now reduced to a metal, gives the amount of oxygen, and the difference is the hydrogen. 39·7 grains of oxide of copper yield 9 grains of water, and 31·7 of metallic copper. The loss, 8 grains, is oxygen, and the difference, 1 grain, is hydrogen. The equation is $CuO + H = HO + Cu$.

Analytically, the composition of water is proved by passing a weighed quantity of its vapour over a red-hot metal, such as iron, excluding air. The increase of weight in the metal, which is oxidized at the expense of the water, gives the oxygen, and the difference is hydrogen; or the

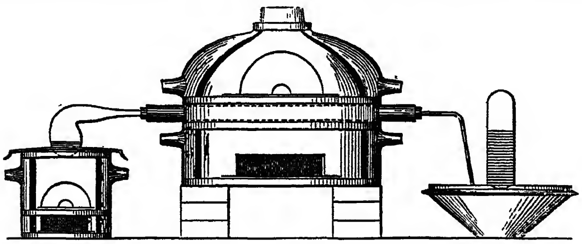

Fig. 8.

hydrogen may be collected and measured or weighed. This process, however, is difficult, and only used as an illustration. Potassium placed in contact with water, under the surface is oxidized, disengaging hydrogen, which may be collected, the oxide dissolves in the remaining water, and this may be evaporated, and the amount of potash determined in the form of a salt, such as the sulphate.

Or, water may be decomposed by the electric current, and the two gases separately collected and measured. They are invariably in the proportion of 2 volumes of hydrogen to 1 of oxygen, and as oxygen is 16 times heavier than hydrogen, 1 volume of oxygen must weigh 8 times as much as 2 volumes of hydrogen.

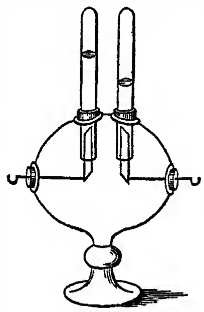

Fig. 9.

In these different ways the composition of water has been proved. Its formula is HO, at least in this country. On the Continent, where atoms and volumes are believed to agree, the formula of water is H_2O. This is merely a question of what is the weight of 1 atom of hydrogen. We consider that 1 atom of hydrogen weighs the eighth part of 1 atom of oxygen. The French chemists say that it weighs only $\frac{1}{16}$ of 1 atom of oxygen, so that 2 atoms are required to yield the proportion of 1 to 8. The same remark applies to the volume. We consider the atom of hydrogen as represented by twice the volume of 1 atom of oxygen; they regard 1 atom of hydrogen as having the same volume as 1 atom of oxygen. But they agree with us as to the equivalent, for they regard the equivalent of hydrogen, in water, as formed of 2 atoms.

The properties of water are well known. It is of all compounds the most important, being essential to both animal and vegetable life. It has neither colour, taste, nor smell, melts at 32° Fahr., and boils at 212° Fahr. It is therefore solid at all temperatures below 32°, and gaseous at all above 212°.

It has a remarkable power of dissolving solid matters, and on this its use chiefly depends.

Water is the standard of specific gravity for liquid and solid bodies, and its specific gravity is made 1, 10, 100, or 1000, according to the writer's choice.

It is remarkable that the point of greatest density in water is not, as might be expected, about 33°, when it is about to freeze, but about 39°·5, and it becomes lighter both above and below that degree of heat. This has a most important practical effect, for when deep water is cooled by frost, the water keeps sinking as it cools till its temperature falls below 39°·5 when it becomes lighter, and remains at the surface till frozen, and then it is lighter still. From that point, therefore, there is no further mixture of the colder with the warmer water, and below the crust of ice and the upper stratum of water, there remains a mass of water at 39°·5, which is only cooled very slowly by conduction. This is one reason why deep lakes are never entirely frozen, and why in the hardest winters the ice never extends far from the surface. Were it otherwise, the freezing would begin at the bottom, the whole mass, however deep, would soon be frozen, and the summer might not suffice to melt it all again.

There is another reason why freezing and melting are slow operations. When a body melts, a large amount of heat disappears or becomes latent, and is employed in giving the liquid form to the solid body, without raising its temperature above the melting point till all is melted. In congelation again, this latent heat reappears and prevents the temperature from falling below the freezing point, however intense the cold applied, till the whole is frozen. For these reasons, the freezing of large masses of water, and the melting of large masses of ice, are both very slow operations.

The same thing occurs when water is boiled or converted into vapour. This takes place at 212°; but so great is the amount of heat that disappears in forming steam, that if a vessel of water be placed on white-hot coals, the water will boil away slowly, but will never rise above 212°, while any water retains the liquid form. And, in like manner, when steam is condensed by cold, all this heat becomes sensible and keeps up the temperature at 212°, whatever cold be applied, till the vapour is entirely liquefied, when the temperature begins at once to fall.

A familiar proof of the enormous amount of latent heat in steam is obtained in the fact, that boiling water at 212°, and steam at 212°, produce totally different effects on the skin. The scald from steam is very greatly more severe than that from boiling water at the same temperature. Again, if we add 4 oz. of boiling water to 16 oz. of water at 60°, the mixture is barely tepid; but if we force 4 oz. of steam at 212° into 16 oz. of water at 60°, the whole 20 oz. will be found to boil briskly. Hence the use of steam as a heating agent, which has the advantage that it cannot heat any substance in open vessels beyond 212°, and cannot therefore char or injure them.

Besides boiling at 212°, under the ordinary atmospheric pressure, water is slowly converted into vapour, or it evaporates at all temperatures. In this way water rises into the air from the sea, lakes, rivers, &c., and falls again as rain, snow, and dew. Some heat is required for evaporation as well as for boiling; the necessary heat is taken from the surrounding bodies, and cold is the result. Water, at a temperature not very far above the freezing point, is so much cooled by its own evaporation, that part of it is frozen by the evaporation of the rest. Ice is actually thus obtained on cool nights in hot climates. The same result is obtained at ordinary temperatures, if the pressure be diminished, which accelerates evaporation. This is well illustrated by Wollaston's cryophorus.

Under diminished pressure water boils at temperatures below 212°. For this reason it boils lower on the top of a mountain than at its base. 212° is the boiling point of water at the sea level, under the average pressure, or with the barometer at or near 29 to 30 inches. In ascending mountains, the boiling point falls 1° Fahr. for every 440 feet of ascent. The height of mountains may be thus pretty accurately measured, provided the state of the barometer be noted below, at the level of the sea, as well as on the hill top.

Under increased pressure, as when the steam is not allowed to escape freely, water boils at temperatures above

212°, and higher, in proportion as the pressure is higher; as is well shewn by Dr Marcet's machine. This occurs in the high-pressure steam engine, in which the steam cannot escape till its elasticity is so far increased by heat, as to overcome the pressure on the piston or on the safety-valve. When such increased pressure is suddenly taken off, by allowing the steam to escape, while the temperature is far above 212°, the steam rushes out with great force, and the temperature within rapidly sinks to 212°. This is the principle of the high-pressure engine; while in the low-pressure form, the steam is simply allowed to enter the cylinder below the piston, and after it has forced up the piston-rod, is condensed by a jet of cold water, steam being at the same moment admitted above the piston, and so on alternately. For full details on these matters the reader must refer to works on mechanics and on the steam engine.

Water, when frozen, increases in volume to a considerable extent, so that ice is lighter than water, and floats on its surface. This expansion takes place with irresistible force; and hence the freezing of small portions of water which has filled the spaces between the layers of the hardest rocks, bursts them asunder. For this reason hard frost is perhaps the most powerful agent in the disintegration of rocks.

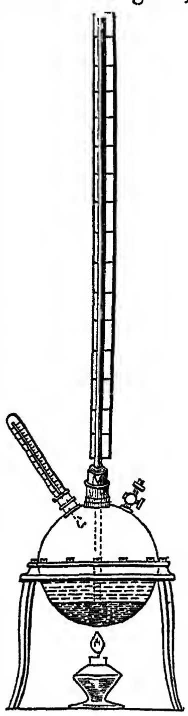

Fig. 10

The chemical characters of water are very important. It combines with dry or anhydrous acids, producing the hydrated acids, which, as has been explained, may be viewed also as hydrogen acids. Thus hydrated sulphuric acid may be represented either as HO, SO_3 or H, SO_4. Water combines also with anhydrous bases, forming hydrates of the bases. Thus anhydrous lime, CaO, combines with water, forming hydrate of lime or slaked lime, CaO, HO. Thirdly, water combines with neutral salts, forming hydrates. Thus sulphate of magnesia, MgO, SO_3 combines with 1 eq. of water to form the hydrated salt, MgO, SO_3, HO. Lastly, water combines with salts, both anhydrous and hydrated, in another form, which is called water of crystallization. The hydrated sulphate of magnesia, MgO, SO_3, HO, takes up 5 eqs. more of water to form the usual crystallized salt, which is represented as follows, $MgO, SO_3, HO + 5$ aq. It is easily shown that these 5 eqs. are in a different state of combination from the first eq.; for a gentle heat expels the five, but a red heat is required to expel the sixth. Again, this equivalent of water may be replaced by a neutral salt or by sulphate of potash, yielding the double salt, $MgO, SO_3 + KO, SO_3$, which cannot be done with the five others. Here we see that water plays the part of a neutral salt; whereas in hydrated acids it plays that of a base, and in hydrated bases that of an acid; being replaceable in the former case by bases, in the latter by acids, and, as we have seen, in the case of its combining with neutral salts, by neutral salts.

But there is a fourth form in which water combines with other bodies, that, namely, in which it dissolves them. Here we have not the same distinct evidence of its combining in definite proportions; inasmuch as, although there be a limit to the quantity of any solid substance water can dissolve, there is none to the quantity of water that may be made to combine with a given weight of any such body. In other words, aqueous solutions may be diluted to any extent. It is probable that water forms with each substance certain definite liquid compounds, characterized by their special densities, boiling points, &c.; and that these are miscible in any proportion. Professor Graham, who has already investigated the diffusion of gases, has long been engaged in profound researches on the mutual diffusion of aqueous solutions. He has obtained very interesting results; but our space forbids our entering on these, especially as the investigation is still in progress.

Heat, as a general rule, increases the solvent power of water, while cold diminishes it. There are a few exceptions. Thus common salt is not materially more soluble in hot than in cold water; and hydrate of lime is less soluble in hot water than in cold. In general we can obtain crystals of substances soluble in water by boiling them with that fluid till it is saturated, when, on cooling, as its solvent power diminishes, it deposits in crystals what it cannot retain in solution. Crystals are also obtained by the slow or spontaneous evaporation of aqueous solutions. Some substances crystallize best in the one method, some in the other.

In consequence of its great solvent power, water is never found pure in nature. Even rain-water dissolves gases, and minute portions of solid matters which it meets with in falling through the atmosphere. We can always detect ammonia, carbonic acid, and sea-salt in rain-water, even when collected in clean vessels at a distance from towns. The salt is no doubt carried into the air from the sea by high winds, and is therefore more abundant during or immediately after a strong gale blowing from the sea. As soon as rain reaches the earth, it begins to dissolve a part of almost everything it meets with in the rocks or soil through which it filters, such as sea-salt, gypsum, silicate of potash, carbonate of lime (in virtue of the carbonic acid already in the rain-water, as well as of that it takes up from the soil), carbonate of magnesia, carbonate of iron, compounds of iodine or bromine, if present; also fluoride of calcium, phosphate of lime (soluble in solution of carbonic acid), and organic matters. According to the amount of dissolved matter, which varies exceedingly, spring and river water is hard or soft, or becomes mineral water. When the solid matter dissolved does not exceed from 1 to 6 or 8 grains per gallon, the water is soft, especially if the proportion of supercarbonate of lime be small. But when more solid matter is present, especially supercarbonate of lime and gypsum, when there are from 10 to 15, 20, 30, 50, 80, 100, or even, as sometimes happens, 150 grains of solid matter in a gallon, the water is more or less hard, the salts of lime decomposing soap, and rendering necessary a large consumption of it to obtain detergent effects. Moreover, the supercarbonate of lime is decomposed on standing, or when boiled, and deposits a crust of neutral carbonate of lime, which renders hard water totally unfit for use in steam boilers, and in fact ruinous to the boilers by the effects of the crust, to the presence of which many explosions have been justly referred. The methods of detecting the presence of these impurities, and of improving the quality of hard water, will be mentioned under the head of the substances named.

When the amount of foreign matter exceeds a certain proportion, and especially if it consist of salts of soda and magnesia, of iron, of sulphurets of metals, or of sulphuretted hydrogen, of alkalies, or of carbonic acid, the water is called a mineral water, although all water is mineral. Sea-water is a true mineral water. Such as are charged with carbonic acid are called acidulous or sparkling waters; such as contain saline matters are saline waters; those containing sulphur, iron, or alkalies, are respectively sulphureous, chalybeate, or alkaline waters.

Pure water can only be had by distillation; and even in distilled water there are often traces of ammonia and carbonic acid.

The importance of water to man cannot be over-estimated. It is essential to both animal and vegetable life, the best soil being barren if no rain fall. It is almost equally essential to almost all chemical operations, among which vegetation may be included. It is through water that plants are supplied with their whole food, namely, carbonic acid, ammonia, silicate of potash, sulphate of lime, sea-salt, carbonates of iron, magnesia, lime; phosphates of lime and magnesia; iodides, bromides, and fluorides; the carbonates and phosphates, which are insoluble in pure water, being dissolved in water containing free carbonic acid, which also contributes powerfully to the disintegration, and to the rendering soluble of the useful constituents of felspar and of clay, which is half-decomposed felspar.

In the animal body, every part, solid or liquid, consists chiefly of water, which forms at least $\frac{3}{4}$ths of the weight of all the soft solids, and about $\frac{3}{8}$ths of that of the bones.

We shall see that, besides its use as a solvent, and as a constituent of organized tissues, water takes a share, *by its elements*, in the formation of almost all organic compounds whatever. It is certainly of all compounds the most valuable and useful.

(2.) *Deutoxide of Hydrogen*, $HO_2 = 17$.

Water can take up an additional eq. of oxygen, and is thus converted into the deutoxide. This compound is obtained, in a diluted form, by the action of hydrochloric acid on successive portions of deutoxide of barium, which sets free an eq. of the deutoxide; thus, $Ba\,O_2 + H\,Cl = Ba\,Cl + HO_2$. The deutoxide of hydrogen and the chloride of barium both dissolve in the water in which the process is carried on. Sulphuric acid, cautiously added, removes the barium as the insoluble sulphate, leaving free hydrochloric acid as before; thus, $Ba\,Cl + HO,\ SO_3 = Ba\,O,\ SO_3 + H\,Cl$. In the filtered liquid, a second portion of deutoxide of barium is dissolved, and the whole process is repeated till the liquid is sufficiently charged. It is thus concentrated by evaporation *in vacuo*, and when pure has the consistence of a thin syrup. Its preparation is a tedious and delicate process; and when made it can only be preserved in a freezing mixture for a time, as it undergoes spontaneous decomposition, and that very rapidly, at ordinary temperatures. Phosphoric acid, and even sulphuric acid, may be substituted for the hydrochloric acid.

The deutoxide of hydrogen readily parts with half its oxygen, and is reduced to water by contact with organic matters. It disorganizes the skin, causing a white spot. It gives off oxygen spontaneously, and the presence of various powders hastens the change. When oxide of silver, for example, is introduced into it, rapid effervescence ensues, and there is given off, not only the second eq. of oxygen of the deutoxide, but also the oxygen of the oxide of silver, which is thus reduced to the metallic state, or deprived of oxygen, by one of the most powerful oxidizing agents, which we should rather expect to yield oxygen to it. The explanation appears to be, that the *motion* of the particles of decomposing deutoxide is mechanically communicated to those of the oxide of silver, and the equilibrium of that compound being thus destroyed its elements separate. Several other oxides are decomposed in the same way.

The deutoxide of hydrogen has been occasionally used to oxidize certain substances in chemical research, and has been proposed as a remedy. In both ways it may probably prove useful, but the difficulty of preparing it and preserving it will, for the present, very much limit its employment.

(3.) *Ozone.*

This name has been given, on account of its pungent smell, to a substance formed under several circumstances; as when electric sparks are passed through dry oxygen gas; or better, when water is decomposed by the electric current, when it (ozone) is found in the oxygen collected at the positive pole; and, finally, when phosphorus is slowly oxidized in atmospherical air, which thus acquires the odour of ozone.

By whatever method it is formed, its quantity is always singularly small, so that it has hitherto been found impossible to obtain it pure, or to analyse it quantitatively. But its odour is very powerful, resembling that of chlorine, and also that which is observed in thunder-storms. As to its other properties, it is a most energetic oxidizing agent, and therefore contains oxygen, probably in large quantity. Its presence is easily detected either by the smell, or by its power of decomposing iodide of potassium, setting free the iodine, and of oxidizing the salts of protoxide of manganese, so as to form peroxide.

From these characters, and from its occurring where oxygen is in the nascent state, as at the positive pole of the battery, and in presence of water, it is supposed, on good grounds, to be either an isomeric (or allotropic) form of deutoxide of hydrogen, or a teroxide of hydrogen. Recent researches tend to show that there are probably two compounds included under the name ozone, and that the ozone formed in the electrolytic decomposition of water is really teroxide of hydrogen, while that formed in dry oxygen gas is an allotropic modification of oxygen gas.

It is probable, from the facility with which it is formed, and the equal facility with which it is decomposed, that ozone is very often produced in the atmosphere, and acts powerfully on other bodies. It destroys organic substances, even when diluted with much air or oxygen, so that neither cork nor caoutchouc can be used to connect the apparatus in which it is prepared. Hence it probably plays an important part in hastening the oxidation or decay of dead organic matter.

3. *Nitrogen.*

Symbol N. Equivalent = 14.

This element, like hydrogen, is here introduced out of its strict place, on account of its great importance, and especially of the importance of its compounds.

Nitrogen occurs, mixed with oxygen, in our atmosphere, of which, when dry, it constitutes about $\frac{4}{5}$ths. It is also found in all organized tissues, and in the juices of plants and animals, as an essential constituent. In the crust of the earth it occurs in certain spots, in the form of the nitrates of potash and soda, that is, compounds of these bases with nitric acid. It is also an ingredient of ammonia, which exists in the atmosphere, and is produced from volcanoes.

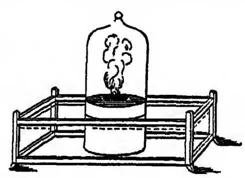

Fig. 11.

Nitrogen is best obtained from air, by removing the oxygen by means of phosphorus, which, if made to burn under a bell gas, inverted over water, combines with the oxygen, forming phosphoric acid, and this acid is dissolved by the water, leaving the nitrogen pure. It may also be obtained by the action of chlorine on a solution of ammonia.

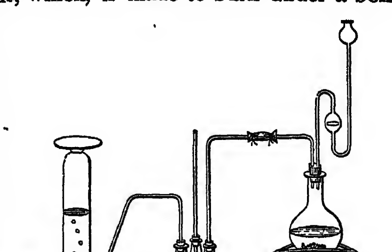

Fig. 12.

However prepared, nitrogen always appears as a transparent, colourless, tasteless, and

inodorous gas. Water absorbs only a very minute portion of it. It is rather lighter than air, in the proportion of 972·2 to 1000. This must be so, since a mixture of it with oxygen, which is rather heavier than air, has the density of air. It extinguishes the flame of any burning body, and does not take fire itself as hydrogen does. It cannot support animal life when respired, but it is not poisonous, as some gases are. Animals soon die in pure nitrogen gas, but this is simply from the want of oxygen. For at all times we breathe air, which is only a mixture of oxygen with four times its volume of nitrogen, not only without injury, but with advantage, for it serves to dilute the oxygen and render it fit for respiration. It will be seen that nitrogen is characterized entirely by negative properties.

It is one of those gases which has hitherto resisted all attempts to condense it into the liquid state.

Nitrogen has very remarkable and important chemical relations. Its affinities for oxygen and for hydrogen are both considerable, and pretty nearly equal, and it is capable of combining both with the positive and the negative elements. But its compounds, from the fact that it has affinities in every direction, and those not the strongest, are in general easily decomposed, and frequently with explosive violence. To those complex organic compounds in which it is an essential ingredient, it gives a tendency to undergo transformations of all kinds, by which they are fitted for the functions they have to perform; and it is such compounds alone that undergo the transformation called putrefaction, and another similar one, by which they become ferments, or exciters of fermentation.

Nitrogen and Oxygen.

Nitrogen forms several compounds with oxygen, which have been already alluded to as an example of multiple proportions. Besides these, there is atmospheric air, a mixture, not a compound, of these gases, which we shall consider after them.

(1.) *Protoxide of Nitrogen*, $NO = 22$.

This compound is obtained by the action of heat on nitrate of ammonia, thus:—$NH_3, HO, NO_5 = 4\,HO + 2\,NO$. Here all the hydrogen is oxidized to water, and the remaining oxygen is just sufficient to convert into protoxide the nitrogen, both of the acid and of the base.

The protoxide is, at ordinary temperatures, a gas, transparent and colourless, having a sweetish taste and faint smell; it is absorbed by water to some extent, but may be collected over that liquid, although it cannot be long kept in contact with it. It supports the combustion of burning bodies pretty much as oxygen does, evidently because it contains half its volume of that gas. It may be breathed, but cannot be thus taken for more than a short time, because its action paralyses the muscles of the mouth, which cease to grasp the tube, and common air enters. An animal confined in the gas soon dies, after exhibiting symptoms of excitement.

When respired by man, it first produces a sensation of thrilling and warmth in the chest, spreading to the extremities, followed, as we have stated, by paralysis of the muscles of the mouth, which puts a stop to the further breathing of it. Then, usually after a very short period of quiet and almost of stupor, the patient becomes excited, sings, laughs, leaps, dances, sports, and begins to indulge in violent muscular actions, to which an irresistible tendency is felt. The laughter which occurs in most cases is entirely without object, and as it excites laughter among the bystanders, the patient is apt to take offence and to threaten them. He is generally, however, good humoured, unless force be roughly applied to restrain him, when he becomes violent. In the course of a minute or two all has passed suddenly off, and the patient returns to full consciousness with a bewildered stare, having either no recollection, or a very confused one, of what he has done and felt. He usually describes his sensations as agreeable, and states that at a certain time he became unconscious or nearly so. In some cases this excitement either does not appear or is only brief and transient, passing into complete unconsciousness and apparent stupor. In this state, and frequently also in that of excitement, insensibility to pain is present, as we have often ascertained. In fact, the action of the gas, as well as its taste and the sensation it produces in the chest, are the same as those of the vapour of ether and of chloroform. The reason why it produces, in general, excitement, and rarely complete unconsciousness, is simply this; that being a gas, it must be breathed from a bag through a tube; that, by paralysing the muscles of the mouth, it puts an end to the inhalation of the gas before enough has been taken to produce full coma and anæsthesia, except in a few individuals who are more easily affected. Ether and chloroform, being volatile liquids, can be poured on a sponge or cloth, and held to the mouth and nose of the patient, so as to insure a full dose. But where by chance an insufficient dose of them is given, the stages of excitement, laughter, singing, &c., appear just as with the laughing gas. We have repeatedly produced entire coma and insensibility to pain by this gas in persons easily affected; and as we have repeatedly inhaled all three substances, we can testify to the identity of the effects, bearing in mind the impossibility, in most cases, of giving a full dose of the gas.

This gas is formed of 2 volumes of nitrogen and 1 volume of oxygen the three volumes after combination occupying the space only of two. This condensation to the amount of $\frac{1}{3}$d renders the gas a heavy one. For we have—

	1 vol. oxygen, weighing	=	1111
	1 vol. nitrogen, ...	=	972
	1 vol. nitrogen, ..	=	972
which yield	2 vols. protoxide of nitrogen, weighing		3055
Consequently	1 vol. of protoxide, weighs		1527

and this number 1527, represents its specific gravity.

By a pressure of upwards of 50 atmospheres at 32° Fahr., or by a less pressure at lower temperatures, this gas is liquefied. The condensed gas is a very mobile liquid, which, on the tube being opened, assumes the form of gas with explosive rapidity, producing intense cold by its vaporization. The most intense cold yet produced has been obtained by means of this gas *in vacuo*. It has also been solidified by the cold produced by its own evaporation.

(2.) *Deutoxide of Nitrogen*, $NO_2 = 30$.

Prepared by the action of moderately strong nitric acid on copper.

Copper.		Nitric Acid.		Nitrate of Copper.		Deutoxide of Nitrogen.
$3\,Cu$	+	$4\,NO_5$	=	$3\,(Cu\,O, NO_5)$	+	NO_2

It is a gas, transparent and colourless, not absorbed by water. It cannot be tasted, smelled, nor inhaled, on account of its action on common air, with the oxygen of which it forms red, suffocating, corrosive vapours of nitrous acid, NO_4. This character distinguishes it from all other gases.

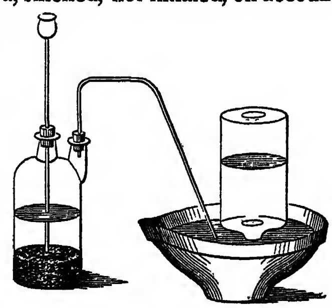

Fig. 13.

It is formed of equal volumes of oxygen and nitrogen united without condensation. Hence its specific gravity is the mean between those of oxygen and nitrogen.

	1 vol. oxygen,	weighing	1111·1
	1 vol. nitrogen,	...	972·2
yield	2 vols. deutoxide,	...	2088·3
and	1 vol,	... weighs	1041·6

It is, therefore, very little heavier than air. As it contains, like the preceding gas, half its volume of oxygen, it supports the combustion of some burning bodies, especially of phosphorus, if introduced into it in full combustion, when the phosphorus burns nearly as brightly as in oxygen.

This gas is absorbed by a solution of sulphate of protoxide of iron (green vitriol), which it turns black. The black liquid absorbs oxygen powerfully.

The attempt to inhale this gas is most dangerous, because, meeting with air in the mouth and air passages, it forms nitrous acid, which is corrosive. The gas itself appears to be poisonous.

When mixed over water with half its volume of oxygen, that is, as much as it already contains, there is instantly formed the red gas of nitrous acid, which is quickly absorbed by the water, the gases entirely disappearing. The action is $NO_2 + O_2 = NO_4$.

(3.) *Hyponitrous Acid,* $NO_3 = 38$.

Hardly known in a pure state. It seems to be a liquid, blue at ordinary temperatures, colourless at 32°, and very volatile, its vapour being red, like that of nitrous acid. When the vapour of this acid is passed through nitric acid, it gives it either a blue colour or an olive colour, according to the quantity, nitric acid being probably also formed, and its orange colour mixing with the blue, produces the olive. Hyponitrous acid forms some salts, and enters into some compounds derived from organic substances. Its vapour is obtained by heating starch with nitric acid, but is not free from nitrous acid.

(4.) *Nitrous Acid,* $NO_4 = 46$.

Obtained by mixing oxygen and deutoxide of nitrogen as already explained, or by heating nitrate of lead. The change in the latter case is—

Nitrate of Lead.		Oxide of Lead.		Oxygen.		Nitrous Acid.
$Pb\,O, NO_5$	$=$	$Pb\,O,$	$+$	O	$+$	NO_4

It is a volatile liquid, colourless when cold, straw-yellow when somewhat warmer, and orange-yellow or orange-red when warm. Its vapour is deep red. It is very corrosive. It has a remarkable action on the solar spectrum, which Sir D. Brewster has described. It forms salts, called nitrites, and in organic chemistry it is frequently substituted for its equivalent of hydrogen, producing what are called nitro-compounds, such as nitro-benzoic acid, nitraniline, and others, to be afterwards described; gun-cotton is one of these, being woody fibre, or cellulose, in which a certain amount of hydrogen has been replaced by nitrous acid.

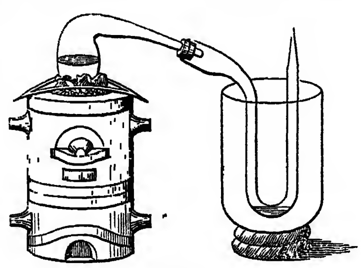

Fig. 14.

(5.) *Nitric Acid,* $NO_5 = 54$.—*Hydrated Nitric Acid,* HO, NO_5 or H, NO_6.

This acid is obtained by heating nitrate of potash with its own weight of sulphuric acid. The action is as follows:—

Nitrate of Potash.		Sulphuric Acid.		Bisulphate of Potash.		Nitric Acid.
KO, NO_5	$+$	$2\,(HO, SO_3)$	$=$	$(KO, HO, 2\,SO_3)$	$+$	HO, NO_5.

The acid collects in the receiver as a colourless fuming liquid in the middle of the process, but is coloured by a little nitrous acid at the beginning and end. When coloured, it is easily purified by redistilling, when the red vapours of nitrous acid pass off first, and the colourless acid then distils. By collecting separately the first tenth or twentieth part in the original process, all impurities adhering to the neck of the retort are washed away, and the rest is quite free from all traces of sulphuric acid or of potash.

Nitric acid, when pure, has the specific gravity 1520, compared to that of water as 1000. It is highly corrosive, and stains the skin yellow. It readily yields part of its oxygen to bodies having an attraction for it, being itself reduced to nitrous or hyponitrous acid, or to deutoxide of nitrogen. Its action on metals and on organic substances, especially oils, is very violent. It combines with bases to form salts, called nitrates, which at a red heat oxidize all oxidizable matter, often with explosion. Nitrate of potash, or nitre, is the oxidizing agent in gunpowder.

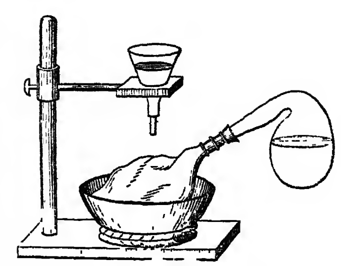

Fig. 15.

The presence of free nitric acid is detected by its power of decolorizing solution of indigo, and by its causing solutions of the salts of protoxide of iron to become nearly black; and when it is in the form of a nitrate, sulphuric acid is first added to set it free, and then the salt of iron.

Nitric acid is much used as an oxidizing agent, both in chemistry and the arts. It is employed, somewhat diluted, to corrode copper in etching. By means of nitric acid sugar and starch are converted into oxalic acid. Nitric acid is also used in medicine.

The acid we have described is the hydrated acid, and may be viewed either as composed of water and dry acid, HO, NO_5, or as formed of hydrogen, with the hypothetical radical, NO_6; thus, H, NO_6. It was long supposed that the anhydrous acid did not exist in a separate form, and that the 1 eq. of water in HO, NO_5 could not be removed. But it has recently been shown, that the dry acid NO_5 may be obtained by the action of chlorine or dry nitrate of silver; thus, $Ag\,O, NO_5 + Cl = Ag\,Cl + O + NO_5$. Anhydrous nitric acid forms crystals which are volatile and easily decomposed by heat or otherwise. But the hydrate, as in other cases, is the true active permanent acid.

Atmospherical Air.

Our atmosphere, as already mentioned, consists chiefly of nitrogen and oxygen gases. But these, although present in atomic proportion, or very nearly so (for their proportion is very close to N_2O) are not combined, but only mixed together. This is proved by the fact that air has no new properties, but only those of oxygen diluted by nitrogen, and also by this, that a mixture of the two gases, in due proportion, is found to have all the properties of air. The circumstance that two gases of different densities are found uniformly mixed, is explained by the diffusion of gases. When two vessels, one full of carbonic acid gas, the other of hydrogen, gases which *do not combine*, are made to communicate by a tube, the hydrogen being uppermost, they are found in a very short time equally and uniformly mixed, although the lower gas is more than 20 times heavier than the upper one. The force by which this is effected is the same which affects the perfect and uniform mixture of oxygen and nitrogen in the atmosphere, and is called the force of diffusion.

The proportions of these gases in air is 4 volumes of nitrogen to 1 volume of oxygen; and, by weight, about 79 parts of nitrogen to 21 of oxygen, which is very nearly in the proportion of 2 eqs. N to 1 eq. O, or $N_2\,O$.

Besides these gases, air contains also, as essential ingredients, watery vapour in variable amount, and carbonic acid and ammonia in very small proportion. It contains also traces of all volatile substances in quantities too small to be ascertained.

The uses of the air are well known It is essential to

the life of animals, which respire it, consuming its oxygen, and replacing it by carbonic acid gas. It is equally essential to plants, which consume its carbonic acid, replacing it by oxygen, and which also consume its ammonia. By its oxygen it supports combustion and the decay of dead organic matter, both of which also replace the oxygen they consume by carbonic acid.

It is of great importance to be able to ascertain the amount of oxygen in air, because that gas is constantly consumed by respiration, combustion, and decay. This is called eudiometry, and is done in various ways. The oxygen of a measured portion is removed by phosphorus, or by copper clippings moistened with acid; or the air is mixed with a known volume of hydrogen, not less than $\frac{4}{10}$ths, or half the volume of the air, and the electric spark passed through the mixture, or spongy platinum introduced. In either case the hydrogen unites with the oxygen, both gases disappear, and water is formed, leaving the nitrogen with any excess of hydrogen. The loss of volume, divided by 3, gives the volume of the oxygen. Thus, if 100 volumes of air are mixed with 50 of hydrogen, and exploded over mercury by the electric spark, the 150 volumes are found reduced to 90, while water is deposited. The loss of volume here is 60 volumes. But in water there are 2 volumes of hydrogen to 1 volume of oxygen; consequently 60 volumes of the gases which have disappeared consist of 40 of hydrogen and 20 of oxygen; or $60 \div 3 = 20$ volumes—the amount of oxygen in 100 volumes of air.

Fig. 16.

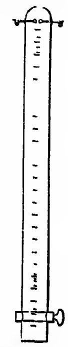

Fig. 17.

Air is thus found, where it has perfect freedom of motion and mixture, to contain everywhere 20 volumes of oxygen in 100, whether it be examined in towns, in the country, at the level of the sea, or on the highest mountains. But in confined and ill-ventilated places the proportion of oxygen is found to be smaller, while that of carbonic acid is larger, and the air in consequence unfit for respiration.

The proportion of oxygen and that of carbonic acid in air, although the former amounts to 20 volumes in 100, the latter only to at most 1 volume in 1000, have been found uniform in all parts of the world, and at all times and periods. Air, hermetically sealed up 2000 or 3000 years ago, in Herculaneum, and in the Egyptian catacombs, has been found the same as at the present day. This alone would indicate that there is a relation between these two gases, oxygen and carbonic acid. But since we know that animals consume the oxygen replacing it by carbonic acid, that plants consume carbonic acid, replacing it by oxygen, and that carbonic acid contains its own volume of oxygen, we see that there is a balance between animal and vegetable life, which are mutually dependent, each restoring to the air what the other has removed, and consuming what the other has produced, and thus preserving constant the composition of the air; each while living in it rendering it fit for the life of the other. Should any cause suddenly increase the amount of one of them—and some causes, such as volcanic action, and the combustion of fuel in manufactures, &c., do tend to increase that of carbonic acid—the vegetable kingdom instantly seizes on it, more luxuriantly, purifies the air, and at the same time produces more food for animals, so that an increase of the food of plants (carbonic acid) causing an increase of vegetation, is followed by an increase of food for animals and of animal life, and thus the balance is kept up between the animal and vegetable worlds by means of oxygen and carbonic acid, the atmosphere being the scene of action.

Air contains a variable amount of water in the form of vapour. The quantity which it can take up depends on the temperature, and when it is saturated with vapour at a given temperature, cooling even to the extent of 1 degree causes a deposition of moisture, and thus gives rise to dew, rain, snow, and hail. If the air at a given temperature be not saturated with moisture, it does not deposit any until cooled down below that point at which the vapour present is sufficient to saturate it. This is called the Dew Point, and when we know the dew point at any temperature, or what is the same thing, the difference between the temperature of the air and the dew point, we can calculate, from tables constructed for the purpose, the amount of water in the air at the time. Instruments for ascertaining this are called hygrometers, and the most accurate is the dew point hygrometer, founded on the principles just explained. Some vessel or apparatus is cooled below the temperature of the air, till dew appears on its surface, and its temperature is noted. It is then allowed to become warmer spontaneously, and the temperature again noted at the moment the dew again disappears. The mean between the two temperatures is taken as the true dew point.

Air is the standard of specific gravity for gases, and its specific gravity is made 1000. 100 cubic inches of air weigh about 31·5 grains, and by weighing the same, or any known volume of another gas, its specific gravity is ascertained by a simple proportion. 100 cubic inches of hydrogen weigh only about 2·25 grains, while 100 cubic inches of oxygen weigh 34·5 grains nearly. Hence we obtain the specific gravities of—

Air,	1000·0
Hydrogen,	69·4
Oxygen,	1111 1
Nitrogen,	972·2

Air has, in perfection, all the physical properties of permanent gases. It is perfectly elastic, that is, its volume varies inversely with the pressure to which it is subjected. 100 cubic inches of air under the ordinary pressure, or that of 1 atmosphere, become 50 cubic inches under 2 atmospheres, and 200 under half an atmosphere of pressure. This is supposing the temperature unchanged; for air, like all elastic fluids, expands much when heated, and contracts when cooled. The amount of change due to heat is $\frac{1}{480}$th of the volume, at 32° Fahr. for every degree of Fahr. while the pressure is the same.

The pressure of the atmosphere depends on its weight, which, from the enormous extent of the atmosphere, is very great, amounting to about 15 lb. on every square inch of surface at the level of the sea. As we ascend, on a hill, for example, this pressure gradually diminishes, because there is less air above than before. For this reason, as before mentioned, water boils at a lower temperature as we ascend higher, the boiling point falling nearly 1° Fahr. for every 440 feet of ascent.

The pressure of the atmosphere is measured by the barometer, which consists of a long tube, first filled with mercury, and then inserted with the open end in a cup of that liquid. The mercury falls to about 29 or 30 inches, and remains stationary at that point, the weight of the column of mercury in the tube being counterpoised by that of the air, pressing on the surface of the mercury in the cup.

By means of this instrument, the details of which belong to mechanical philosophy, the pressure of the atmosphere is found to be constantly varying, in the same place, between certain limits, from about 28 inches of mercury to 31 inches. This depends on the varying amount of air over any point, which again depends on the motions caused in the air by changes of temperature and other causes, such as the rotation of the earth on its axis. These changes of pressure are the causes in part, and in part also the effects of winds, which are the motions of the air. A sudden fall in the barometer, indicating a sudden diminution of pressure,

shows the existence of a partial vacuum over the spot where it is observed. The surrounding air rushes into this vacuum with violence proportioned to its degree, and thus restores the former pressure, or a greater. Hence, a sudden fall of the barometer is invariably followed by high winds; while a steady barometer indicates steady weather. The effect of diminished pressure on evaporation has been already mentioned.

The presence of carbonic acid gas in air is easily detected by lime or baryta water, which attract it, forming the insoluble carbonates of lime or baryta. Ammonia, though always present, can hardly be detected, on account of its minute quantity. But it is easily shown to be present in rain-water, which, in passing through the air, dissolves it; by adding a drop of sulphuric acid, evaporating nearly to dryness, and adding lime, when the smell of ammonia is at once perceived. This ammonia is the source whence plants derive probably the greater part of their nitrogen, and while plants absorb it greedily, animal life, and still more the decay of dead animal and vegetable matter, restores to the air the ammonia it has lost, as fast as it is consumed; so that here also a balance exists between plants and animals in regard to a constituent of the atmosphere.

Nitric acid is formed in the air, especially during thunderstorms, partly by the oxidation of ammonia, partly, it is believed, by the direct oxidation of nitrogen. But it is not to be detected in the air, being instantly removed by water. It appears to contribute to the supply of nitrogen to plants.

Nitrogen and Hydrogen.

(1.) *Ammonia.* $NH_3 = 17$.

This very important compound, as has just been mentioned, is produced during the decay of organic matters containing nitrogen. It is formed artificially by the action of heat on such organic compounds; and it seems to be given out occasionally from volcanoes.

It is best obtained from sal-ammoniac, hydrochlorate of ammonia, or chloride of ammonium (for the salt has all these names), by heating it with slaked lime, when the ammonia is given off as a gas. The change is—

	Hydrochlorate of Ammonia.		Slaked Lime.		Chloride of Calcium.				Ammonia.
	NH_3, HCl	+	CaO, HO	=	$CaCl$	+	$2HO$	+	NH_3
or	NH_4, Cl	+	CaO, HO	=	$CaCl$	+	$2HO$	+	NH_3

Ammonia is a gas, transparent and colourless, of a very pungent and peculiar odour, and a burning taste. It must be collected over mercury, or by displacement, being lighter than air; for water instantly absorbs it, acquiring its taste and smell. It extinguishes burning bodies without itself taking fire, although a jet of it may be set fire to in oxygen gas. It is fatal to animals when inhaled. Ammonia is a very powerful base or alkali; neutralizing the strongest acids; it is, in fact, the type of all volatile organic bases, a numerous class, and belongs strictly to organic chemistry. We shall, therefore, postpone to that section the consideration of its principal relations, viewing it here as a compound of nitrogen and hydrogen.

It consists of 3 volumes of hydrogen and 1 volume of nitrogen, which form, not four, but two volumes of ammonia. It is lighter than air, its specific gravity being 590·2. Cold water absorbs about 600 times its volume of the gas, becoming thereby lighter, and acquires all its pungency, being a powerful rubefacient and diffusible stimulant. Its salts, except the carbonate, have no smell.

Although a very powerful base, it is expelled from its salts by almost all fixed bases, on account of its volatility.

Ammonia is reduced to the liquid state by a pressure of about 17 atmospheres at the ordinary temperature.

Its presence is recognised by its smell when free, and by its forming thick white fumes of sal-ammoniac when a rod dipped in hydrochloric acid is brought near it. When combined, it is first set free by the addition of lime or potash, and the tests are then applied.

The uses of ammonia are numerous. It is an important part of the food of plants, and a most valuable ingredient, therefore, in manures. It is much used by chemists in their researches, and also in medicine and pharmacy. It is commonly employed in the form of solution in water, called aqua, or liquor ammoniæ, which is made by causing a current of the gas to pass through water kept cool, till it is saturated.

Large quantities of ammonia, formed by the action of heat on coal, are now obtained from the water of gas-works in the form of sulphate.

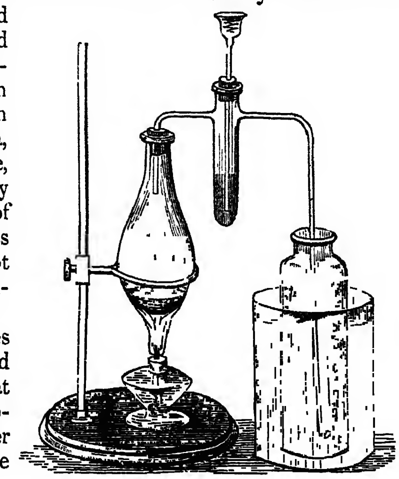

Fig. 18.

(2.) *Ammonium.* $NH_4 = 18$.

This is a hypothetical compound, or, at least, has not yet been obtained in a separate form; but there are good reasons for admitting its existence in the salts of ammonia. It is believed to have the properties, at all events the chemical properties, of a metal, and to be closely related to potassium. The arguments in favour of the existence of ammonium, are as follows:—

1. When a salt of ammonia is decomposed by the electric current in contact with mercury, the mercury is converted into a soft semisolid mass many times the volume of the mercury, which resembles entirely the compounds of mercury with metals, such as potassium, sodium, &c. Hence it is believed to contain a metal, and is called the amalgam of ammonium; the compounds of mercury with other metals being called amalgams. 2. This amalgam, left to itself, is soon decomposed, and yields nothing but mercury, ammonia, and hydrogen. Hence, if there be a metal combined with the mercury, that metal is formed of ammonia and hydrogen. 3. The salts of ammonia with oxygen acids are isomorphous with those of potash, provided they contain 1 eq. of dry acid, 1 eq. of ammonia, and 1 eq. of water. The salts of ammonia with hydrogen acids are isomorphous with those of potassium, without this 1 eq. of water. Now let us compare the formulæ of the two classes of isomorphous salts, which, according to the doctrine of isomorphism, ought to have an analogous constitution. We find—

Sulphate of potash	KO, SO_3
Chloride of potassium	KCl
Sulphate of ammonia	NH_3, HO, SO_3
Hydrochlorate of ammonium	NH_3, HCl

Here, at first sight, we perceive no analogy in either case. But if we assume that the salts of *ammonia* are really salts of *ammonium*, the analogy is at once evident, especially if we use a single symbol for ammonium, for example, Am. We have then—

Sulphate of oxide of ammonium, NH_4O, SO_3, or AmO, SO_3
Chloride of ammonium, NH_4Cl, or $AmCl$
Sulphate of potash, KO, SO_3
Chloride of potassium, KCl.

Here we see that ammonium, NH_4 or Am, and oxide of ammonium, NH_4O or AmO, can replace potassium and potash (oxide of potassium) without changing the form of the compound. Now oxide of ammonium, NH_4O, is the

same thing as ammonia *plus* water, $NH_3 + HO$, and this explains why 1 eq. of water exists in addition to ammonia in all the salts of oxygen acids with ammonia which are all likewise isomorphous with those of potash. If this eq. of water be excluded we obtain different compounds, not true salts of ammonia. For every salt of potassium there is a corresponding salt of ammonium, of like form, and perfectly analogous properties; and wherever oxide of potassium is present, it is replaced, not by ammonium, but by oxide of ammonium, in other words, by the elements of ammonia and water. There is no way known in which this remarkable analogy and isomorphism can be explained, except the hypothesis of ammonium, and it explains all the facts perfectly. The only difference between the salts of ammonium on this hypothesis and those of potassium, beyond what exists between the salts of any two analogous metals is, that while potassium is elementary, ammonium is compound. But it must be remembered that potassium, like all the elements, is not absolutely elementary but only cannot be shown to be compound, and that this may one day be done. We have been thus particular in explaining the doctrine of ammonium, because it is the type, like ammonia, of a numerous class of organic compounds, in which the analogy to potassium comes out still more strongly.

The salts of ammonia, then, on this hypothesis, now almost universally admitted, are salts of ammonium. Sulphate of ammonia, NH_3, HO, SO_3 is considered to be sulphate of oxide of ammonium, NH_4O, SO_3 or Am O, SO_3. When a hydrogen acid such as hydrochloric acid, H Cl, acts on ammonia, it is believed not to combine with it, as expressed in the old formula of sal-ammoniac, NH_3, H Cl, but to react on it, the hydrogen of the acid forming with the ammonia ammonium, with which the chlorine combines. $NH_3 + HCl = NH_4Cl = Am\,Cl$.

The reason why oxide of ammonium does not exist uncombined, seems to be, that the attraction of the oxygen for the fourth eq. of hydrogen, held as it must be by a feebler attraction than the three others, is sufficient to break up the molecule, forming water, and of course, ammonia. $NH_4O = HO + NH_3$. This result is also promoted by the very strong tendency of nitrogen and hydrogen to form ammonia.

Since ammonia *plus* water is equal to oxide of ammonium, which is isomorphous with dry or anhydrous oxide of potassium or potash, it is obvious that, to form a body analogous to and isomorphous with the hydrate of potash (caustic potash), ammonium must take up 2 eqs. of water. For we have—

Oxide of potassium, dry, KO
Oxide of ammonium, NH_4O
Hydrated oxide of potassium, KO, HO
Hydrated oxide of ammonium NH_4O, $HO = NH_3 + 2HO$

The amalgam of ammonium is best made by passing a melted amalgam of sodium into a warm solution of chloride of ammonium, when the mercury swells up till it rises out of the liquid. The amalgam of sodium should contain no more than 1 part of sodium to 10 of mercury, and it is quite liquid at little more than 100° Fahr.

(3.) *Amide.* $NH_2 = 16$.

This compound, like ammonium, is not yet known in a separate state, probably on account of its strong attraction for a third eq. of hydrogen or for other bodies. But there are, especially in organic chemistry, many compounds which appear to contain it, and are of considerable interest. They are called in general amides, and individually are named from the acids which yield them; as oxamide from oxalic acid, benzamide from benzoic acid, &c. They are always formed from a salt of ammonia (ammonium) by the separation of water, one eq. of which is formed by oxygen from the acid and hydrogen from the ammonia which is thus reduced to amide. To take an example—benzoate of ammonia, NH_3, HO, $C_{14}H_5O_3$ or NH_4O, $C_{14}H_5O_3$, losing 2 eqs. of water becomes benzamide, NH_2, $C_{14}H_5O_2$. Some mineral acids seem to yield amides, and amide certainly combines with metals, as with potassium, sodium, &c., and forms various inorganic compounds. White precipitate, a medicinal compound of mercury, contains mercury, chlorine, and amide. With platinum and some other metals, amide forms remarkable basic compounds, analogous to ammonia.

Indeed, there is every reason to believe that ammonia itself is not a binary compound of nitrogen and hydrogen, but is really composed of amide and hydrogen. We shall return to amide under organic chemistry, to which its most important compounds belong.

4. *Chlorine.*

Symbol Cl. Equivalent = 35·5.

Having considered, somewhat out of the natural order, the very important elements hydrogen and nitrogen, we now resume the arrangement we have adopted, and next to oxygen we find chlorine, which has many points of analogy with it, but at the same time forms part of a group in which a still more striking analogy prevails. We have entered into considerable detail in regard to the preceding elements, a knowledge of which is essential to the understanding of the principles of chemistry, and which are also of the highest practical importance; but our space will not permit us to describe so minutely the remaining elements, nor is it necessary to do so, since the laws already explained apply to all.

Chlorine is found in vast quantities, combined with sodium in sea and rock salt, a compound which is present in every natural water, more or less, and also in all plants and animals. A few other metals such as potassium, calcium, magnesium, lead, mercury, and silver, occur in combination with chlorine; the three first in sea-water, and chloride of potassium in the ashes of plants, and in the animal juices.

It is prepared by the action of hydrochloric acid on peroxide of manganese, or by that of sulphuric acid and chloride of sodium on the same oxide. The first process is—

Peroxide of Manganese.		Hydrochloric Acid.		Chloride of Manganese.		Water.		Chloride.
MnO_2	+	2 H Cl	=	Mn Cl	+	HO	+	Cl

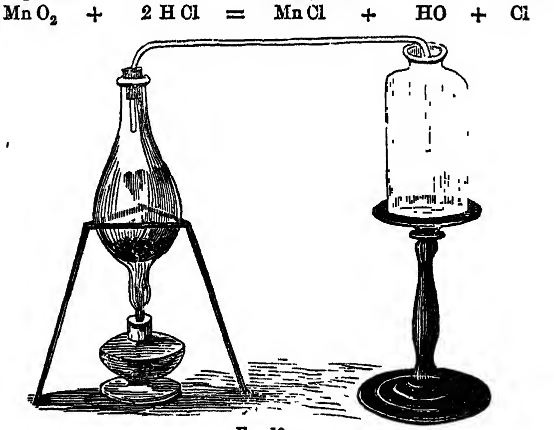

Fig. 19.

The second, which is the manufacturing process, is thus represented.

Peroxide of Manganese.		Chloride of Sodium.		Sulphuric Acid.		Sulphate of Soda.		Sulphate of Manganese.		Chlorine.
MnO_2	+	Na Cl	+	$2\,SO_3$	=	(NaO, SO_3)	+	(MnO, SO_3)	+	Cl

Chlorine is a greenish-yellow gas (hence its name), which may be collected over warm water, or by displacement, being heavier than air. It is absorbed both by cold water and by mercury. It has a very pungent and suffocating smell, and irritates the air passages dreadfully, unless much diluted. Its specific gravity is 2500. Under a pressure of about 4 at-

mospheres it is liquefied. Water absorbs several times its volume of the gas, acquiring its odour.

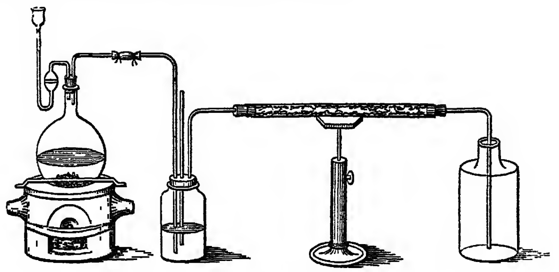

Fig. 20.

In chlorine gas, a candle burns with a feeble smoky flame, the hydrogen of the tallow alone combining with it, while the carbon is separated as smoke. A jet of hydrogen, when heated by a flame, readily burns in chlorine with a pale light, forming hydrochloric acid. Phosphorus, and most metals in a state of fine division, take fire spontaneously in chlorine, forming chlorides. Perhaps the most striking properties of chlorine are those of bleaching vegetable colours, and of destroying fetid or noxious effluvia. These effects it produces apparently by its attraction for the hydrogen, which is present in all such bodies. Chlorine is remarkable for the strength of its attractions for the more positive elements, such as hydrogen and the metals. With hydrogen it forms an acid, with oxygen several acids, with metals it forms salts.

Chlorine is much used for bleaching, and for disinfecting. Much diluted with air, it is also used with advantage for inhalation in pulmonary affections. Many of its compounds, such as hydrochloric acid, and chloride of sodium or sea-salt, are of great utility and value. In describing its compounds with the preceding elements, we shall take that with hydrogen first, as the most important.

Chlorine and Hydrogen.

Hydrochloric Acid. $H\,Cl_s = 36\cdot5$.

Chlorine and hydrogen gases, when mixed, do not combine till exposed to the sun's rays, when they combine with explosion; or to diffused light, when the combination takes place more slowly; or when a flame is introduced or the electric spark passed through them, in both which cases explosion ensues, hydrochloric acid being formed.

The acid is best prepared by the action of oil of vitriol (sulphuric acid), aided by heat, on sea-salt, which is as follows:—

	Sea Salt.		Sulphuric Acid.		Sulphate of Soda.		Hydrochloric Acid.
	$NaCl$	+	HO, SO_3	=	NaO, SO_3	+	HCl
or	$NaCl$	+	H, SO_4	=	Na, SO_4	+	HCl

It is a colourless transparent gas, of a pungent and suffocating acid smell, and very sour burning taste, forming gray fumes with the moisture of the air. It has an intense attraction for water, which instantly absorbs it, and must be collected over mercury, or by displacement. It is rather heavier than air, being formed of

1 vol. chlorine,	weighing	2500
1 vol. hydrogen,	...	69·4
which yield 2 vols. hydrochloric acid,	. .	2569·4
So that 1 vol. of hydrochloric acid must weigh		1284·7

This acid, like all similar ones, forms thick white vapours with ammonia. These vapours in this case are solid particles of sal-ammoniac or chloride of ammonium, and are soon deposited as a powder.

Hydrochloric acid gas is absorbed by water, which takes up if kept cool about 500 times its volume of the gas, increasing considerably in bulk and also in density. The saturated solution has the specific gravity 1210, fumes strongly, and is corrosive. This solution is the form in which the acid is chiefly used, and is best made by heating 1 eq. of salt, with 2 eqs. of oil of vitriol, previously diluted with rather less than half its bulk of water. The gas is conducted by a bent tube into a bottle containing cold water, which is kept cool, the tube just dipping below the surface. However rapid the current of gas, not a particle escapes, if the water be kept cool, till it is saturated. The water becoming heavier as it absorbs the gas, descends, lighter particles taking its place, and thus a constant mixture is effected without external agitation.

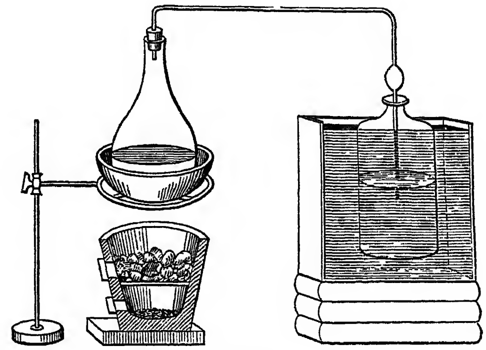

Fig. 21.

This aqueous solution of the acid, commonly called liquid hydrochloric acid, is a most valuable solvent for mineral substances. It converts metals and metallic oxides into chlorides, most of which are soluble in water. If M be any metal, and MO any metallic oxide, then we have

$$M + HCl = MCl + H, \text{ and } MO + HCl = HO + MCl.$$

The only insoluble chlorides are those of silver and mercury (protochloride).

Both in itself, and in its action on metals, and on their oxides, hydrochloric acid is the type of acids in general. For, as we have already explained under hydrogen, sulphuric acid and other oxygen acids may be viewed as compounds of hydrogen with compound radicals, instead of being regarded as consisting of anhydrous or dry acids and water. Let X stand for any acid radical or salt radical, simple or compound, M for any metal, H for hydrogen; we then have the following general formulæ, examples of which are placed below each:—

General Formulæ.	Acid.	Salt.
	HX	MX
Radical chlorine, Cl	HCl	MCl
Radical of sulphuric acid, $SO_4 = Su$	HSu	MSu
Radical of nitric acid, $NO_6 = Nt$	HNt	MNt
Radical cyanogen, $C_2N = Cy$	HCy	MCy

We shall see that there are several other acids with simple radicals, analogous to hydrochloric acid. At present, our object is to show that hydrochloric acid is the type also of those acids which contain compound radicals, when viewed in this manner, and that chlorides of metals are the types of the salts of those acids, in point of constitution, just as sea-salt, (chloride of sodium), is the type of all salts in reference to properties.

Hydrochloric acid gas has been liquefied by high pressure and cold combined.

Chlorine and Oxygen.

Chlorine has no very strong affinity for oxygen, but can be made to combine with it indirectly, forming several compounds, which are remarkable in general for being easily decomposed, often with explosion, on account of the feeble attraction between these elements. These compounds are difficult to study, for this reason, and are not fully understood. We shall therefore notice them briefly, only dwelling a little on the most important. They form two well

marked groups, both acid; but those of the second group are the more permanent.

1st Group.—Bleaching and explosive compounds.

These seem to be three in number, namely, 1. Hypochlorous acid, ClO; 2. Chlorous acid, ClO_3; and, 3. Hypochloric acid, CO_4. They are all either gaseous, or extremely volatile liquids, all of a much deeper yellow colour than chlorine; all explode on very slight causes, separating into chlorine and oxygen; and all possess bleaching properties, due probably to the easy separation of the chlorine they contain. They are only to be obtained by indirect processes, such as the action of chlorine on peroxide of mercury, that of hydrochloric acid on chlorate of potash, and that of sulphuric acid on the same salt. They are very dangerous, exploding with violence on the approach of a flame, often from a very slight rise of temperature, or even from the pressure of an inch or two of mercury. They seem to form among themselves compounds of similar properties, some of which compounds have been described as chlorochlorous and chloroperchloric acids. But their composition is still rather doubtful, from the extraordinary similarity of properties in all. Only one of them is practically important, and that one, hypochlorous acid, only in the form of a somewhat complex substance, containing one of its salts, namely, the bleaching powder, or chloride of lime, as it is inaccurately called. As the formation of this compound is connected with that of chloric acid, we shall describe both processes together.

2d Group.—Colourless, permanent, strongly acid compounds.

These are two in number, namely, 4. Chloric acid, $Cl\,O_5$; and, 5. Perchloric acid, $Cl\,O_7$.

Chloric acid, $Cl\,O_5 = 75{\cdot}5$, is chiefly important and useful in the form of chlorate of potash, which is prepared as follows:—A current of chlorine gas is passed through water, in which slaked lime is suspended until the lime is entirely dissolved. In this first stage of the process, there is formed the bleaching liquor, or solution of bleaching powder. The powder is made by placing dry slaked lime in contact with chlorine gas till it refuses to absorb any more. The bleaching powder of commerce, thus prepared, contains a good deal of unaltered lime, which is left undissolved when it is acted on by water. The solution of bleaching powder thus made is the same as the bleaching liquor prepared by passing chlorine through a mixture of lime and water.

The change, in the formation of the bleaching compound, is as follows:—

$$\underset{\text{Hydrate of Lime.}}{2\,CaO,HO} + \underset{\text{Chlorine.}}{Cl_2} = \overbrace{\underset{\text{Hypochlorite of Lime.}}{(CaO,\,ClO)} + \underset{\text{Chloride of Calcium.}}{CaCl}}^{\text{Bleaching compound.}} + \underset{\text{Water.}}{2\,HO}$$

The bleaching compound is thus a sort of double salt, formed of hypochlorite of lime and chloride of calcium, and contains the elements of 2 eqs. lime and 2 eqs. chlorine; hence the common name of chloride of lime.

This substance only bleaches in contact with acids. When it seems to do so alone, which it does very slowly, it is from the action of the carbonic acid of the air on it. The stronger acids at once disengage the whole 2 eqs. of chlorine, hence the very powerful bleaching action. The change is as follows, with sulphuric acid:—

$$\underset{\text{Bleaching Powder.}}{(CaO,\,ClO) + CaCl} + \underset{\text{Sulphuric Acid.}}{2\,SO_3} = \underset{\text{Sulphate of Lime.}}{2\,(CaO,\,SO_3)} + \underset{\text{Chlorine.}}{Cl_2}$$

Now, from the bleaching solution we can prepare chlorate of lime, and from that chlorate of potash. For, when the bleaching liquor is boiled, it loses its bleaching powers, and the following change takes place:—

$$\underset{\text{Bleaching Powder.}}{3\,[(CaO,\,ClO) + CaCl =]} \underset{\text{Chlorate of Lime}}{(CaO,\,ClO_5)} + \underset{\text{Chloride of Calcium.}}{3\,CaCl}$$

If now we add to the solution 1 eq. of chloride of potassium, and evaporate, chlorate of potash crystallizes, and only chloride of calcium remains dissolved.

$$\underset{\text{Chlorate of Lime.}}{(CaO,\,ClO_5)} + \underset{\text{Chloride of Calcium.}}{5\,CaCl} + \underset{\text{Chloride of Potassium.}}{KCl} = \underset{\text{Chlorate of Potash.}}{(KO,\,ClO_5)} + \underset{\text{Chloride of Calcium.}}{6\,CaCl}$$

In practice, the chloride of potassium is added to the bleaching solution before boiling it, when the object is to obtain chlorate of potash. This salt, being sparingly soluble in cold water, crystallizes readily when the solution is boiled down to a certain point, leaving in solution the very soluble chloride of calcium.

From chlorate of potash, chloric acid may be obtained by distillation with sulphuric acid, but when concentrated, a part is decomposed by the heat. The addition of a little water prevents this, and we obtain a solution of chloric acid nearly pure. When free from water, it forms crystals. Its solution is colourless and strongly acid, oxidizing organic matter, and forming with ammonia a dangerously explosive salt. It is only used in the form of chlorate of potash prepared as above. This salt, when heated, gives off all its oxygen quietly, as explained under oxygen. But when mixed with combustible matter, such as sulphur, phosphorus, charcoal, or sugar, the mixture deflagrates or explodes by the contact of a spark, by friction and percussion, and in the case of charcoal even spontaneously, so that it is too dangerous to be employed for gunpowder. But when duly mixed with sulphur or phosphorus, gum and water, with the addition of a little charcoal, the mixture is extensively used for lucifer matches, exploding and setting fire to the sulphur on the match, by friction on any hard body. A mixture of chlorate of potash with sugar takes fire on being touched with sulphuric acid, which, acting on the chlorate, produces hypochloric acid, and this at once sets fire to the sugar.

Perchloric acid, $Cl\,O_7 = 91{\cdot}5$, is easily obtained, in combination with potash, by heating the chlorate of potash till $\frac{1}{3}$d only of its oxygen is expelled, which is known by the melted salt becoming quite thick and pasty, and requiring a stronger heat to expel the remaining $\frac{2}{3}$ds of the oxygen. The cooled mass consists of perchlorate of potash and chloride of potassium; thus—

$$\underset{\text{Chlorate of Potash.}}{2\,(KO,\,ClO_5)} = \underset{\text{Perchlorate of Potash.}}{(KO,\,ClO_7)} + \underset{\text{Chloride of Potassium.}}{KCl} + \underset{\text{Oxygen.}}{O_4}$$

It is dissolved in the smallest possible quantity of boiling water, and on cooling the very sparingly soluble perchlorate of potash crystallizes. This salt distilled with sulphuric acid and a little water, yields a solution of perchloric acid; the acid when dry forms crystals. Perchloric acid is colourless and strongly acid. It produces in all solutions of potash a very sparingly soluble precipitate of perchlorate of potash, quite insoluble in weak alcohol. Hence the acid is used to distinguish and to separate potash from soda, the perchlorate of soda being very soluble even in alcohol.

Perchlorate of potash explodes feebly with combustible matter on heat being applied. It is not easy to see how an acid containing 7 eqs. of oxygen should be less disposed to yield oxygen to combustible matter than one with 5 eqs. only. But there is evidently something in the constitution of the molecule which renders it more permanent than that of chloric acid, which itself is far more permanent than those of hypochloric, chlorous, and hypochlorous acids.

Chlorine and Nitrogen.

When chlorine gas is placed in contact with a warm solution of chloride of ammonium (sal-ammoniac), it is absorbed, and oily drops are formed, which sink through the liquid. These are frightfully explosive, especially on simple contact with greasy, oily, or combustible substances. This explosive compound has been described as a compound of nitrogen with chlorine, $N\,Cl_4$, or, according to some, $N\,Cl_3$. But very recent researches have shown that this is not the case, and

that this compound contains also hydrogen. We do not therefore, at present, know any compound of these elements.

5. *Bromine.*

Symbol Br. Equivalent = 80.

Bromine stands unquestionably next to chlorine, and is so very analogous to it, that a very brief notice will suffice. It is found united to sodium, potassium, or magnesium, in very small proportion, in sea-water, and in saline springs. Those of Kreuznach are comparatively rich in bromides, as is also the water of the Dead Sea, which is simply a concentrated sea-water.

It is obtained from the mother liquor or bittern which remains after salt-water has been evaporated to yield crystals of salt, and refuses to yield any more. This liquid contains much of the chlorides of potassium, calcium, magnesium, and a small proportion of some bromide or bromides. If we pass through it a current of chlorine, or, what is the same thing, add to it a little sulphuric acid and peroxide of manganese, which, with the chlorides, produce free chlorine;

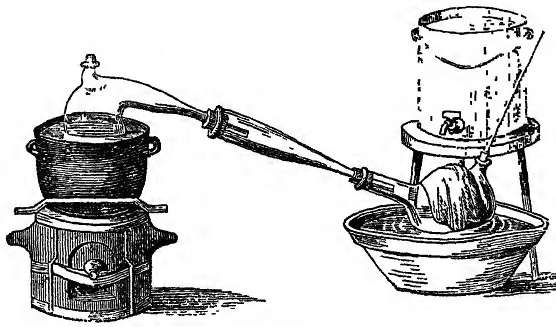

Fig. 22.

the chlorine displaces the bromine, which, being set free, colours the liquid of a strong orange-yellow. Heat is applied, and the vapour of water, distilling over, carries with it the vapour of bromine, which collects in the receiver, partly as heavy drops of a deep red colour, which are pure bromine, partly as an aqueous solution of bromine of an orange colour, which floats above. Excess of chlorine must be avoided, as it combines with the bromine, forming a chloride of bromine. If the aqueous solution be shaken with a little ether, the ether dissolves the bromine and rises to the surface, of a deep red colour. This is added to the nearly pure bromine collected below, and the whole is then mixed with as much solution of caustic potash as entirely destroys the colour, by which the bromine is converted into two salts, bromate of potash and bromide of potassium. (Chlorine with potash undergoes a similar change, and chlorate of potash was formerly thus prepared.) The change is represented as follows:—

Bromine.		Potash.		Bromate of Potash.		Bromide of Potassium.
Br_6	+	6 KO	=	KO, Br O_5	+	5 K Br

The solution is dried up and ignited, which expels the oxygen of the bromate, converting it also into bromide; so that we have (KO, Br O_5) + 5 K Br = 6 K Br + O_6. Lastly, the bromide of potassium is heated with sulphuric acid, a little water, and peroxide of manganese, when pure bromine passes over, with some water. The greater part of the bromine collects below an aqueous solution of a small part of it, and may be withdrawn by a pipette.

Bromine is a heavy dark red volatile liquid, of a most pungent odour, strongly affecting the mucous membrane of the nose and eyes, and producing a profuse catarrhal discharge. Its vapour must be carefully avoided. It is named, indeed, from its strong smell. Its vapour or gas is of the same red colour as that of nitrous acid, and very dense, its specific gravity being about 5500, rather more than twice as heavy as chlorine gas. Bromine is very poisonous; a drop placed on the beak of a small bird soon proving fatal. It has feeble bleaching properties compared to chlorine.

Bromine is in all its relations so perfectly analogous to chlorine, that it is unnecessary to go into detail. What is true of chlorine is true of bromine, with regard to the other elements, in all cases where bromine combines with them. The chief difference is, that its equivalent is higher, and its affinities weaker, than those of chlorine, which displaces it from all its compounds.

With hydrogen it forms hydrobromic acid, H Br_6; equivalent = 81; perfectly analogous to hydrochloric acid, but much more dense. It is absorbed by water with even greater energy.

With oxygen it forms bromic and perbromic acids, analogous in composition and properties to chloric and perchloric acids. Bleaching oxides or acids of bromine are not yet known.

To bromine and nitrogen the same remarks apply as to chlorine and nitrogen. The compounds of bromine with metals are so like those of chlorine, that they are hardly distinguishable from them.

Bromine will probably be found useful in medicine. At present its chief use is, with chlorine and iodine, in photography. It contributes to the formation of the most sensitive surfaces.

6. *Iodine.*

Symbol I. Equivalent = 127.

This element is the third of the remarkable group, of which the two other members have just been described. It is found in the ashes of marine plants, which form kelp, varec, and barilla. It is, no doubt, derived by the plants from the sea-water; but its proportion in that water is so small as hardly to admit of being detected directly. It is also found in the ashes of many land plants, especially such as grow near the sea; in some salt springs in small proportion, and in a few rare minerals.

It is obtained from kelp, after all the crystallizable salts have been separated by evaporation. The residual or mother liquid contains the iodide of sodium, potassium, or magnesium, mixed with chlorides, sulphurets, and sulphites, as well as various other impurities. It is extracted by adding first an excess of sulphuric acid, which disengages a vast amount of gases, hydrosulphuric and sulphurous acids, and causes a copious deposition of sulphur. On cooling, sulphates of soda, potash, and magnesia, are deposited, and the liquid, poured off from these, is heated with peroxide of manganese as long as purple vapours of iodine come off. In another method the iodine is precipitated as subiodide of copper, Cu_2 I, which is afterwards decomposed by sulphuric acid and peroxide of manganese. The vapours of iodine condense into crystals in the receiver, along with some water.

Iodine is a black solid, crystalline, very brittle, of a quasi-metallic lustre, and volatile. When dry it is converted into vapour, without melting, at 320° nearly; but if water be present the iodine passes rapidly over at 212°. Its vapour is of a fine purple or violet colour, hence the name, and is very heavy, being nearly 9 times denser than air. Heated under pressure, iodine melts to a brown liquid. It is almost insoluble in water, 1 part requiring 7000 of cold water to dissolve it; but even this colours the water brown. It is very soluble in alcohol, ether, and similar liquids. Iodine hardly possesses bleaching properties. It stains organic matter deep yellow, and corrodes it (for example, paper) rapidly. Its distinguishing character is that of striking, with a cold infusion of starch or with starch paste, a deep blue. The blue substance seems not to be a definite compound, but to consist of starch, with minute particles of iodine mechanically diffused through and adhering to it. The violet-blue colour seems to be that of finely-divided iodine, as is seen in its vapour. Heat destroys the colour of the iodide

of starch. This character distinguishes iodine from bromine, which colours starch brown.

Iodine is entirely analogous to chlorine and bromine; the three bodies forming a group in which bromine stands in every point, in form, density of vapour, strength of affinity, and atomic weight, precisely between chlorine and iodine. As bromine is perfectly analogous to chlorine in its compounds, so iodine is analogous to bromine.

With hydrogen it forms hydriodic acid, HI, which is so similar to hydrochloric and hydrobromic acids, that it cannot be distinguished from them, except by proving that it contains iodine. It is a colourless acid gas absorbed to a prodigious extent by water, forming gray fumes in moist air, and white fumes with ammonia. To obtain it, iodine is first placed in contact with phosphorus, in a tube filled with carbonic acid gas, to exclude oxygen. The two bodies combine with a flash of light, forming, according to the preparations used, either the teriodide of phosphorus, PI_3, or the periodide, PI_5. When cold, water is added, a conducting-tube adapted, and heat applied. The action is as follows, taking the periodide; but it is the same, *mutatis mutandis*, for the other:—

Periodide of Phosphorus.		Water.		Phosphoric Acid.		Hydriodic Acid.
PI_5	+	5 HO	=	PO_5	+	5 HI

The action of hydriodic acid on metals and on metallic oxides is exactly analogous to hydrochloric or hydrobromic acid. An iodide of the metal is formed; and in the one case hydrogen is liberated, in the other water is produced. The iodides of some metals have fine colours. Iodide of lead is bright yellow; periodide of mercury is of a bright scarlet.

With oxygen iodine is not known to form any bleaching compounds, but it forms iodic acid, IO_5, and periodic acid, IO_7, corresponding to chloric and perchloric acids. Iodate of potash is formed, along with iodide of potassium, when iodine is acted on by caustic potash, precisely as in the case of bromine and chlorine, $I_6 + 6\,KO = KO, IO_5 + 5\,KI$. The mixed salts being dried, alcohol dissolves the iodide, leaving the iodate, from which iodic acid may be obtained if required. Iodine may also be oxidized into iodic acid by boiling with the strongest nitric acid. Iodic acid is a crystalline solid, very soluble and very acid. Periodic acid is formed by a circuitous, indirect process. It is not applied to any use.

The compound, an explosive black powder, hitherto called iodide of nitrogen, appears from recent researches to have a different composition.

Iodine combines both with chlorine and bromine. With chlorine it forms several compounds, one of which is so like bromine, that when bromine was accidentally obtained by Liebig from the water of Kreuznach, which contains both chlorine and iodine, he took it for chloride of iodine, and thus missed the discovery of bromine, which was soon after made by Balard. The supposed chloride was then found to be pure bromine.

The compounds of chlorine both with bromine and iodine, as well as those of bromine and iodine, have nearly intermediate characters, and are not very precisely known. They are all more or less used in photography.

The iodides of metals, as well as the bromides, are entirely analogous to the chlorides, but are, those of iodine more particularly, less soluble in water.

Iodine is much used in medicine, both as iodine in tincture and ointment, and in the form of iodides, such as those of potassium, iron, zinc, lead, and mercury.

The extraordinary analogy between the three elements just considered seems to indicate something common to all three. But if they contain a common element, they must be really compounds, for their differences must depend on something peculiar to each. It is worthy of notice that the relation between them as to physical properties, affinity, and atomic weight, is precisely that between three contiguous members of what is called in organic chemistry a series of homologous compounds. Thus methylic alcohol, ethylic alcohol, and propylic alcohol, form a precisely parallel group. Now, the first of these is converted into the second by the addition of $C_2\,H_2$, and the second into the third in the same way:—

Methylic alcohol, ...	$C_2\,H_4\,O_2 + C_2\,H_2$
Ethylic alcohol, ...	$C_4\,H_6\,O_2 + C_2\,H_2$
Propylic alcohol, ...	$C_6\,H_8\,O_2$ &c &c

It is therefore quite conceivable that there may be a similar relation between chlorine and bromine, bromine and iodine. But as to what is here the common difference, corresponding to $C_2\,H_2$ in the other case, we can say nothing. We can only point out the probability that such a relation exists, and leave the question to be decided by research, when our means of research shall have been improved; for hitherto all our efforts to convert chlorine into bromine, or bromine into iodine, and *vice versa*, have failed.

7. *Fluorine.*

Symbol F. Equivalent = 18·9.

This element is not yet known in a separate form; but from the character of all its compounds, it is obviously very analogous to the three preceding elements. The reason why we have not yet obtained it uncombined is, that its affinities are so powerful, that it corrodes all vessels in which the attempt has been made. It has been suggested that it might be isolated in vessels of fluor-spar; but no distinct results have yet been obtained. According to some it is a yellow gas like chlorine; but there is reason to think that chlorine was at all events mixed with the supposed fluorine.

Fluorine is found in nature combined with calcium as fluor or Derbyshire spar, and occurs also in small proportions in mica, topaz, cryolite, and a few other minerals. Fluoride of calcium, or fluor-spar, is also an essential ingredient, in small proportion, of bones, and is to be detected almost everywhere, in rocks, soils, springs, the sea, the ashes of plants, and the animal fluids, but in very minute quantity.

With hydrogen, fluorine forms its most important compound, hydrofluoric acid (often called fluoric acid), HF, = 19·9. This acid is obtained by distilling fluor-spar with sulphuric acid in vessels of lead, silver, gold, or platinum, for it corrodes glass and porcelain. The change is as follows:—

Fluoride of Calcium.		Sulphuric Acid.		Sulphate of Lime.		Hydrofluoric Acid.
Ca F	+	HO, SO_3	=	$Ca\,O, SO_3$	+	HF

It forms a very volatile, fuming, and frightfully corrosive liquid, which produces intense heat when mixed with water; and a drop of which falling on the skin produces, even when instantly washed away, a very painful sore, which is extremely difficult to heal. The hands should be protected even against the vapour, for it penetrates under the nails, producing there sores which, from their confined position, cause intolerable pain.

It is in its relations very analogous to hydrochloric acid, &c., acting on metals and metallic oxides in the same way, and forming fluorides very similar to the chlorides. Its distinguishing character is its power of corroding glass and all silicious compounds, in virtue of the strong affinity of fluorine for silicon, with which it forms a gaseous compound. This property is not only applied to etching on glass, but to the detection of minute traces of fluorine or fluorides. The substance suspected to contain it, whether an ash, a mineral, the residue of any water, or the deposit from sea-water when boiled, is placed in a platinum vessel with pure sulphuric acid. A plate of glass is covered with melted wax, and when cold, marks are traced in the wax with a sharp point, which exposes the glass under these

marks. The plate is then laid over the vessel with the materials, to which a very gentle heat is applied. The vapour of hydrofluoric acid, if a fluoride be present, rises and acts on the exposed lines. After a certain time, longer in proportion as the amount of fluorine is smaller, the wax is removed, and the lines are found indelibly etched on the glass.

The only use to which hydrofluoric acid is applied is that of etching on glass, and dissolving silicious minerals for analysis, by which means the whole silica is dissipated as gas, and the other elements remain. The presence of fluoride of calcium in bones is probably connected with their hardness and toughness. It is conjectured that the presence of the fluoride prevents the phosphate of lime from crystallizing, as it has a strong tendency to do, and thereby becoming brittle. Fossil bones and coprolites, rich in bone earth, invariably contain a small amount of fluoride of calcium. It has been said that the proportion is greater in fossil than in recent bones; but it seems rather that, from the absence of animal matter, it is more readily detected in the former.

No compounds are yet known of fluorine with oxygen, nitrogen, chlorine, bromine, or iodine. Its affinities are so very powerful for the positive elements, that it is probable it may prove to be more highly negative than oxygen, which would account for its exhibiting little or no attraction for that element.

(B.) POSITIVE OR COMBUSTIBLE METALLOIDS.

8. *Carbon.*

Symbol C. Equivalent = 6.

This most important element occurs in nature in several forms, more or less pure. Crystallized, it is found in two allotropic forms; one transparent, hard, and colourless, is the diamond, the other black and soft, is plumbago or black lead, or graphite, the crystalline form of which is quite different. A third, amorphous form, is found in anthracite or blind coal. It occurs also, combined with oxygen, as carbonic acid gas, in the atmosphere, in waters, in the chokedamp of mines, in volcanic districts; and the same acid, combined with lime, forms marble, limestone, chalk, shells, calcareous deposits, and calcareous or Iceland spar. Other carbonates occur in the mineral kingdom, such as those of magnesia, iron, lead, copper, &c. Carbon is the chief ingredient of all animal and vegetable substances; also of coal, which is vegetable matter in an altered state, and of peat, lignite, brown-coal, wood-coal, jet, asphalt, bitumen, &c., all of which have a similar origin.

Pure carbon, in the form of diamond, which forms octahedral crystals, is distinguished by its extreme hardness and by its action on light, giving it the fine play of colours for which it is valued. Graphite occurs in micaceous scales, which are short prismatic crystals. It is black and opaque, with somewhat of a metallic lustre. Anthracite has no regular form, and is dull, black, and opaque. So also are wood, charcoal, and lamp-black; the latter being pure carbon from oils or resins, the former, like anthracite, containing, as ashes, the mineral elements of the plants which yielded them. In all its forms it is a bad conductor of heat, but when dense and compact it conducts electricity. It is totally infusible by any heat we can produce. When heated to redness in air or oxygen, it burns without flame, frequently with sparks, forming carbonic acid gas. Diamond can easily be burned in oxygen, or even in air, by the heat of a glass-house furnace. No liquid is yet known which can dissolve carbon as such.

Carbon has the power of attracting, in a manner somewhat obscure, both gaseous and dissolved matters, and collecting them in its pores. Thus it absorbs large quantities of most gases; and when introduced into a liquid, generally removes from it any organic colouring matter that may be present, and very frequently saline substances also. It absorbs and renders innocuous all offensive effluvia. Animal charcoal has the greatest power in this way, either because it is more porous, or because it contains nitrogen, and is not in fact pure carbon.

Carbon and Oxygen.

1. *Carbonic Oxide,* $CO = 14$.

This is a gas formed when carbon burns with an insufficient supply of oxygen, or when carbonic acid gas, CO_2 is passed over red-hot charcoal. It may be formed also by heating with excess of sulphuric acid, oxalic acid and its salts, formic acid and its salts, or ferrocyanide of potassium. When oxalic acid is employed, it is resolved into equal volumes of carbonic acid and carbonic oxide, while water combines with the sulphuric acid; thus—

Oxalic Acid.		Sulphuric Acid.		Diluted Sulphuric Acid.		Carbonic Oxide.		Carbonic Acid
$C_2O_3, 3HO$	+	SO_3, HO	=	$SO_3, 4HO$	+	CO	+	CO_2

Formic acid consists of $C_2H_2O_4$, or C_2HO_3, HO; and yields precisely in the same way water and pure carbonic oxide gas. $C_2H_2O_4 = 2HO + 2CO$. The ferrocyanide of potassium first yields hydrocyanic acid, which, by the action of mere sulphuric acid reacts on water, producing formic acid and ammonia, and the formic acid is decomposed as above. When mixed with carbonic acid, the gas is purified by means of lime or potash, which absorb the carbonic acid, leaving the carbonic oxide. It is collected over water.

It is a colourless gas of specific gravity 972·1, without taste or smell, which, when heated in air, takes fire and burns with a pure blue lambent flame, being oxidized into carbonic acid. In every large coal fire, the air entering below forms carbonic acid, which, passing through the deep mass of red-hot charcoal, is converted into carbonic oxide, thus, $CO_2 + C = 2CO$. The carbonic oxide rising to the surface, there burns with its peculiar blue flame, as may be seen in every large fire after it has burned so far that no more gas issues from the coal, and the whole is in a red glow. The blue flame is supposed to indicate frost, but it is evident that it indicates simply a large red-hot fire, which, of course, is more frequent in frosty weather than in summer.

This gas occurs in mines, along with carbonic acid and carburetted hydrogen. It is poisonous when inhaled.

Carbonic oxide, or a substance polymeric with it, seems to exist in some organic compounds as a radical. It is not applied to any use, although it has a share in the reduction of metal, such as iron, being formed in large quantity in the deep smelting furnaces, and having, from its tendency to take up an additional eq. of oxygen, a considerable deoxidizing power.

2. *Carbonic Acid,* $CO_2 = 22$.

This is a much more important compound. It is a gas which occurs abundantly in nature, as has been stated under carbon, both free and combined with lime and other bases. It is also abundantly formed in various natural and artificial processes, in the respiration of animals, in the decay of dead organic matters, in fermentation, and in combustion. It is from these sources principally that the carbonic acid of the atmosphere, so essential to vegetation, is supplied; and it is consumed by plants as fast as it can be produced, since its amount never exceeds, in free air, about $\frac{1}{1000}$th of the bulk or volume of the air.

To obtain it pure, carbonate of lime, that is, marble limestone or chalk, is acted on by diluted hydrochloric acid. The action is very simple. $CaO, CO_2 + HCl = CaCl + HO + CO_2$. Chloride of calcium and water are left, while carbonic acid gas passes off and is collected over water, which absorbs a certain amount of it, but not so much as to

 prevent us from thus collecting it. It must not, however, be left to stand over water, or it will be absorbed.

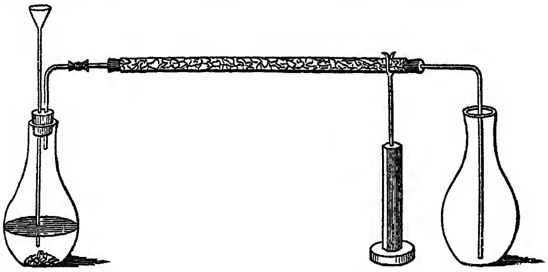

Fig. 23.

It is colourless and transparent, has a sharp acidulous taste, and a certain pungency of smell, or rather a peculiar action on the organs of respiration, and not a true odour. It extinguishes all burning bodies, and is equally fatal to animal life, being poisonous even when diluted with air, and not merely negatively injurious like nitrogen. It is distinguished from all other gases by its rendering lime-water milky from the formation of the insoluble carbonate of lime. It is a heavy gas, its specific gravity being 1527·7. We do not know the volume of the carbon in it in the state of gas, but we know that it contains its own volume of oxygen, and that the whole weight of the carbon is added to that of the oxygen in the same volume. So that we have—

One volume oxygen, specific gravity.................	1111 1
Carbon, volume uncertain, weighing	416·6
One volume carbonic acid, specific gravity.........	1527·7

If the carbon united to 1 volume of oxygen be, as gas, equal in volume to the oxygen, then 1 volume of gaseous carbon must weigh 416·6, when 1 of oxygen weighs 1111·1, and its specific gravity would be 416·6. But this would imply that the 2 volumes of the elements were condensed into 1 volume of the compound, of which we have no example. If, on the other hand, carbonic acid be formed of 2 volumes of oxygen and 1 volume of gaseous carbon, the 3 volumes condensed into 2, which is a very common occurrence, as in water, protoxide of nitrogen, &c., then the 416·6 will represent the weight only of half a volume of carbon, and the weight of an entire volume, or the specific gravity, will be 416·6 × 2, or 833·2. This latter view of the specific gravity of gaseous carbon, which cannot be directly determined, is considered the most probable. On the same supposition carbonic oxide will be formed of 1 volume of gaseous carbon and 1 volume of oxygen, united without condensation, or so as to form 2 volumes of the compound, which is also a very common occurrence, as in hydrochloric acid, &c. We have mentioned this here, to explain how chemists calculate the probable density, in the gaseous form of a substance, such as carbon, which is not known in that form, except in compounds.

From its weight, carbonic acid gas may be poured out of one vessel into another, like water; and if a lighted candle be first placed in the lower vessel, it will be quickly extinguished, as the invisible gas flows down to it. The gas may even be poured in the open air so as to fall in a narrow stream on the candle and extinguish it. For the same reason this poisonous gas is apt to accumulate in deep pits, wells, or mines, where it is very dangerous. A candle let down first will indicate, according as it burns brightly or dimly, or is extinguished, the purity or impurity of the air in such places, before any one descends; and this precaution should never be neglected. The gas often accumulates in the huge vats of the brewers, and has frequently caused fatal accidents there as well as in mines or pits. It is the choke-damp of miners.

Carbonic acid is liquefied by a pressure of 36 to 40 atmospheres, according as the temperature varies from 32° to about 60°. The condensed acid is very dangerous, having often, by its enormous pressure, burst very strong vessels and caused fatal results. It is best condensed by being forced by means of a very powerful forcing pump into a strong copper vessel, which, if it should at any time give way, tears instead of bursting. When allowed to escape through a small aperture, it assumes the gaseous form with almost explosive force, but is manageable, and if the current be made to circulate through a brass box, the evaporation of part produces a cold so intense as to solidify the rest. The solid acid is exactly like snow, and evaporates much more slowly than the liquid. But if mixed with ether, the mixture evaporates so rapidly, that by its means several pounds of mercury may be frozen hard in a minute or two. The liquid acid expands by heat to a remarkable degree.

Carbonic acid gas is absorbed by water to a small extent under the ordinary pressure, but under an increased pressure the quantity absorbed increases in proportion to the pressure; the water always absorbing about its own volume, whatever the pressure, but the gas being of course more and more condensed as the pressure increases. The solution sparkles, and has a pleasant acidulous taste, as observed in many mineral waters. The addition of a little carbonate of soda (or potash) causes water to absorb much more, and when this is combined with high pressure, a very large quantity is taken up, which escapes on the pressure being removed. This is the nature of soda water. Champagne is wine bottled before the fermentation is complete, and therefore charged with carbonic acid under pressure of the gas itself, which escapes with violence when the cork is drawn. All effervescing wines or other beverages are in the same way more or less charged with carbonic acid.

The solution of carbonic acid in pure water, or in water containing a little potash or soda, under the ordinary or a slightly increased pressure, occurs as a mineral water in many springs, especially in volcanic districts, even in such as, like Auvergne and the Eifel, have not been the scene of active volcanic action since the appearance of man on the earth. In the Eifel the soil is everywhere impregnated with the gas, which of course appears in all the springs. The Grotta del Cane, near Vesuvius, is a cave containing a small lake or pool, through which carbonic acid constantly bubbles, and from its weight remains near the floor of the cave, so that a dog, whose head is near the ground, falls down insensible, while men, whose heads are in pure air, perceive no effect. The animal recovers, if at once removed into pure air and thrown into the lake outside. This mode of applying the cold affusion is effectual in causing instinctive inhalations of pure air, and indicates the dashing of cold water on the face and chest of those poisoned by the gas as one of the most efficient remedies.

The solution of the gas in water reddens vegetable blues like other acids; but on standing, or after boiling, the blue colour returns, the acid being dissipated. This serves to distinguish carbonic acid from most other acids.

The same solution added to lime water renders it milky, by forming insoluble carbonate of lime, CaO, CO_2. But the addition of more carbonic acid clears all up again, forming the soluble bicarbonate, $CaO, 2\ CO_2$. Such a solution containing carbonate or bicarbonate of lime, dissolved in excess of carbonic acid, is exceedingly common in all districts where limestone occurs. The amount of lime present varies very much, but even a few grains per gallon render the water very hard. Such, indeed, is the usual cause of hardness in water, although the presence of sulphate of lime or gypsum also contributes to it in many cases. The rain dissolves carbonic acid as it passes through the air, and more in filtering through the soil, and when it now meets with chalk or limestone it dissolves it and becomes hard. Some waters contain 10 grains of carbonate of lime in the gallon, others a good deal more; very hard waters frequently 70 or 80 grains, and in some cases so much as 150 grains

Chemistry. and upwards. Such waters are useless for the purposes of washing, and generally for culinary purposes, and above all unfit for steam-boilers; for they deposit, on being boiled, a crust of carbonate of lime which is most injurious, and is often the cause of explosions. It is singular that hard waters—not, however, the hardest, but such as that of the Thames, and some still harder near Edinburgh, where from the abundance of the carboniferous limestones they are very common—are the best for the purposes of the brewer of ale or porter. On the small scale the carbonate of lime in hard water of this kind may be separated by boiling, but this is impracticable on the large scale. Professor Clark's process consists in adding to the water as much lime, dissolved in water (lime water), as it already contains in the form of bicarbonate, and more if there be an excess of carbonic acid beyond this. The added lime converts the soluble bicarbonate into the insoluble neutral carbonate, which is thus explained, $CaO, 2\,CO_2 + CaO = 2\,(CaO, CO_2)$.

The chief use of carbonic acid is to form the principal part of the food of plants, which derive from it, and therefore from the atmosphere, the whole of the immense quantity of carbon they contain. The carbon of the animal world being derived directly or indirectly from plants, for carnivorous animals feed on such as feed on plants, is also derived from the same source; and the carbon of dead animals and vegetables again takes, in the process of decay, the form of carbonic acid, in which it becomes the food of a new generation of plants and animals. The other uses of carbonic acid, as a remedy and in various beverages, are familiar, and have been already mentioned. The salts of this acid are characterized by effervescing with strong acids.

Some other compounds are frequently described as compounds of carbon and oxygen, such as oxalic, acid, mellitic acid, &c. But in fact they all contain hydrogen also, and belong to organic chemistry.

Carbon and Hydrogen.

The compounds of these two elements are extremely numerous, far more so than those of any two elements whatever. Indeed there seems hardly any limit to their number. They are all of organic *origin*, and belong to organic chemistry, under which we shall describe them more particularly. Here we shall only say, that, being formed of two combustibles, they are all eminently combustible, and are used as combustibles. They occur in all forms, solid, liquid, and gaseous; and of all different proportions of the two elements. They form various series, some of which are homologous, others polymeric. In one homologous series, that of olefiant gas, the proportion is that of 1 eq. of each, but the absolute amount varies from C_2H_2 and C_4H_4, which are gaseous, to $C_{16}H_{16}$, &c., which is liquid, and to $C_{54}H_{54}$ and $C_{60}H_{60}$, which, with many others, are solid. In another exactly parallel series, that of marsh gas, the proportion is such that there are always 2 eqs. of hydrogen more than of carbon. It begins with C_2H_4, C_4H_6, and so on to $C_{10}H_{12}$, $C_{32}H_{34}$, $C_{60}H_{62}$, &c.; those low in the scale being gaseous, those higher liquid, and higher still solid. We find similar characters in the series of methyle and ethyle, in which the hydrogen always exceeds the carbon by 1 eq.; thus we have methyle C_2H_3, ethyle C_4H_5, amyle $C_{10}H_{11}$, cetyle $C_{32}H_{33}$, melissyle $C_{60}H_{61}$, &c. As an example of another kind of series of carbo-hydrogens, we may mention certain essential or volatile oils, such as oil of lemons C_5H_4, oil of turpentine $C_{10}H_8$, another oil $C_{20}H_{16}$, &c. All these matters belong to organic chemistry, and therefore we only indicate them very briefly, that the reader may see how very peculiar is the relation of carbon to hydrogen, which is evidently connected with the fitness of these elements to constitute organic, that is, animal and vegetable compounds. Coal gas, naphtha, paraffine, and many volatile oils, belong to this group of compounds, which therefore admits of many useful applications. The fire-damp or explosive gas of mines is a mixture of some gaseous carbo-hydrogens with air.

Carbon and Nitrogen.

These elements, under certain circumstances, combine to form a very remarkable and important compound, namely, Cyanogen, C_2N or Cy, which is a compound acid radical or salt radical, entirely analogous to chlorine in its chemical relations.

Cyanogen, $C_2N = Cy = 26$, is found, as hydrocyanic acid, in oil of bitter almonds; but as that is a product of fermentation, and is not present in the dry seeds, it is doubtful whether hydrocyanic acid exist ready formed in plants. But there must be some compound of cyanogen, which, when water is added to the bitter almonds, or to the kernels of stone fruit, produces hydrocyanic acid. As urea is formed from cyanic acid and ammonia, it is probable that the animal body also contains some compound of cyanogen.

It is formed artificially when organic matter containing nitrogen is exposed to heat in close vessels. But being gaseous, it is dissipated and lost, unless some means be taken to prevent this. If potash or carbonate of potash be added, cyanide of potassium is formed, and this salt is permanent at a red heat. When water is added, however, to the heated mass, consisting chiefly of animal charcoal and cyanide of potassium, that salt is decomposed, as follows: $K, C_2N + 5\,HO = KO, 2\,CO_2 + NH_3 + H_2$; that is, bicarbonate of potash is left, and ammonia and hydrogen are given off. To obtain cyanogen in a permanent form, there must be added, either before or with the water, iron, oxide of iron, or sulphuret of iron, all of which are dissolved by cyanide of potassium. Suppose iron to be used, then $3\,(K\,Cy) + Fe + HO = (2\,K\,Cy + Fe\,Cy) + KO + H$. With oxide of iron no hydrogen is given off; and with sulphuret of iron sulphuret of potassium, KS, is formed, instead of KO; but in all these cases the compound $2\,K\,Cy + Fe\,Cy = Cy_3\,K_2\,Fe$, which is ferrocyanide of potassium, is formed. On evaporation this salt forms large and fine yellow crystals, which are very permanent, and are manufactured on the large scale, and of great purity, being much used in dyeing and calico-printing.

This salt may be viewed either as a double salt, composed of 2 eqs. K Cy with 1 eq. Fe Cy, or, as is now generally admitted, as formed of the compound radical ferrocyanogen $Cy_3\,Fe = Cfy$, which, being bibasic, takes up 2 eqs. of potassium, forming the yellow salt, Cfy, K_2. The crystals contain in addition 3 eqs. water, and are Cfy K, 3 HO.

From this salt all the compounds of cyanogen and cyanogen itself are prepared. To yield cyanogen, it is heated with bichloride of mercury, which acts on the 2 eqs. K Cy, that are present by their elements; $2\,K\,Cy + Hg\,Cl_2 = 2\,K\,Cl + Hg\,Cy_2$. This forms bicyanide of mercury, but the heat employed decomposes this salt into cyanogen and mercury.

Cyanogen is a colourless gas, collected over mercury, of a very pungent smell, inflammable and burning with a pink flame. Water absorbs it, and the solution, if kept, undergoes a spontaneous change, by which numerous compounds are formed, a kind of putrefaction. Cyanogen and water contain the four elements, carbon, hydrogen, nitrogen, and oxygen, and there are formed compounds of these, and compounds of these compounds again, so as to give rise to very complex changes. Carbonic acid, ammonia, hydrocyanic acid, cyanic acid, cyanate of ammonia, urea, formic acid, and dark brown insoluble compounds containing cyanogen, but not fully studied, are formed.

Cyanogen is very analogous to chlorine in its relations. It forms with hydrogen hydrocyanic acid, H Cy, and with

metals cyanides, corresponding to the chlorides, as K Cy and $Hg\,Cy_2$, corresponding to K Cl and $Hg\,Cl_2$. With oxygen it forms three polymeric acids, cyanic, fulminic and cyanuric acids. But it is chiefly remarkable for forming with sulphur, and also with many metals, compound radicals, such as sulphocyanogen $Cy\,S_2 = Csy$, ferrocyanogen $Cy_3\,Fe = Cfy$ and others, all of which, like cyanogen itself, form acids with hydrogen, and salts with metals.

Hydrocyanic acid, H Cy = 27, is obtained by heating ferrocyanide of potassium with sulphuric acid and water. Ferrocyanide of potassium contains $Cy_3\,K_2\,Fe$, and when the acid acts on it, there are first formed cyanide of potassium and cyanide of iron, the latter separating as an insoluble powder, 2 K Cy + Fe Cy. The Fe Cy remain unchanged; but the 2 K Cy act on sulphuric acid, thus, $2\,K\,Cy + 2\,H, SO_4 = 2\,(K, SO_4) + 2\,H\,Cy$. The acid, H Cy, being volatile, distils over with water. It is obtained pure by adding chloride of calcium, which forms a heavy oily solution with the water, above which floats the pure dry acid, and may be drawn off by a pipette. It is very volatile, lighter than water, has a peculiar oppressive smell, and is very poisonous, even when smelled at, in its pure state. Before smelling it, it should be diluted. It is the well known poison prussic acid.

It is used in a diluted form in medicine, and the medicinal acid ought to contain in 100 parts not more than 3 of the pure acid. Its strength is ascertained by converting a measured portion into cyanide of silver, which is insoluble, and is formed on the addition of nitrate of silver, $H\,Cy + Ag\,O,\ NO_5 = HO,\ NO_5 + Ag\,Cy$. As the cyanide of silver, Ag Cy, weighs very nearly five times as much as the hydrocyanic acid, H Cy, for H Cy = 27 and Ag Cy = 134, we can easily ascertain the weight of the pure acid by dividing that of the cyanide of silver by 5.

The presence of hydrocyanic acid is detected by converting it into Prussian blue, which is done by adding, first potash, then mixed sulphate of protoxide and sesquioxide of iron, leaving an excess of potash, and after a few minutes adding lastly hydrochloric acid, which dissolves all but the Prussian blue. If the quantity of hydrocyanic acid be very small, the liquid, after adding the hydrochloric acid, must be allowed to stand for 24 hours, when the blue will appear at the bottom of the vessel.

Or the hydrocyanic acid may be converted into sulphocyanide of iron, which is of a deep blood-red colour. To do this, add to the diluted acid a little sulphuret of ammonium with a little sulphur, and evaporate to dryness in a water bath. To the dry mass which now contains sulphocyanide of ammonium, add a salt of sesquioxide of iron, and the red colour will appear.

The three compounds of cyanogen and oxygen are Cy O, HO, cyanic acid; $Cy_2\,O_2$, 2 HO, fulminic acid, and $Cy_3\,O_3$, 3 HO, cyanuric acid. The first and the last are both obtained from urea, and their relation to that compound and to each other is fully detailed under the head of polymerism and isomerism in organic compounds, and the transformations resulting from them. Fulminic acid, which is bibasic, and unknown in the free state, is obtained in combination with oxide of silver or oxide of mercury, forming the fulminating silver and fulminating mercury, the latter of which is the material used for percussion caps, by dissolving the metal in nitric acid and adding alcohol, when a very complex reaction occurs, and the fulminating salt is formed.

With sulphur, cyanogen forms a new compound radical sulphocyanogen, $Cy\,S_2 = Csy$, unknown in the free state. It is obtained as sulphocyanide of potassium, by melting ferrocyanide of potassium with sulphur, when each equivalent of K Cy takes up 2 eqs. of sulphur, forming the salt $K, Cy\,S_2 = K\,Csy$. This is purified by solution in alcohol. The radical forms also an acid with hydrogen, H, Csy, hydrosulphocyanic acid. This acid and its soluble salts are recognised by striking a deep red colour with salts of sesquioxide of iron.

With the metals, cyanogen forms salts very similar to the chlorides. The cyanides of potassium, silver, and mercury can hardly be distinguished from the corresponding chlorides.

But cyanogen is remarkable for forming with certain metals remarkable compound radicals, which are monobasic, bibasic, and tribasic. Thus we have—

Platinocyanogen,........	Pt Cy	=	Cpty monobasic.
Ferrocyanogen,.........	$Fe\,Cy_3$	=	Cfy bibasic.
Ferridcyanogen,......	$Fe_2\,Cy_6$	=	2 Cfy = Cfdy tribasic.

There are also cobaltocyanogen, $Co_2\,Cy_6$ tribasic, manganocyanogen, chromocyanogen, and iridiocyanogen, and two or three different platinocyanogens. Our space forbids us to enter into minute details, but we may state that 2 eqs. of ferrocyanide of potassium, $2\,Cy_3\,Fe,\ K_2 = Cy_6\,Fe_2',\ K_4$ when acted on by chlorine yield 1 eq. chloride of potassium, K Cl, and 1 eq. ferridcyanide of potassium $Cy_6\,Fe_2,\ K_3$. This is a beautiful red salt, also manufactured on the large scale. Prussian blue, a compound of cyanogen and iron, is formed either by the action of ferrocyanide of potassium on salts of sesquioxide of iron, or of ferridcyanide on salts of protoxide of iron. It is probable that there are more blue compounds than one, and that the ferrocyanogen being bibasic, forms a different compound from that produced by the tribasic ferridcyanogen. The reaction with the ferrocyanide is probably this:—

$$3\,Cfy,\ K_2 + 2\,Fe_2\,O_3 = 6\,KO + Cy_9\,Fe_7 = Fe_4\,Cfy_3$$

and with the ferridcyanide—

$$Cfdy,\ K_3 + 3\,FeO = 3\,KO + Cy_6\,Fe_5 = Cfdy\,Fe_3$$

But there is still some doubt as to the precise composition of the different forms of Prussian blue.

The variety of compound radicals formed by cyanogen, especially with iron and platinum, and the beauty of the salts thus formed, which generally crystallize with great facility, render these compounds very interesting. But it is in its relations to organic chemistry that cyanogen is most important, and we shall see, that in the decomposition of organic compounds containing nitrogen, compounds of cyanogen are constantly appearing, as well as compounds derived from them by transformation, such as urea. Cyanogen generally combines with the compound organic positive radicals, such as methyle, ethyle, benzoyle, and others. The most important of these compounds will be noticed in their proper place.

Carbon and Chlorine.

These elements do not directly combine; but when various organic compounds are exposed to the combined action of sun-light and chlorine, they are gradually destroyed, their hydrogen combining with chlorine, and finally their carbon also. There are two chlorides of carbon—$C_4\,Cl_4$, which has been called protochloride of carbon, a colourless liquid; and $C_4\,H_6$, which has been called sesquichloride of carbon, a crystalline solid. They are of no interest except as being the ultimate products of the substitution of chlorine for hydrogen in certain organic compounds.

The compounds of carbon with bromine and iodine are less known, but appear to be analogous to the chlorides. Carbon is not known to combine with fluorine.

9. *Sulphur.*

Symbol S. Equivalent = 16.

This element is found pure as a product of volcanic action, and vast quantities of it are exported from Ætna, Lipari, &c. It occurs also frequently in combination with metals forming sulphurets; the principal ores of lead, copper, bismuth, antimony, and mercury, are sulphurets; and those of iron, cobalt, nickel, zinc, cadmium, tin, arsenic, molybdenum, and silver, also occur. In combination with oxygen it is found as sulphuric acid, in gypsum or sulphate of lime, and in the sulphates of baryta, strontia, and lead.

Sulphur combined with hydrogen, or hydrosulphuric acid, is found in some mineral waters.

Sulphur is a solid of a peculiar pale yellow colour. It crystallizes easily when melted, and is found often finely crystallized. It melts about 245°, and when heated beyond 300° becomes thick and viscid, but beyond 500° it becomes again fluid, though less so than at first. At about 600° it boils, forming a brown vapour of specific gravity about 6650, which condenses on a cold surface or in water into a light powder, called flowers of sulphur. Heated in the air, it burns with a blue flame, producing a very suffocating gas, sulphurous acid. It is insoluble in water, sparingly soluble in boiling alcohol.

It exists, as has been already mentioned, in three different solid states or allotropic modifications; one in which it forms 4-sided prisms, when melted and allowed to cool; another when dissolved by the aid of heat in sulphuret of carbon, when it forms oblique octahedrons; and the third, when heated to 500° or 600° and thrown into water, when it forms a dark brown, transparent, amorphous, viscid mass, which may be drawn into threads. It is probable that there are three corresponding liquid states, the first fluid at 240° to 300°, the second viscid, from 350° to 500°, and the third again fluid, from 500° to 600°. There are probably also three forms of the gas or vapour, of different densities; at least this seems to be the case in some of its compounds.

Sulphur has a strong affinity for oxygen, but in regard to metals and hydrogen it has equally strong affinities, being negative to them, and analogous in its relations towards metals to both oxygen and chlorine.

The uses of sulphur, as a combustible for matches, as an ingredient in gunpowder, in the manufacture of sulphuric acid, and in medicine, are well known and important.

Sulphur and Oxygen.

These elements combine in several proportions, all the compounds being acids. But two of them are of special importance, sulphurous acid and sulphuric acid. We shall first, therefore, describe these, and then briefly notice the others.

1. *Sulphurous Acid,* $\dot{S}O_2 = 32$.

This is a gas, formed whenever sulphur burns in oxygen or in air. It is colourless, transparent, of a peculiar unpleasant taste and a most suffocating smell. Its specific gravity is 2·247 nearly. It is prepared also by heating sulphuric acid with copper filings, mercury, or charcoal. In each case the sulphuric acid, SO_3, loses 1 eq. oxygen, which

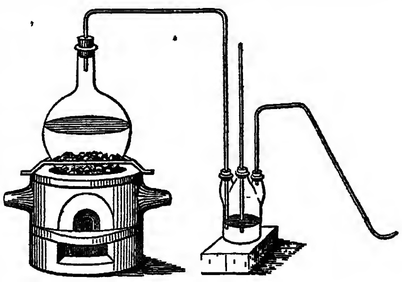

Fig 24.

unites with the metals or the carbon. In the case of copper we have, $2\,(HO, SO_3) + Cu = (Cu\,O, SO_3) + 2\,HO + SO_2$. With charcoal, $2\,(HO, SO_3) + C = 2\,SO_2 + 2HO + CO_2$. In the latter case, the gas is mixed with carbonic acid, and is therefore only proper for preparing the aqueous solution and the salts of sulphurous acid, the carbonic acid being excluded by the stronger sulphurous acid. Sulphurous acid gas must be collected over mercury—being absorbed by water, to which it communicates its suffocating odour.

The gas is easily liquefied by cold, under the ordinary pressure, and is kept in tubes hermetically sealed. It is a decided acid, forming salts with bases, and it has a peculiar action on vegetable blues, first reddening them, and then bleaching them. But the bleaching action differs from that of chlorine, for the colour is not destroyed, and may be restored, reddened of course, by stronger acids.

Sulphurous acid is characterized by its tendency to combine with a third equivalent of oxygen, and thus to be converted into sulphuric acid, which is manufactured in this manner, since sulphur does not combine directly with more than 2 eqs. of oxygen. The salts of this acid, sulphites as they are called, possess a considerable deoxidizing power, depriving many substances of oxygen, and being converted into sulphates.

Sulphurous acid is used in bleaching wool and silk, for which chlorine cannot be employed.

2. *Sulphuric Acid.*

a. *Anhydrous Acid,* $SO_3 = 40$.

Anhydrous or dry sulphuric acid is obtained by distilling the fuming or Nordhausen sulphuric acid, made by heating dried sulphate of iron. This fuming liquid is a compound or a mixture of anhydrous acid and of hydrated sulphuric acid, or oil of vitriol, which is the true active sulphuric acid; a gentle heat expels the anhydrous acid, which is very volatile, and collects in the receiver in the form of white crystals.

Anhydrous sulphuric acid is remarkable for its intense attraction for water. When thrown into water it hisses like red-hot iron, developing much heat, and forming oil of vitriol or hydrated acid. It is probably not a true acid, but readily passes into the true or hydrated form by the action of water. It melts at 68° and boils at 95°. It fumes strongly in the air, and attracts moisture with great rapidity. If a drop of water be allowed to fall into a bottle containing anhydrous sulphuric acid, there is a flash of light with explosion.

b. *Hydrated Sulphuric Acid,* HO, SO_3, or $H, SO_4 = 49$.

This, the true, active sulphuric acid, also called oil of vitriol, because it is obtained by distilling green vitriol or sulphate of iron, and has an oily consistence, is formed whenever the anhydrous acid comes in contact with water, $SO_3 + HO = HO, SO_3$. It was formerly made by distilling green vitriol or protosulphate of iron; the action of heat on that salt, dried at a moderate heat, so as to leave 1 eq. of water, is as follows: $Fe\,O, SO_3, HO = Fe\,O + HO, SO_3$. The protoxide of iron, $Fe\,O$, is oxidized into sesquioxide $Fe_2\,O_3$, at the expense of half of the sulphuric acid; thus $2\,Fe\,O + SO_3 = Fe_2\,O_3 + SO_2$; so that finally sesquioxide of iron is left, and sulphurous acid is given off with the oil of vitriol.

The modern manufacturing process is far more economical and productive. Sulphur is burned in air, with the help

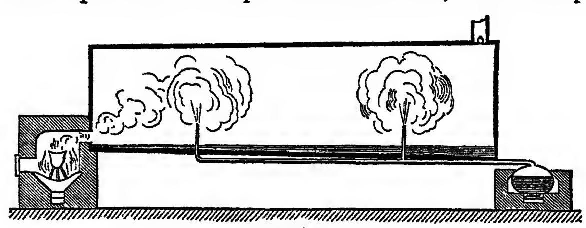

Fig. 25.

of a little nitre. The sulphurous acid gas thus formed is conducted into a large leaden chamber, where it meets with nitrous acid, obtained by the action of starch on nitric acid, and also with the vapour of water, introduced from a boiler. Water is also present on the floor of the chamber. The resulting action is rather complex. First, sulphurous acid, nitrous or hyponitrous acid, and water, combine to form the compound $2\,SO_2 + NO_4 + HO$. This compound forms crystals which fall down in a shower like snow, but are decomposed as soon as they touch the water on the floor, when the sulphurous acid is oxidized into sulphuric acid, and the nitrous or hyponitrous acid reduced to deutoxide of nitrogen; thus, $2\,SO_2, NO_4, HO = 2\,SO_3 + NO_2 + HO$. The

sulphuric acid dissolves in the water; the deutoxide of nitrogen rises into the air of the chamber, in which a continual current of air is kept up, and with the oxygen of the air again forms nitrous acid, which forms, with a fresh portion of sulphurous acid and water, the same crystalline compound as before. This is again decomposed by the water, and again deutoxide of nitrogen rises, again forms nitrous acid, and again the crystals are formed and decomposed, and so on, continuously. In this way, a comparatively small amount of deutoxide of nitrogen, supplied at first as nitrous acid, oxidizes an almost unlimited quantity of sulphurous acid, acting as a carrier of oxygen from the air to the sulphurous acid. It is only because a little of the deutoxide is unavoidably lost, being carried away with the current of effluent air, that a little nitrous acid must be added from time to time to the original supply. The regular supply of air and of steam is also essential.

After this process has been continued for some time, the water on the floor of the chamber is found so strongly charged with acid, that it no longer thoroughly decomposes the crystals. It is withdrawn and replaced by fresh water. The acid liquid, which is free from nitrous acid provided an excess of sulphurous acid has been present before drawing it off, contains only sulphuric acid and water, with perhaps a little sulphurous acid. It is boiled down in vessels of glass or of platinum, to expel superfluous water, till acid begins to rise in vapour. At this point, all the water has been expelled except the one equivalent, essential, either as water or by its elements, to the existence of the hydrated acid. The liquid now boils at nearly 600°, and has a specific gravity of 1845, and an oily consistence. When pure it is colourless, but the smallest trace of any organic matter such as wood, straw, or even dust, colours it brown. It is very acid and corrosive, and has a most powerful attraction for water, the mixture of it with water developing so much heat as to break the vessel if suddenly effected. This hydrated sulphuric acid or oil of vitriol is a true acid, and in all its relations exhibits the characters belonging to hydrochloric acid, which we have called the type of acids. Like it sulphuric acid with metals forms salts, disengaging hydrogen gas, and with metallic oxides, forms the same salts, water being separated. Hence, as formerly stated, although it contains the elements $SO_3 + HO$, and may without inconvenience be regarded as a hydrate of the anhydrous acid, it is still more probable that it is really a compound of hydrogen, H, SO_4, analogous in constitution to hydrochloric acid, HCl. All the phenomena which it exhibits with metals, oxides, &c. may be explained either way, but in the latter form its analogy with hydrochloric acid, so striking in the phenomena, becomes visible in the formula. Thus we have in the case of—

	Hydrochloric Acid.	Sulphuric Acid. 1	2	
Acids,	HCl	HO, SO_3	H, SO_4	or $H Su$
Salts,	MCl	MO, SO_3	M, SO_4	or $M Su$

The older formulæ in the second column indicate no analogy with hydrochloric acid and chlorides, but in the third and fourth columns this analogy is at once evident, especially in the fourth, where Su stands for SO_4, the hypothetical radical of sulphuric acid and sulphates. It must be borne in mind, however, that the body SO_4 is hypothetical and has not been proved to exist. Yet the assumption of it is generally agreed on, since it brings into one category hydrochloric acid and sulphuric acid with their respective congeners, otherwise separated. On this supposition the action of sulphuric acid on a metal and on a metallic oxide is as follows, which agrees perfectly with the action of hydrochloric acid:—

On a metal, $M + H, SO_4 = M, SO_4 + H$
On an oxide, $MO + H, SO_4 = M, SO_4 + HO$

In both cases, the metal simply replaces the hydrogen, and this is true of the older view also, for in that we have—

With metal, $M + HO, SO_3 = MO, SO_3 + H$
With oxide, $MO + HO, SO_3 = MO, SO_3 + HO$

We have explained this fully, because the same views apply to all hydrated acids.

Sulphuric acid forms salts with all bases, several of which occur in nature, as sulphate of lime, of baryta, of strontia, of magnesia, of lead. With 1 eq. of water it forms a hydrate, which crystallizes in cold weather. It also forms another hydrate with 2 eqs. of water, which does not crystallize so easily.

The acid is recognised by forming with baryta, whenever they meet in any mixture, the sulphate of baryta, absolutely insoluble, not only in water but also in nitric and hydrochloric acids, which dissolve many compounds of baryta insoluble in water. Any sulphate, moreover, if heated to redness with charcoal, yields, on the addition of water and acids, the odour of sulphuretted hydrogen.

The uses of sulphuric acid are numerous and important. It is employed in the manufacture of soda, bleaching powder, nitric acid, hydrochloric or muriatic acid, acetic acid, ether, alum, Epsom salt, in dissolving bone earth for agricultural purposes, in charging galvanic batteries for the electrotype and telegraph, and lastly, in medicine and pharmacy. When we consider that many other arts and manufactures depend on these—as for example, the making of glass and of soap, on the manufacture of soda—we shall see that the value of sulphuric acid cannot be over-estimated, and that every improvement in its preparation, or everything that renders it cheaper, will create new manufactures and new arts hereafter, as has already occurred. It is impossible to calculate what might be the effect, for example, of a great reduction in the price of sulphur, for which substance we are dependent on Sicily, and whose cheapness at present enables us to obtain sulphuric acid at a mere fraction of its former price. Such a reduction would not only cheapen sulphuric acid, but also soda, bleaching powder, glass, soap, and many other articles, and through these a multitude of products connected with them. A rise in the price of sulphur, or an interruption in the supply, such as was threatened some years ago, would have a most disastrous effect, through its influence on the price of sulphuric acid.

3. *Hyposulphurous Acid*, $S_2 O_2 = 48$.

This acid is hardly known in the uncombined state, as it speedily undergoes decomposition. But its salts are permanent. They are formed by boiling the salts of sulphurous acid with sulphur, when 1 eq. of sulphur is taken up by 1 eq. sulphurous acid. Thus, taking sulphite of soda, $Na O, SO_2 + S = Na O, S_2 O_2$. Hyposulphite of soda thus formed, crystallizes readily in large transparent prisms. It will be seen that this acid contains sulphur and oxygen in the proportion of 1 eq. of each. But we adopt the formula $S_2 O_2$ instead of SO, because, in the neutral salts, 1 eq. of the base is neutralized by $S_2 O_2 = 48$, and not by $SO = 24$. The acid may be viewed either as directly formed of S_2 and O_2, or as composed of sulphurous acid and sulphur, $SO_2 + S$. The latter may probably be true, as there are several acids apparently of analogous constitution.

The most remarkable character of this acid, or rather of its salts is their power of dissolving the compounds of silver which are insoluble in water and in strong acids, such as chloride, bromide, iodide, &c. of silver. The solution thus obtained has a most intensely sweet taste, followed by a metallic aftertaste. On account of this solvent power, hyposulphite of soda is much used in photography, to fix the image by removing the compound of silver unacted on by light, which if left would be acted on and destroy the pictures.

4. *Hyposulphuric Acid.* $S_2O_5 = 72$.

This acid is more permanent. It is formed when sulphurous acid is made to act on peroxide of manganese, a portion of the acid being oxidized to sulphuric acid, which with another portion of sulphurous acid forms the new acid, for $SO_3 + SO_2 = S_2O_5$. The acid thus formed combines with the protoxide of manganese. The action is as follows:—$2\ SO_2 + Mn\ O_2 = Mn\ O, S_2O_5$. From the salt of manganese, others may be obtained, and from the hyposulphate of baryta, the base being removed by sulphuric acid, the acid is obtained. It is sour and tolerably permanent, unless strongly heated, but of little interest hitherto.

There are still three acids formed of sulphur and oxygen. They all contain, like the last-named acid, 5 eqs. of oxygen, with regularly increasing quantities of sulphur, and their names and formulæ are—

5. Monosulphuretted hyposulphuric acid, $S_3O_5 = 88$
6. Bisulphuretted hyposulphuric acid, $S_4O_5 = 104$
7. Tersulphuretted hyposulphuric acid, $S_5O_5 = 120$

They all form crystallizable salts with baryta, and may be obtained from these by means of sulphuric acid, which precipitates the baryta. They are sour, and easily decomposed, yielding sulphuric acid, sulphurous acid, and sulphur. They very much resemble one another, and are of no practical interest, so that we shall not describe their preparation. It is remarkable that the third of them is polymeric with hyposulphurous acid, but the two acids are quite distinct; for not only can the acid S_5O_5 be obtained in solution, while the acid S_2O_2 is not known in a separate state, but they neutralize totally different weights of the same bases, or equal weights of the base require different weights of the two acids, in the proportion of 120 to 48.

Sulphur and Hydrogen.

These elements form two compounds, one of which is of great importance to the chemist. It is—

1. *Hydrosulphuric Acid,* $HS = 17$.

This compound, called also sulphuretted hydrogen, is a gas which sometimes occurs in volcanic districts, and is frequently found dissolved in mineral waters. It is formed during the putrefaction of organic matters containing sulphur, such as albumen in eggs, &c.

It is procured by the action of acids on sulphuret of iron; thus, with sulphuric acid, $Fe\ S + H, SO_4 = Fe, SO_4 + HS$; and with hydrochloric acid, $Fe\ S + H\ Cl = Fe\ Cl + HS$. It is also produced by the action of hydrochloric acid on tersulphuret of antimony, $Sb\ S_3 + 3\ H\ Cl = Sb\ Cl_3 + 3\ HS$. It may be collected over warm water or brine; cold water absorbs it.

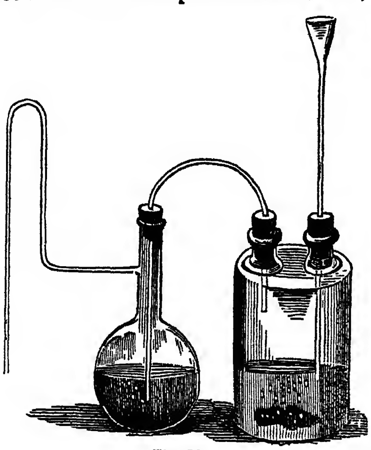

Fig. 26.

It is transparent, inflammable, burning with a pale blue flame, and depositing sulphur. It has a most offensive smell, that in fact of putrid eggs, which yield it, and this smell it communicates with its sulphureous taste to water, as in the water of Harrowgate. It also blackens the salts of lead and of many other metals, forming sulphurets of the metals. The action with a salt of lead is as follows:—if we suppose the lead to be present as oxide, the acid may be left out of view; $Pb\ O + HS = HO + Pb\ S$. It is the same whether the lead be present as chloride, $Pb\ Cl$, or as sulphate, $Pb\ O, SO_3$, or Pb, SO_4, or as carbonate, $Pb\ O, CO_2$.

It is this action of hydrosulphuric acid on metals and their salts which renders it so valuable as a test; for as the sulphurets of the heavy metals are insoluble in water, and usually of dark colours, it enables us to detect a very small quantity of those metals on the solutions of which it acts, and even to distinguish many of them by the colour of the precipitate. The salts of lead, copper, mercury, silver, gold, bismuth, and some others, form dark brown or black sulphurets; protosalts of tin give a chestnut brown; antimony, an orange-brown; persalts of tin, a dirty-yellow; arsenic and cadmium, a bright yellow, with this gas.

The solution of the gas reddens vegetable blues, but as in the case of carbonic acid, on standing or on boiling the blue colour returns.

The gas is liquefied by a powerful pressure. It is highly poisonous when inhaled, and has often caused fatal accidents in graves, when, a neighbouring coffin being perforated by the pickaxe, the gas rushes out and fills the grave striking down the gravedigger like lightning. The same thing happens in the large cloacæ of great cities. It is said that a horse whose head is in pure air, while his body is inclosed in an atmosphere containing only $\frac{1}{800}$th of its volume of the gas, is soon killed by the gas absorbed through the skin. Taken internally, it is not only safe, but a useful remedy.

2. *Bisulphuret of Hydrogen,* $HS_2 = 33$.

This compound is formed when lime and sulphur are boiled with water, till a deep yellow solution is formed. This is then poured into hydrochloric acid of moderate strength. The liquid becomes milky, and on standing deposits the bisulphuret as a heavy oily liquid, which may be withdrawn by a pipette. It undergoes spontaneous decomposition, which is hastened by the presence of metallic oxides. In these characters, and in its composition, it is analogous to the deutoxide of hydrogen. It has a pungent and offensive smell. When sealed up in one end of a bent tube, and left to itself, it is gradually resolved into sulphuric and hydrosulphuric acid, and the latter is liquefied at last by its own pressure.

There is said to be a compound of sulphur and nitrogen, $N\ S_3$, a yellowish white powder. But this is doubtful.

Sulphur and Chlorine.

When dry chlorine is passed over sulphur they readily unite and form two compounds, both liquid, volatile, and pungent. One is S_2Cl, subchloride or dichloride of sulphur, a dense yellow liquid of specific gravity 1687, boiling at 280°. The other is $S\ Cl$, protochloride of sulphur, a red liquid, of specific gravity 1620, boiling at 150°. Both decompose water, forming hydrochloric, sulphuric, and sulphurous acids.

When sulphur and iodine are heated together, they melt and form a black crystalline mass on cooling. It cannot be distilled, heat decomposing it, and its precise composition is unknown. Nothing is known of the compounds of bromine and sulphur, nor of those of fluorine with sulphur.

Sulphur and Carbon.

When the vapour of sulphur is made to pass over charcoal at a red-heat, a compound is formed which passes over and is collected in water where it sinks as a heavy liquid to the bottom. To purify it from a little sulphur that distils along with it, it is distilled again at a gentle heat. Its composition is $C\ S_2$, bisulphuret of carbon.

It is a very mobile, transparent, colourless liquid, refract ing light strongly, of a very peculiar odour, like that of decaying cabbage or horse-radish, very inflammable. Its specific gravity is 1293, and it boils at 118°.

Bisulphuret of carbon is a powerful solvent for many substances insoluble in water or alcohol; such as phosphorus, sulphur (which crystallizes beautifully from the solution), resins; and even such bodies as caoutchouc and gutta percha are softened if not dissolved by it. It is now manufactured on the large scale, and is used in making varnishes and certain preparations of caoutchouc.

10. *Selenium.*

Symbol Se. Equivalent = 39·5.

This element is so closely analogous to sulphur, that a very brief account of it will suffice. It occurs in nature chiefly as seleniuret of lead, a rare mineral. Some kinds of iron pyrites contain a little seleniuret of iron, or at all events a compound of selenium; and when sulphur made from such pyrites is converted into sulphuric acid, there is found in the leaden chambers a deposit consisting of sulphur, several metals, such as copper, lead, and arsenic, and selenium. From this deposit, or from the native seleniuret of lead, selenium is prepared. It is first dissolved in the form of selenious acid, and this is deoxidized by sulphurous acid, when the selenium separates as a deep red powder. At 392° it melts, forming a brown liquid, which boils at about 1290°, and yields a deep yellow gas. On cooling, the liquid first becomes viscid and tenacious, and finally consolidates to a nearly black solid mass, which in thin layers is translucent and red, and has a metallic lustre. When sublimed, the vapour condenses on a cold surface into a powder of a fine red, similar to the precipitated selenium.

In all its chemical relations selenium resembles sulphur, only that it is denser, its specific gravity being 4280 in the mass and 4800 in the powder; and less volatile. Its affinities are also less powerful.

Selenium appears to form three compounds with oxygen, namely, the oxide of selenium, a gas, the composition of which is not known, selenious acid $Se\,O_2$, and selenic acid $Se\,O_3$.

Heated in air, selenium burns with a pure blue flame, producing a very penetrating and peculiar odour, compared to that of putrid horse-radish. This belongs to the oxide, which has not been obtained in a state of purity. A very minute trace of selenium may be detected before the blowpipe by this character. The gas appears to be poisonous.

Selenious acid, SeO_2, is the chief product of the combustion of selenium, and if the operation is conducted in oxygen in a proper apparatus, the acid collects in the cold part of it in colourless crystals, very soluble in water. This acid is also formed when selenium is oxidized by nitric or by nitro-hydrochloric acids. Selenious acid is deprived of its oxygen by many substances, such as iron, zinc, or sulphurous acid, when the selenium is deposited as a cinnabar red powder. The vapour of the acid is yellow.

Selenic acid, $Se\,O_3$, or, in the state of hydrate, $HO, Se\,O_3 = H, Se\,O_4$, is entirely analogous to sulphuric acid in properties. It is obtained in combination with oxide of lead, by heating seleniuret of lead with nitrate of potash; or by first heating selenium with that salt, which forms seleniate of potash, and then adding to the solution of the potash salt a salt of lead, when seleniate of lead is precipitated. This salt, $Pb\,O, Se\,O_3$, is decomposed by hydrosulphuric acid as follows; $Pb\,O, Se\,O_3 + HS = Pb\,S + HO, Se\,O_3$; thus yielding the hydrated acid. The anhydrous selenic acid is unknown.

The salts of selenic acid are in form and properties so exactly similar to those of sulphuric acid, as only to be distinguishable from them by analysis.

With hydrogen, selenium forms a gaseous acid, hydroselenic acid, $H\,Se$, of a most fetid odour, and still more poisonous than hydrosulphuric acid. It is obtained, like hydrosulphuric acid, by the action of hydrochloric acid on a compound of iron with selenium. $H\,Cl + Fe\,Se = Fe\,Cl + H\,Se$. This gas is soluble in water, and acts on metallic solutions in the same way as hydrosulphuric acid, only forming seleniurets instead of sulphurets. $MO + H\,Se = HO + M\,Se$, is a general equation representing the action of hydroselenic acid on metallic protoxides.

Like sulphur, selenium combines directly with metals, when heated with them.

From its great rarity, selenium is not applied, either itself or in its compounds, to any useful purpose. It is probable, however, that some of its compounds, from their energetic action on the system, may prove valuable remedies.

The metallic lustre of compact selenium has led some to class it with metals. But it is a nonconductor of heat and electricity, and so analogous to sulphur, that these elements must be considered together. A third substance belongs to the same group by its chemical relations, namely tellurium; but that element has the conducting power as well as the lustre of metals, and it is regarded as a metal.

11. *Phosphorus.*

Symbol P. Equivalent = 32.

This element is found chiefly in the animal kingdom, in bones, as phosphoric acid united to lime and a little magnesia. But all the phosphate of lime, or bone earth of animals, is derived from their food, and consequently from the soil. In fact, all fertile soils contain this phosphate in small but essential quantity. Without it, although all the other elements of plants were present, no plant could grow. Phosphate of lime is found in minute crystals scattered through all rocks, and there are occasionally beds containing large quantities of bone earth, derived from the bones of extinct animals; as the osteolite of the Rhine, and the so-called coprolite beds in the Suffolk Crag. Phosphoric acid also occurs sparingly, combined with the oxides of lead, copper, uranium, and iron.

Phosphorus is obtained from bones, by first burning them to destroy the animal matter. The bone earth is next bruised, and digested with sulphuric acid and water till all coarse grains have disappeared, and a uniform fine powder, sulphate of lime, is formed. The water now holds in solution acid phosphate of lime. This is filtered from the sulphate, evaporated to the consistence of a syrup, mixed with charcoal, and exposed to a white heat in a retort. The charcoal deprives the phosphoric acid of oxygen, and while carbonic acid escapes, phosphorus distils over, and is collected under water. To purify it, it is melted under water and squeezed through leather. It is then, if necessary, redistilled by itself, and kept under water.

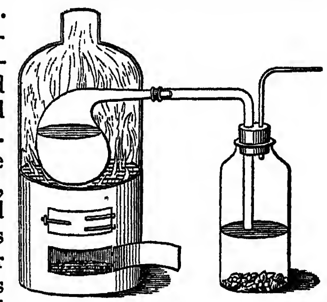

Fig. 27.

It is a solid, nearly colourless, translucent, of the consistence of wax, fusible a little above 100°, and taking fire in air at that temperature. It boils at 550°. The specific gravity of phosphorus is 1770, water = 1000. That of its vapour is 4326, air = 1000.

It is distinguished by its inflammability, which is such, that if exposed, dry, to air, in warm weather, it often takes fire spontaneously, and is therefore kept under water. When exposed to light, it becomes opaque externally, and the change spreads gradually inwards.

When heated, it burns with great splendour, whether in air or oxygen, especially in the latter; in burning, it forms phosphoric acid, which, if no moisture be present, condenses to a white powder like snow.

When phosphorus is heated for some time short of its boiling point, between 445° and 480°, it becomes dark

red, comparatively infusible, far less inflammable, and insoluble in sulphuret of carbon, which dissolves ordinary phosphorus. The red modification does not melt nor take fire, even at 480°. At about 500° it passes into ordinary phosphorus. This is a most remarkable instance of allotropic modification of an element, which in these two states exhibits properties, both physical and chemical, more different than are those of many different elements. Yet the one form passes into the other, and both yield the same compounds.

Phosphorus and Oxygen.

The affinity of phosphorus for oxygen is very strong, so that even at ordinary temperatures it is slowly oxidized in the air, becoming luminous in the dark. The temperature also rises slightly, and in summer the oxidation is thereby so much accelerated that heat enough is evolved to melt and set fire to the phosphorus. This is a true case of spontaneous combustion, and illustrates the occurrence of that phenomenon in powdered charcoal, or in porous bodies moistened with oil. At any season it may be illustrated in phosphorus, by allowing a few drops of a solution of phosphorus in bisulphuret of carbon to dry up on blotting paper, on which it leaves a film of finely divided phosphorus. This very soon begins to oxidize, vapours rise from it luminous in the dark, it gradually becomes warm, and in a few minutes bursts into flame. It has recently been proved by Schönbein that phosphorus in air first causes the formation of ozone, which is an allotropic form of oxygen, and possibly also of a hydrate of this substance, having the composition $HO_3 = O_2 + HO$. Both of these forms of ozone are much more powerful oxidizing agents than ordinary oxygen, and it appears that it is ozone which really oxidizes phosphorus, when exposed to air till the temperature rises so high as to cause combustion.

1. *Phosphorous Acid*, $PO_3 = 56$.

This acid is formed when phosphorus undergoes slow oxidation. It is best obtained pure by the action of water on terchloride of phosphorus, $P\,Cl_3 + 3\,HO = 3\,H\,Cl + PO_3$. It is very soluble and sour, and may be obtained in a mass of deliquescent crystals of the hydrated acid, PO_3, 3 HO. When heated, it yields phosphuretted hydrogen gas, while phosphoric acid is left; thus, $4\,PO_3 + 3\,HO = 3\,PO_5 + PH_3$. Phosphorous acid is not of much importance. It tends, by combining with 2 eqs. of oxygen, to form phosphoric acid.

2. *Phosphoric Acid.*

a. *Anhydrous Phosphoric Acid*, $PO_5 = 72$.

This compound is formed when phosphorus is burned in dry air or oxygen, and appears as a snow-white substance,

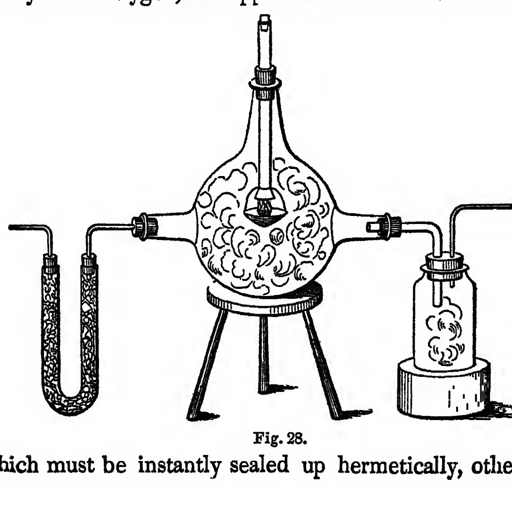

Fig. 28.

which must be instantly sealed up hermetically, otherwise it attracts moisture from the air, and deliquesces into the monobasic hydrated acid, PO_5, HO.

It is doubtful whether the anhydrous acid be really an acid. It cannot be tasted without bringing it in contact with water on the tongue, when it instantly forms the hydrated or true acid. It is used in research on account of its tendency to abstract the elements of water from many organic substances, without charring them as sulphuric acid does.

b. *Hydrated Phosphoric Acid.*

1st, *Monobasic*, PO_5, HO or PO_6, $H = 81$.

This acid is formed when the anhydrous acid acts on water. It is apt to pass into the bibasic and tribasic forms, by taking up more water, but is again obtained pure by heating to low redness, when the monobasic acid is left. It is very sour, coagulates albumen, and causes a white precipitate in nitrate of silver, the monobasic phosphate of silver, PO_5, Ag O or PO_6, Ag. It forms only one series of salts, containing one eq. of base or of metal, hence its name. Its solution passes, slowly in the cold, rapidly when heated, first into the bibasic, and then into the tribasic form.

2d, *Bibasic Phosphoric Acid*, PO_5, 2 HO or PO_7, $H_2 = 90$.

This acid is obtained by heating the solution of the tribasic or common phosphoric acid till only 2 eqs. of water are left, or by decomposing bibasic phosphate of lead or silver by hydrosulphuric acid. Its solution is not permanent, passing into the tribasic acid. But its salts are quite permanent. It does not coagulate albumen, nor precipitate nitrate of silver, unless ammonia or some base be added, when it forms a white bibasic phosphate of silver, quite different from the monobasic salt. It forms two series of salts, those with two eqs. of fixed base, such as bibasic phosphate of soda, PO_5 2 Na O or PO_7, Na_2, and those with 1 eq. of fixed base, and 1 eq. of basic water, as the acid bibasic phosphate of soda, PO_5, Na O, HO or PO_7, Na H.

3d, *Tribasic Phosphoric Acid*, PO_5, 3 HO or PO_8, $H_3 = 99$.

This is the common form of phosphoric acid, as the others, by taking up water, pass into it. It does not coagulate albumen, nor precipitate nitrate of silver, till some base is added, when it forms a lemon-yellow precipitate of tribasic phosphate of silver, PO_5, 3 Ag O or PO_8, Ag_3. It forms 3 series of salts, with 3 eqs. of fixed base, as the salt of silver just named; with 2 of fixed base and 1 of water, as in common phosphate of soda, PO_5, 2 Na O, HO or PO_8, Na_2, H; and with 1 eq. of fixed base and 2 of water, as the acid phosphate of potash, PO_5, KO, 2 HO or PO_8, K, H_2. This is the form of the acid existing in bones, and in the mineral kingdom.

It will be seen, that if we regard these acids as hydrates or compounds of water with dry acid, they all contain the same acid, and differ only in water. This is possible, for in sulphuric acid we have oil of vitriol, SO_3, HO, the hydrate SO_3, 2 HO, and the hydrate SO_3, 3 HO, all of which undoubtedly contain the same acid, and yield the same salts with bases, namely, sulphates, of which there is but one class or series.

But the three phosphoric acids differ far more than is accounted for by mere differences in the proportion of water, as in their action on albumen, and on nitrate of silver, and above all, in forming salts entirely distinct, which are monobasic, bibasic, and tribasic, that is, contain 1, 2, or 3 eqs. of base, fixed or otherwise. Nothing of all this occurs in the different hydrates of sulphuric acid, the first of which is the true acid, H, SO_4, as already explained, the other two compounds of this with water, H, SO_4 + HO and H, SO_4 + 2 HO. But this water in these two compounds is not basic, and is not replaceable by bases.

What is the cause of this difference between sulphuric

and phosphoric acid? It is not enough to say, that when the dry acid is combined with 1, 2, or 3 eqs. of water, it is disposed to take up 1, 2, or 3 eqs. of base. That is the fact to be explained, and not an explanation of it. Sulphuric acid exhibits no such tendency when combined with 2 or 3 eqs. of water, and we can hardly suppose the three phosphoric acids to contain the same acid.

Now, here the hydrogen theory of acids comes to our aid. According to it, the first hydrate is PO_6, H like nitric acid, NO_6, H. It takes 1 eq. of base to form neutral salts, because it contains 1 eq. of replaceable hydrogen, as sulphuric and nitric acids do.

The second hydrate is PO_7, H_2. Here the radical is different, and as there are 2 eqs. of replaceable hydrogen, it takes 2 eqs. of base to form neutral salts. And there are two series of these, according as half or the whole of the hydrogen is replaced by metals.

The third hydrate, in like manner, is PO_8, H_3, with a different radical, and requiring 3 eqs. of base for the 3 eqs. of replaceable hydrogen, forming also 3 series of salts, according as the hydrogen is partially or entirely replaced by metals.

On this view, the three acids must be different, whereas, on the other, they ought to be the same, as in sulphuric acid. We see also why they form different salts, and why the first can form only one series, the second two, and the third three series of salts.

Phosphoric acid as such is not much used nor of much interest, but its salts, especially those of the tribasic modification, are of the utmost and most essential importance. The earth of bones is essentially a tribasic phosphate of lime; the principal salt in the blood, to which it owes its alkaline reaction, and its peculiar power of absorbing and of giving off carbonic acid, is a tribasic phosphate of soda, with 2 eqs. of fixed base and 1 eq. of basic water, PO_5, 2 NaO, HO, or PO_8, Na_2 H, and the chief salt in the juice of flesh, and in the gastric juice, that which gives the acid reaction to these fluids, is a tribasic phosphate of potash, with 1 eq. of fixed base and 2 eqs. of basic water, PO_5, KO, 2 HO, or PO_8, K, H_2. Since these peculiar phosphates have undoubtedly each its own peculiar function to perform in the animal economy, we see how important it is to study the most minute and apparently trifling peculiarities of such a compound as tribasic phosphoric acid; although these very researches, when first made, were regarded as scientific curiosities of no practical value. No one could have conjectured that it would ever be important to know that tribasic phosphoric acid with soda tends to form a salt with 2 eqs. of fixed base, of alkaline properties, though its composition is that of an acid salt, while the same acid with potash forms by preference a salt with 1 eq. of fixed base which is strongly acid, while yet the acid can form two other compounds with each alkali. Yet we now see that such apparently insignificant facts are closely connected with the due performance of the most essential vital functions. In hundreds of cases we can substitute potash for soda, and obtain the same results, but potash cannot replace the soda of the phosphate in the blood, nor soda the potash of that in the juice of flesh.

3. *Hypophosphorous Acid*, $PO = 40$.

This acid is formed when phosphorus is boiled with bases, such as lime or potash. Phosphoric acid and phosphuretted hydrogen are formed at the same time, as will be shown under phosphuretted hydrogen, and the two acids both combine with the base. The phosphate of lime is insoluble, the hypophosphite soluble. The acid is little known, but has a tendency to absorb oxygen and pass into phosphoric acid.

Phosphorus and Hydrogen.

1. *Phosphuretted Hydrogen Gas.* $PH_3 = 35$.

This compound is formed when phosphorus is boiled with lime and water, or potash and water. The precise nature of the reaction is not ascertained, so as to enable us to represent it in an equation; but water is decomposed, and while its oxygen unites with one portion of phosphorus to form hypophosphorous acid, and apparently with another to form phosphoric acid, its hydrogen combines with a third portion, forming the new compound, which is given off in the form of a gas, not absorbed by water.

It is highly inflammable, and when prepared as above takes fire spontaneously in contact with air. But this property is owing to the presence of a minute quantity of another compound of the same elements, the liquid phosphuretted hydrogen; and when this is removed, the gas is no longer spontaneously inflammable, though still taking fire when slightly heated in air. The spontaneously inflammable gas loses that property by standing over water, when it deposits a little of a solid phosphuretted hydrogen, formed from the liquid one.

Each bubble of the spontaneously inflammable gas, as it rises through the water, takes fire, and forms a beautiful ring of white vapour (water and phosphoric acid), which expands as it ascends. Bubbles of the gas, allowed to enter a vessel of oxygen, produce each of them a slight explosion and a brilliant flash of light, but care must be taken that only one bubble at a time enters the oxygen, otherwise dangerous explosions may occur. The gas may also be prepared by the action of phosphuret of calcium on water.

When phosphuret of calcium is acted on by dilute-hydrochloric acid, or when phosphorus is boiled with an alcoholic solution of potash, the pure gas is formed, not spontaneously inflammable. All substances which destroy the liquid phosphuretted hydrogen, such as alcohol, ether, and volatile oils, deprive the spontaneously combustible gas of that property. And the addition of a minute trace of the liquid compound to the non-spontaneously inflammable gas renders it at once spontaneously inflammable.

2. *Liquid Phosphuretted Hydrogen,* $PH_2 = 34$.

When the spontaneously inflammable gas is passed through a U-shaped tube surrounded by a freezing mixture, it deposits water which freezes, and a small quantity of the liquid compound, PH_2. The gas has now lost its spontaneous inflammability. The liquid instantly takes fire in contact with air or oxygen. When kept the liquid is resolved into the gas PH_3, and a solid compound P_2 H, thus, $5\ PH_2 = 3\ PH_3 + P_2\ H$.

3. *Solid Phosphuretted Hydrogen,* $P_2\ H = 65$.

The formation of this compound from the liquid one has just been explained. It is deposited from the spontaneously inflammable gas when kept over water, as an orange-coloured film.

It should be mentioned that the gas, PH_3, has a composition analogous to that of ammonia, NH_3, and that it has also some analogy in properties. Thus it seems to be a weak base, and with hydriodic acid it forms a saline compound crystallizing in cubes, like the hydriodate of ammonia. The phosphuretted hydrogen also, like ammonia, admits of the replacement of its hydrogen by such radicals as methyle and ethyle, forming volatile bases, analogous to the volatile organic bases derived from ammonia.

With nitrogen phosphorus forms a compound, PN_2, a white solid, which resists a red heat and the action of the strongest acids.

Phosphorus and Chlorine.

1. *Terchloride of Phosphorus,* $P\ Cl_3 = 138{\cdot}5$.

When chlorine comes in contact with phosphorus, the latter takes fire, and they combine. If the phosphorus be in excess, we obtain a colourless liquid, $P\ Cl_3$. It is pungent, fuming, of specific gravity 1450. When mixed with

water it sinks to the bottom, and there is rapidly dissolved, heat being developed. The action is as follows: $PCl_3+3HO=3HCl+PO_3$. The hydrochloric acid dissolves in the water along with the phosphorous acid, but may be expelled by a gentle heat, and hydrated phosphorous acid is left.

2. *Perchloride of Phosphorus.* $PCl_5=209\cdot5$.

When the chlorine is in excess, or when chlorine is passed through the last compound, there is formed the solid perchloride, PCl_5. This also decomposes water, as follows: $PCl_5+5HO=5HCl+PO_5$, yielding, therefore, hydrochloric and phosphoric acids.

Perchloride of phosphorus has of late been employed as an agent of research in organic chemistry. By its means, certain anhydrous organic acids, previously unknown, have been obtained, and much light thrown on the constitution of organic acids.

Phosphorus combines instantly with iodine, heat and light being evolved. The compounds are of a dark red or brown colour, and solid. They decompose water exactly as the chlorides do. It is probable that there are two iodides, PI_3 and PI_5, corresponding to the chlorides, but the former alone has been analysed, and another iodide, PI_2, has also been obtained. These two compounds may be had in orange and in dark red crystals by dissolving phosphorus and iodine in bisulphuret of carbon, and applying artificial cold.

Bromine acts very violently on phosphorus, and seems to form bromides corresponding to the chlorides.

No compounds are known of phosphorus with fluorine or carbon.

With sulphur, phosphorus readily combines in several proportions. The compounds are not only highly inflammable, but liable to explode with great violence when slightly warmed, and sometimes even spontaneously. Hence they are very dangerous, and must be very cautiously experimented with. Berzelius, who examined them, narrowly escaped from some frightful explosions, occurring quite unexpectedly. Some of them are liquid, others solid; and it appears that the different allotropic states of both the elements are seen also in these compounds, several of which are isomeric. As these compounds are not fully understood, and are for the present of no practical importance, we shall not enter into details in regard to them.

12. *Boron.*

Symbol B. Equivalent = 10 9.

This element is found in nature combined with oxygen, as boracic acid, which occurs free, dissolved in the vapours of certain volcanic districts in Tuscany. The hot vapours are received in reservoirs of water, in which the acid dissolves, and the heat of the vapours is employed to evaporate the water, till at last the acid crystallizes nearly pure. In Thibet boracic acid occurs in the soil near certain lakes, combined with soda, forming the crude borax of commerce, which is purified from the peculiar fatty matter it contains by a secret process known only to the Dutch. Borax is now largely manufactured in England, from the boracic acid of Tuscany, and of the volcanic islands of the Mediterranean.

Boron is obtained by heating dry boracic acid with potassium, $4BO_3+K_3=3(KO,BO_3)+B$. Water dissolves the borate of potash, and leaves the boron as a dark brown infusible powder, which, when heated to redness in oxygen, burns and reproduces boracic acid.

Boracic Acid, $BO_3=34\cdot9$.

Obtained as above described, and purified by repeated crystallization, or from borax (biborate of soda) by the addition of sulphuric acid to a hot saturated solution, forms white scaly crystals, composed of the anhydrous acid and water, $BO_3, 3HO$. When heated the crystals melt, lose their water, and at a red heat leave the anhydrous acid perfectly fluid, which on cooling forms a transparent glass. This soon becomes opaque by attracting water from the air. The acid is very soluble in hot, sparingly soluble in cold water. It is a weak acid at ordinary temperatures, but at a red heat it expels all less fixed acids. It gives to all its compounds a peculiar tendency to melt when heated, and hence borax is much used as a flux in metallurgical operations on the small scale. Boracic acid, and the compounds of boron in general, colour flame green, and by this character the presence of boracic acid has been detected in various minerals in which it is present in small quantity, as in tourmaline and schorl, &c. Boracite and datholite contain boracic acid in larger proportion. There is no other compound of boron and oxygen.

With chlorine boron forms a gaseous compound, the terchloride, BCl_3, corresponding to boracic acid, which decomposes water, yielding boracic and hydrochloric acids, $BCl_3+3HO=3HCl+BO_3$.

With fluorine it forms a similar gas, terfluoride of boron, BF_3, which fumes strongly in moist air. Its action on water is as follows: $3BF_3+3HO=(3HF, 2BF_3)+BO_3$. The compound $3HF, 2BF_3$ is called hydrofluoboric acid.

With nitrogen boron is said to form a white solid compound, BN, which is very stable. When fused with hydrate of potash it is converted into boracic acid and ammonia, the latter being expelled, while the former combines with the potash. $BN+3KO,HO=KO,BO_3+2KO+NH_3$.

The chief uses of boracic acid are as a flux, both in itself and in the form of borax; and the latter substance is also used in medicine. Goldsmiths use borax to clean the surface of gold, silver, and other metals which are to be soldered together. Borax is sprinkled on the metal, and melted by the blowpipe, when it dissolves any oxide or other impurities, leaving a bright metallic surface.

13. *Silicon or Silicium.*

Symbol Si. Equivalent = 21·3.

Next to oxygen, this is perhaps the most abundant element. Its only oxide, silicic acid or silica, constitutes, whether free or combined, by far the greater part of all rocks and soils, excepting only the different forms of limestone, marble, and chalk, gypsum, and rock salt.

Silicon is obtained by the action of potassium on a compound of fluorine, silicon, and potassium; and appears, like boron, in the form of a dark brown powder, which, strongly heated in oxygen, burns with a brilliant light, and is converted into silicic acid. It has recently been stated that, by means of a galvanic current, silicon has been deposited on the surface of metals, and exhibits a bright metallic lustre. This requires confirmation.

Silicon and Oxygen. $SiO_3=45\cdot3$.

This, the most abundant of all minerals, occurs pure in the form of rock crystal and quartz; which is either crystallized in six-sided prisms, terminated by six-sided pyramids, or compact and massive. Many kinds of sandstone are also nearly pure silicic acid, or silica, as it is often called. With very small quantities of oxide of iron and other metals, it forms agate, calcedony, jasper, carnelian, bloodstone, and many other ornamental stones. In amethyst there is only a trace of manganese. In opal there is hardly any impurity; and flint is also very nearly pure silicic acid. The deposits and rocks known by the names of mountain meal, polishing slate, kieselguhr, &c., are also pure silicic acid, in the form of the exuviæ or shells of the diatomaceæ, microscopic organisms which abound in almost all natural waters.

Felspar, which is an ingredient of almost all rocks, is a compound of silicic acid, alumina, and potash; and there are few other minerals occurring in rocks which are not also

silicates. This is the case with mica, hornblende, talc, serpentine, hypersthene, &c.; while porphyry, slate rock, grauwacke, and many others, such as basalt, trap rocks, and lavas, are chiefly modifications of felspar. The simple minerals found crystallized in nodules and veins in all rocks, such as zeolites and the like, are also in most cases silicates.

Silicic acid exists dissolved in sea-water and in all natural waters, although in small proportion, as is proved by the existence and rapid development of the siliceous shelled diatomaceæ in all such waters. Flint has probably been originally in the form of these minute organisms, for it often contains them unaltered. Some springs, especially thermal springs, contain much dissolved silica, as, for example, the Geysers of Iceland.

Pure silicic acid is easily obtained by simply pulverizing rock crystal or white quartz. From impure quartz, or siliceous sand or minerals, it is obtained by fusion with three parts of potash, when a glass is formed, soluble in water. The addition of acids to the strong solution causes the silica to separate as a bulky jelly; if added to the very diluted solution, the silica remains dissolved; but on evaporation to a certain point gelatinizes. The jelly is dried up to a powder, and then the silica becomes absolutely insoluble in water and acids, except hydrofluoric acid. All soluble matter being washed away with the aid of acid, the silica remains as a powder, gray and translucent while moist, snow-white and opaque when dry. However finely divided, it is always gritty to the teeth. Although thus expelled from its salts at ordinary temperatures by almost all acids, at a red heat it expels in its turn all that are volatile at that temperature. With the alkalies it forms glass, soluble when the alkali is in excess, insoluble or ordinary glass when the silicic acid predominates.

The uses of silica are numerous. It is an essential constituent of plants, more especially of the gramineæ, cerealia, and rush, cane, or bamboo tribes. It is employed in the manufacture of glass, and in the form of sand, for building mortar. It is also used along with lime, with which it forms a fusible silicate, as a flux in smelting metals, especially iron. Many forms of it are valued as ornamental stones, of which the opal is the most precious, from its rarity and beauty.

With chlorine, silicon forms a volatile fuming liquid, terchloride of silicon, $Si\,Cl_3$, which decomposes water in the same way as terchloride of boron, $Si\,Cl_3 + 3\,HO = 3\,H\,Cl + Si\,O_3$.

With fluorine it forms a gaseous terfluoride, $Si\,F_3$. This acts on water like the terfluoride of boron, producing a hydrofluosilicic acid. $3\,Si\,F_3 + 3\,HO = (3\,HF, 2\,Si\,F_3) + Si\,O_3$. The hydrofluosilicic acid ($3\,HF, 2\,Si\,F_3$) forms with potash and soda insoluble double salts, as, for example, in this reaction: $3\,HF, 2\,Si\,F_3 + 3\,KO = 3\,KF, 2\,Si\,F_3 + 3\,HO$. The new salt, $3\,KF, 2\,Si\,F_3$, may be regarded as a compound of fluoride of potassium with terfluoride of silicon.

It is in consequence of the great tendency of silicic acid to form the terfluoride with hydrofluoric acid, that the latter acid corrodes glass and porcelain. But the terfluoride of silicon may be prepared in glass vessels, by heating a mixture of fluor-spar, fine sand, and sulphuric acid. The sand is dissolved and the glass escapes. The terfluoride being made to pass through water decomposes it as above explained, forming hydrofluosilicic acid and silicic acid. The latter separates as a jelly, which would soon block up the tube, if we did not protect it by causing the end of it to dip just under the surface of mercury, by which means no water reaches the tube. The liquid is strained off from the jelly, and used as a test for potash and baryta. The jelly when dry forms a fine light bulky powder of silicic acid. If the liquid and the jelly be evaporated together, the terfluoride is reproduced, and the whole disappears.

METALS.

This numerous class of elements is characterized by two properties, both of which are present in every metal. These are, the metallic lustre, and the power of conducting heat and electricity. Metals exhibit also, in general, a strong attraction for the more negative non-metallic elements, being themselves, as a class, positive. It is particularly towards oxygen, chlorine, bromine, iodine, fluorine, sulphur, and selenium, that metals show this attraction; which, however, varies remarkably in degree, from potassium and its congeners, which can with difficulty be kept in the uncombined metallic state, on the one hand, to the noble metals on the other, which frequently cannot be made directly to combine with oxygen.

Before briefly describing the more important metals, for the majority of them need only be enumerated, we shall prefix some general remarks on the physical and chemical properties of the metals, which may thus be conveniently compressed into a very small space. The most important physical properties of metals are their density, fusibility, volatility, malleability, ductility, tenacity, hardness, and colour.

Metals vary much in density; while potassium and sodium are lighter than water, and lithium and calcium not much heavier, many common metals are very heavy; as iron 7 times, silver 10, lead 11, mercury 13, gold 19, platinum 21, and iridium as much as 26 times heavier than water.

Their fusibility is equally various, for mercury melts at 71° below the freezing point of water, potassium somewhere about + 100°, tin at 440°, lead below a red heat, copper and silver at a full red heat, gold and iron at a white heat, platinum requires a heat stronger than that of any furnace, and iridium has not yet been melted.

So also with regard to volatility, mercury boils at about 600°, potassium and sodium at a red heat, arsenic and tellurium even lower, zinc and cadmium at a strong red heat, antimony perhaps at a white heat, while the remaining metals have not yet been seen in the form of vapour or gas.

Of all metals, gold is the most malleable, and may be beaten into leaves of astonishing thinness; platinum and silver come next, then palladium, copper, nickel, tin, lead, cadmium, zinc, and iron. Most of the others are brittle, or have not been tried, from the difficulty of obtaining them.

Ductility is not proportional to malleability. The most ductile metal is platinum, which yields wire so fine as to be almost invisible to the naked eye; then come gold, silver, iron, copper, tin, zinc, cadmium, and lead. The difference between malleability and ductility is strongly seen in iron, which yields very fine wire, but cannot be beaten into thin leaves.

The tenacity of metals is measured by the weight required to break a rod of equal thickness and length of different metals. Iron is the most tenacious, a fine iron wire requiring a comparatively heavy weight to break it. The other ductile metals are all more or less tenacious.

Of the common metals, gold, platinum, and lead are the softest; tin, zinc, cadmium, and silver somewhat harder; copper and iron the hardest. But the hardest of all metals is iridium, which is so very hard that it cannot be wrought by any tools.

The colour of metals is usually either white, with a tinge of some other colour in many cases, or gray. One metal, gold, is yellow, and one, copper, is red. Titanium was supposed to be of the colour of copper, but the cubic crystals formerly supposed to be titanium are now known to contain other elements, cyanogen and nitrogen, in addition to the metal. Silver is pure white; tin and sodium are yellowish-white; zinc and potassium bluish-white; bismuth reddish-white; antimony, arsenic, and iron, gray. Metals often have a different colour in the compact state and in that of powder. Gold in powder is either brown or nearly black, according to the fineness of the powder. Platinum, gray in the compact and even in the spongy state, is jet black in powder.

The chemical characters of metals are determined by their attractions for oxygen, chlorine and its congeners, and

Chemistry. sulphur. A few general remarks on the relations of these substances to metals will greatly facilitate the subsequent description of the individual metals.

The attraction of metals for oxygen, as has been already stated, varies exceedingly. Some, such as potassium and sodium, rapidly attract oxygen from the air, and are thus oxidized. Others, such as iron and copper, attract oxygen very slowly at ordinary temperatures, and only when moist, but are readily oxidized at a red heat, as is seen on the anvil of the blacksmith, where the scales which form on red-hot iron are an oxide of that metal. Others again, as silver, gold, and platinum, not only do not attract oxygen, even at a red heat, but if already combined with it, lose it when heated to redness. Mercury at a certain temperature is oxidized, but the oxide is decomposed at a temperature very little higher.

Some metals decompose water, seizing its oxygen and liberating its hydrogen, at ordinary temperatures, as potassium and sodium. Others only do so at a red heat, as iron and zinc.

There are various methods of oxidizing metals indirectly. Nitric acid oxidizes and dissolves many metals, indeed most of them. It is particularly used for oxidizing copper, mercury, silver, and antimony. Many metals, such as zinc and iron, are oxidized by dissolving them in hydrochloric or sulphuric acid, and then adding an alkali. On the common view, metals when dissolved in sulphuric acid, are first oxidized at the expense of water, and the alkali only separates the ready formed oxide by taking the acid from it. But this cannot apply to the solution of metals in hydrochloric acid, which forms chlorides; and yet alkalies added to chlorides precipitate oxides, just as with the sulphates. This is an additional argument in favour of the opinion that sulphuric acid is a compound of hydrogen, and that in its salts this hydrogen is replaced by metals.

The action of an alkali, potash, on the chloride of a metal, zinc, is as follows, $KO + Zn\,Cl = K\,Cl + Zn\,O$, and its action on sulphate of zinc on the modern view, takes the same form. $KO + Zn\,SO_4 = K, SO_4 + Zn\,O$. We have already explained the action of metals on hydrochloric and sulphuric acids, and shown that the same view may be taken of both, the phenomena being precisely the same, namely, that the metal is dissolved and hydrogen liberated.

A few metals which cannot be dissolved either by hydrochloric, sulphuric, or nitric acids, are dissolved and converted into chlorides by a mixture of nitric and hydrochloric acids, which is called nitro-hydrochloric acid, or aqua regia. It yields abundance of chlorine, which being in the nascent state combines with the metal. The action of the two acids is as follows; $H\,Cl + NO_5, HO = NO_4 + Cl + 2\,HO$. According to some, the nitrous acid and chlorine combine to form a new acid, chloronitric acid, $NO_4\,Cl$, and this is the true solvent. At all events, the result is a chloride of the metal, from which, by means of an alkali, the oxide may be formed.

Metals, having so strong an attraction for oxygen, are usually found combined with it, and the oxides of metals are the most important of their compounds. Protoxides, or oxides of the formula MO, are bases, generally powerful ones; sexquioxides $M_2\,O_3$ are weaker bases; deutoxides MO_2 are neutral, or even weak acids; teroxides, MO_3 are generally strong acids; as are also oxides of the formulæ MO_5 and MO_7. The character, therefore, of the oxide depends on the amount of oxygen in it.

The deoxidation of metallic oxides, or their reduction to the metallic state is an operation of great practical importance, most metals being obtained by this means from their ores. The methods of reduction are various.

Some oxides are reduced by heat alone, as those of silver, gold, platinum, mercury.

Most oxides may be reduced by the combined action of heat and hydrogen, or heat and carbon; the oxygen being carried off as water in the first case, and as carbonic acid gas in the second. Hydrogen is much employed in analytical reductions on the small scale, but carbon is alone used in smelting. The reduced metal is melted by the heat, and falls to the bottom of the crucible or furnace. To prevent it from being again oxidized, a flux is employed, that is, a fusible earthy or saline mixture, which covers the surface of the metal with a fluid mass, and protects it from the air. Chemistry.

Many oxides may be reduced from their solutions by means of other metals having a stronger attraction for oxygen. Thus, salts of silver are reduced by mercury, those of mercury by copper, lead, or tin; copper is reduced by zinc or iron, lead by zinc, tin by zinc. This method is often used in the laboratory. Silver, lead, and tin crystallize beautifully when thus reduced.

Many metallic oxides are also reduced by various deoxidizing agents, both from their solutions, and in the dry way with the aid of heat. Protosulphate of iron reduces gold from its solutions, as do oxalic and formic acids. Silver is reduced by formic acid, by aldehyde, and by oil of cloves. Cyanide of potassium, which combines the deoxidizing agency of carbon with that of potassium, is a most powerful reducing agent at a red heat.

Lastly, several metals are reduced, and that in a compact metallic-looking mass, although from solutions at the ordinary temperature, by the galvanic current. This constitutes the electrotype, which is chiefly applied to copper, silver, and gold. The metals thus obtained are as dense, as hard, and as malleable, as if they had been melted, rolled, and hammered.

Metals are made to combine with chlorine in various ways. Most of them if in a state of fine division combine directly with chlorine gas, generally taking fire in it. But this method is not convenient.

The chlorides of metals may be obtained by acting on the metals or on their oxides with hydrochloric acid, as already explained. As all chlorides, except two, chloride of silver and protochloride of mercury, are soluble in water, this method is much used. The insoluble chlorides are obtained by adding hydrochloric acid or a soluble chloride to any solution of the metal. Thus, hydrochloric acid or chloride of sodium, added to nitrate of silver, precipitate the chloride of silver, $H\,Cl + Ag\,O, NO_5 = HO, NO_5 + Ag\,Cl$, or $Na\,Cl + Ag\,O, NO_5 = Na\,O, NO_5 + Ag\,Cl$.

The volatile chlorides of some metals, such as aluminum, titanium, &c., which decompose water, are obtained by mixing the oxide of the metal with charcoal heated red-hot, and passing chlorine over the mixture. Aided by the attraction of chlorine for the metal, the carbon deoxidizes the oxide, which otherwise it could not do, and the chloride is deposited in the cold part of the apparatus.

When a chloride is to be reduced to the metallic state, hydrogen, aided by heat, may be used on the small scale, but carbon is of no avail.

Chlorides may also be reduced by other metals, and by various mixtures; also by the galvanic current. Chloride of silver is reduced by the action of iron or zinc; by heating to redness with lime, or by boiling with potash and sugar.

All that has been said of the formation and decomposition of chlorides applies also to bromides and iodides, and with the exception that we cannot employ fluorine itself, which is unknown, to fluorides likewise.

With sulphur, most metals combine, when heated along with it. The insoluble sulphurets may also be formed, in solutions of the metal, by the addition of hydrosulphuric acid, or of a soluble sulphuret, which act on the oxides, chlorides, &c., in the same way.

$$MO + HS = HO + MS \text{ and } M\,Cl + K\,S = K\,Cl + M\,S.$$

In some cases the sulphuret of a metal is obtained by

Chemistry.

deoxidizing the sulphate. Thus, in the case of barium or potassium, the sulphurets of which are soluble, the sulphate of the oxide is heated with charcoal or hydrogen.

$$BaO, SO_3 + C_2 = 2\,CO_2 + BaS \text{ and } KO, SO_3 + H_4 = 4\,HO + KS.$$

The sulphurets are reduced in various ways. Some are heated with a mixture of charcoal and carbonate of potash (black flux). The potassium takes the sulphur, while the carbon takes the oxygen of the potash, and the metal is reduced. Some are heated in hydrogen gas, when hydrosulphuric acid is given off, and the metal is left. Some sulphurets are reduced by being heated with other metals, as when sulphuret of mercury is reduced by heating it with iron filings. But on the large scale the usual method is to roast the ore (sulphurets being the chief ores of many metals, as lead, antimony, bismuth, copper, &c.), so as to oxidize both metal and sulphur, and dissipate a great part or the whole of the latter as sulphurous acid. The oxidized residue is then heated with charcoal as usual.

Metals also combine together, especially when heat is applied. It is remarkable that two metals heated together generally melt far more easily than they do separately. This is because the compound metal is always more fusible than the less fusible element, and often more so than the more fusible of the two. Compounds of two or more metals are called alloys, as brass, composed of copper and zinc; bronze, of copper and tin; pewter, of lead and tin; and fusible metal, of lead, tin, and bismuth. Where mercury is one of the elements, the alloy is called an amalgam.

The physical properties of alloys are those of simple metals, and there is nothing in their appearance to indicate their compound nature. In many cases, the addition of a very small proportion of one metal very greatly modifies certain properties of the other, such as fusibility, hardness, tenacity, and the like. A mere trace of arsenic renders gold brittle, and one part of zinc, tin, antimony, and other metals, added to 100, 200, or even 500 parts of iron, much increases both its fusibility and hardness. The subject of alloys is as yet only imperfectly investigated, and many valuable alloys remain to be discovered. It has been ascertained, however, that, while many metals may be fused together in any proportions, the properties for which alloys are valued are best developed when the metals are in atomic proportions, or multiples and submultiples of these.

In briefly noticing the more important metals, we shall divide them into groups, according to their natural analogies. It will be found that these groups are characterized by marked differences in the attraction for oxygen, and also in the nature of the oxides formed, while, in these and many other points, the metals of each group closely resemble each other.

GROUP I.

Metals of the Alkalies Proper.

This group consists of three metals, potassium, sodium, and lithium, which resemble each other as closely as do chlorine, bromine, and iodine. This resemblance is indeed so close that it is often difficult to distinguish between their compounds. They have all so strong an attraction for oxygen that they cannot be preserved in the metallic state unless they are protected from the contact of air, water, and other oxidized substances. They are all oxidized by exposure to air, and all decompose water at ordinary temperatures. Their protoxides are the alkalies, potash, soda, and lithia.

14. *Potassium.*

Symbol K (Kalium). Equivalent = 39 2.

This metal occurs, in the form of salts of its oxide, potash, and in that of its chloride, in the ashes of plants, especially land-plants. Chloride of potassium also occurs in those of sea-plants. Potash also occurs, combined with alumina and silicic acid, in felspar, which, as already mentioned, is one

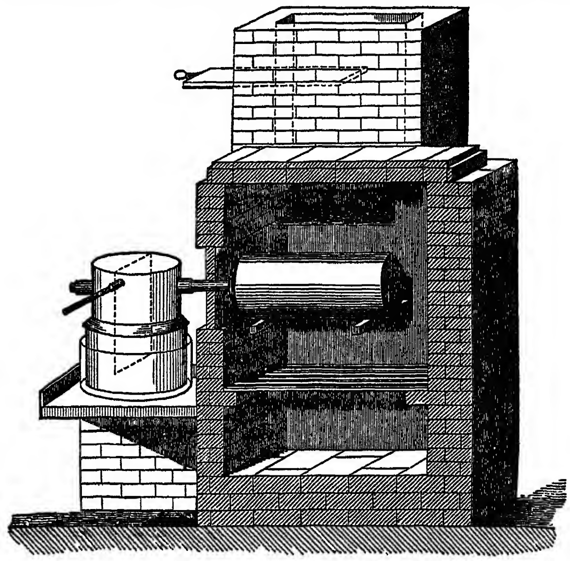

Fig. 29.

of the most abundant minerals. The metal is best obtained from the carbonate of potash, KO, CO_2, by exposing it to a white heat, mixed with charcoal, in a bottle of malleable iron. The carbon is oxidized at the expense of the potash, forming carbonic oxide gas which escapes, while the metal is volatilized and condensed in a receiver filled with naphtha, a liquid containing no oxygen. The process is not very productive, because the carbonic oxide forms, with part of the metal, a dark gray pulverulent compound, which is carried forward by the current of gas, and is apt to choke up the tube. This compound is dangerous, as it takes fire and explodes in contact with water. The metal is purified by melting it under naphtha, and pressing it through leather. If necessary it may be distilled in a small iron retort, and collected in naphtha.

Potassium has a highly metallic lustre, and a bluish-white colour. It is somewhat lighter than water, its density being 8650. It melts at 150°, and if heated takes fire, burning to oxide or potash, KO. It combines with equal energy with chlorine, bromine, iodine, sulphur, &c. Its attraction for oxygen is such that it decomposes all oxidized substances when heated with them, and many at the ordinary temperature. When thrown on the surface of water, it instantly melts, takes fire, and floats on the water, burning with a pink flame. Here the first effect is to deprive the water of oxygen, liberating hydrogen, which is set fire to by the heat evolved. The flame therefore is that of hydrogen and potassium mixed. But if the metal, inclosed in paper, or held by a pair of forceps, be plunged under the surface, no flame appears. Hydrogen gas is abundantly disengaged, and the metal even becomes red-hot under water. The oxide formed is dissolved. Exposed to air, potassium rapidly tarnishes and attracts, first oxygen, then carbonic acid and water, so that, in a short time, it is transformed into a strong solution of carbonate of potash. When heated with the oxides, chlorides, fluorides, &c., of such bodies as boron, silicon, magnesium, aluminum, &c., it deprives these substances of oxygen, and liberates the boron, silicon, and metals they contain.

Protoxide of potassium, or potash, $KO = 47{\cdot}2$. Hydrate of potash or caustic potash, $KO, HO = 56{\cdot}2$.

The anhydrous protoxide or dry potash can only be obtained by heating the metal in dry oxygen gas. When it has once been dissolved, or when obtained from a solution,

it can only be got in the form of the hydrate, which is the true alkali.

Hydrate of potash is obtained by the action of hydrate of lime on a boiling solution of carbonate of potash, when the lime takes the carbonic acid, forming an insoluble carbonate, and the free potash dissolves. The clear solution, boiled rapidly down in a clean iron or silver vessel, till it flows like oil, forms, on cooling, a hard solid mass of hydrate of potash or caustic potash, KO, HO. This 1 eq. of water cannot be expelled by heat.

Caustic potash is very soluble and deliquescent. It also attracts carbonic acid from the air, and is converted into carbonate, if not kept in tightly-stopped vessels. It is very caustic, and has a burning alkaline taste. It seems to act as a caustic from its attraction for water. It neutralizes all acids, forming salts, which are called the salts of potash. Many of them are useful, as the carbonate, nitrate, sulphate, bitartrate, oxalate, &c. The solutions of potash and of its salts, as well as of all other soluble compounds of potassium, are recognised by giving, with excess of tartaric acid, a crystalline precipitate of the bitartrate, with bichloride of platinum a yellow crystalline precipitate of the double chloride of platinum and potassium, and with perchlorate of potash a crystalline precipitate of the perchlorate.

Caustic potash is much used both in surgery and in chemistry. It precipitates the insoluble oxides of most metals. In the arts it is employed in making soap, and in a variety of other ways. The carbonate is used in the manufacture of glass, and the nitrate in that of gunpowder.

Potassium forms, in certain circumstances, not well understood, a peroxide, KO_3, which is a yellow powder of no particular interest.

Chloride of potassium, $K Cl$, is produced when hydrochloric acid acts on potash. $H Cl + KO, HO = K Cl + 2\ HO$. It crystallizes in cubes, has a bitterish saline taste, and much resembles chloride of sodium or sea-salt. This salt is found in kelp, the ashes of sea-weed, and is used in making alum.

Iodide of potassium, KI, is formed along with iodate of potash, KO, IO_5, when iodine is dissolved in solution of potash. $I_6 + 6\ KO = 5\ KI + KO, IO_5$. The mixture, when heated to redness, gives off the oxygen of the iodate, and leaves the pure iodide. $5\ KI + KO, HO = 6\ KI + O_6$. This salt is much used in medicine and also as a reagent in chemistry. It crystallizes in cubes like the chloride, and is soluble in alcohol.

The bromide and fluoride are very like the chloride and iodide, crystallizing also in cubes.

The sulphuret of potassium, KS, is formed by heating the elements together, or by heating sulphate of potash in a current of hydrogen gas. $KO, SO_3 + H_4 = 4\ HO + KS$. It is a white or yellowish powder, soluble in water. There are other sulphurets with more sulphur, especially the pentasulphuret, KS_5, which forms a solution of a deep yellow colour.

15. *Sodium.*

Symbol Na (Natrium). Equivalent = 23.

This metal is found, oxidized, as carbonate, in the ashes of sea-plants, or kelp, barilla, and varec. But it occurs chiefly as chloride of sodium constituting sea-salt and rock-salt, which are most abundant mineral compounds. Chloride of sodium is also present in small proportion in all waters, even in rain-water, and in large amount in salt springs, which are very common in many districts. It is probably also present in all soils, and in most rocks, and is a constant ingredient of the ashes of plants.

Sodium is obtained from the carbonate exactly as potassium is; only, as the metal forms no combination with carbonic oxide, the process is more productive. Like potassium, it must be collected and preserved under naphtha. It has a yellowish-white colour and bright lustre, is rather heavier than potassium, its specific gravity being 9700, and also less fusible and less volatile. It decomposes water, but does not burn on its surface, although if a few drops of water be sprinkled on a bit of sodium, the hydrogen will then take fire and set fire also to the metal, giving an intensely yellow flame. In all other respects sodium resembles potassium; but this character of giving a strong and pure yellow colour to flame is found in all the salts of sodium, and at once distinguishes them from those of potassium, which colour flame of a faint lilac, not easily observed, since the presence of a trace of sodium or of many other metals overpowers it. Potassium itself burns with a lively pink flame, but in its salts the effect is much less marked, whereas in those of sodium the effect on flame is as strong as in the metal itself.

Protoxide of sodium or soda, like potash, is best known in the form of the hydrate, or caustic soda, $Na O, HO$, which is entirely similar to caustic potash, and is prepared from the carbonate exactly in the same way. Hydrate of soda, like that of potash, is deliquescent, and also attracts carbonic acid from the air, but the carbonate of soda differs from that of potash, which is anhydrous and very deliquescent, and can hardly be made to crystallize, whereas carbonate of soda forms very large crystals, containing at least half their weight of water of crystallization and efflorescing, that is, losing water and becoming opaque and powdery in the air.

Soda is best distinguished from potash by its action on flame, and by the characters of its salts. We have seen that potash forms nearly insoluble salts with perchloric acid, bichloride of platinum, and excess of tartaric acid, to which may be added carbazotic or nitropicric acid. With all of these, and indeed with acids in general, soda forms soluble salts. There are only two salts of soda insoluble, or nearly so, namely, the silicofluoride of sodium, formed by hydrofluosilicic acid, when added to soda or its salts, and the antimoniate of soda. But potash also forms an insoluble silicofluoride; and hence the only test which can be used to distinguish soda from potash by forming a precipitate is antimoniate of potash, which of course does not act on the salts of potash. Unfortunately the solution of this test does not keep well; so that chemists generally make use of the action of sodium and its salts on the flame of alcohol, or convert the soda into certain salts which differ from the corresponding salts of potash, as has been mentioned in regard to the carbonate. The sulphate of soda is also efflorescent, and crystallizes in four-sided prisms, while that of potash is anhydrous, and forms six-sided prisms and pyramids. The nitrate of soda forms rhombic crystals, while that of potash yields six-sided prisms.

Soda is used for much the same purposes as potash; and as pure carbonate of soda is now made at a cheap rate from sea-salt, while the commercial carbonate of potash is not only dearer, but very impure, soda is generally preferred. Its chief uses are in making soap (the soaps of soda being hard, while those of potash are soft), and glass. It is also used in bleaching and calico-printing, the cloth being boiled with soda in various processes.

There is a peroxide of sodium, which seems to be a deutoxide, $Na O_2$, but is little known.

Chloride of sodium, $Na Cl$, sea-salt or rock-salt, is the most important compound of sodium. It is the type of all neutral salts, which indeed, as a class, are named from it. It has a purely saline taste, and strong antiseptic properties, fitting it for use as a condiment to food (for which purpose it is indispensable, since blood cannot be formed without salts of sodium), and for preserving meat. Chloride of potassium cannot be used for either of these purposes.

Sea-salt crystallizes in cubes, which are generally hollow.

 Rock-salt is often found in large transparent masses, which cleave readily in the boundary planes of the cube, and may thus be shaped into perfect cubic crystals. It is almost equally soluble in hot and in cold water.

In the arts, salt is used for the production of chlorine, chloride of lime or bleaching powder, and hydrochloric acid. It is also used as a manure.

The bromide, iodide, fluoride, and sulphuret of sodium, are quite analogous to those of potassium.

16. *Lithium.*

Symbol L. Equivalent = 6·5.

This metal, the third of the alkaline group, is rare, occurring only in small proportion, seldom more than 3 or 4 per cent. in a few rare minerals, such as spodumene, petalite, lithion-mica, and lepidolite. The metal is little known, but is analogous to sodium and potassium, being heavier than either, and having apparently stronger affinities.

The hydrated oxide of lithium, L O, H O, analogous to caustic potash and soda, is less soluble and less caustic, but like them attracts moisture and carbonic acid from the air. The carbonate is sparingly soluble. The sulphate, nitrate, and chloride are similar to those of potassium, except that the two last-named salts are deliquescent. Lithium and all its salts are easily recognised before the blow-pipe by the property of giving to flame a blood-red colour. It differs from potassium and sodium also in forming a sparingly soluble carbonate, and a nearly insoluble phosphate.

Lithia has not been applied to any useful purpose, being too rare. It occurs in small proportion in various waters, and possibly contributes to their action on the system. It is worth while to mention that the minerals which contain lithia, especially lithion-mica, and lepidolite, which is a kind of mica, have been found hitherto always associated with certain minerals, namely, topaz, albite, or soda-felspar, and tin ore. The occurrence, therefore, of lithia, especially along with topaz and albite, may be regarded as an indication that tin ore is not distant. The above-named minerals are found together in all the tin districts of Europe, in Cornwall, Saxony, and Sweden, and we have seen the same combination in two districts, one in Scotland, the other in Ireland; in both of which tin ore was also found, but as yet not in available quantity.

The group just described is very remarkable from the great analogy which pervades it, and from its complete parallelism with the group of chlorine, bromine, and iodine. In both, the gradation of properties is perfect, and the atomic weight of the middle elements, sodium and bromine, is, in both cases, the mean between those of the extremes. The most probable explanation of these relations is, that all these bodies are really compound, and contain in each group some common element, the variation in the amount of which causes the change of properties. In other words, these would be regarded as groups of homologous compounds, and they closely resemble such groups. But in the meantime, as we cannot prove them to be compounds, they remain elements to us.

GROUP II.

Metals of the Alkaline Earths.

The next group contains four metals, those of the alkaline earths, in which the gradation of properties seen in the first group is repeated or rather continued. In this group the protoxides are more and more sparingly soluble till the last, which is insoluble; the carbonates are insoluble in water, and the sulphates, with one exception, are either sparingly soluble or insoluble. By these characters they are readily distinguished from the metals of the first group.

17. *Barium.*

Symbol Ba. Equivalent = 68·5.

This metal, which is little known, has been obtained hitherto only by means of a powerful galvanic battery. It is much heavier than the preceding metals, its density being above that of oil of vitriol.

The protoxide of barium or baryta is found in nature, combined with carbonic acid and sulphuric acid, forming the minerals witherite and heavy spar. It occurs also in a few other minerals, chiefly silicates. To obtain the pure anhydrous oxide, Ba O, the carbonate is heated to whiteness, mixed with a little charcoal. By this means the carbonic acid is partly expelled as such, partly as carbonic oxide, and baryta is left. Or the nitrate of baryta is cautiously heated in an earthen crucible, when it melts, and gives off nitrous acid and oxygen, baryta being left. It forms a gray porous earthy mass, which, like quicklime, produces intense heat when brought in contact with water, with which it forms a fine white powder, hydrate of baryta, Ba O, HO. This is dissolved in considerable quantity by hot water, and the hot saturated solution deposits, on cooling, fine tabular crystals of another hydrate, Ba O, 10 HO. The hydrate is much less soluble in cold water than in hot, but still the solution has a strong styptic, almost caustic, alkaline taste, and attracts carbonic acid from the atmosphere, forming the insoluble carbonate. The nitrate of baryta, chloride of barium, and other salts of this base, are easily obtained from the carbonate by the action of the proper acids. But as the carbonate is much more rare than the sulphate, and as the sulphate is quite insoluble in water and acids, it must be decomposed, so as to allow of its being converted into other salts. This is effected by mixing it in fine powder with $\frac{1}{4}$th of its weight of charcoal, and heating the mixture to a strong red heat for two hours in a covered crucible, leaving a small aperture for the escape of gas. The action is as follows: $BaO, SO_3 + C_4 = 4\ CO + BaS$. The products are carbonic oxide gas and sulphuret of barium. The latter compound is dissolved by boiling water, which leaves any impurities as well as any excess of charcoal undissolved. The solution, treated with nitric acid, yields the nitrate; with hydrochloric acid, the chloride; with carbonate of potash, soda, or ammonia, the carbonate; and if boiled with oxide of copper, it yields the hydrate of baryta. The formation of the nitrate is as follows: $BaS + HO, NO_5 = HS + BaO, NO_5$. That of the chloride is $BaS + HCl = HS + BaCl$. That of the carbonate is $BaS + KO, CO_2 = KS + BaO, CO_2$, and that of the oxide is $BaS + CuO = CuS + BaO$. The oxide thus formed instantly combines with water to form the crystallized hydrate.

Baryta is characterized by the extreme insolubility of its sulphate in water and acids, and its salts are used as tests for sulphuric acid; which again is used as a test for baryta. Hydrofluosilicic acid produces, in the salts of baryta, an insoluble crystalline precipitate. Baryta differs also from the three preceding metals in forming an insoluble carbonate, and in its own sparing solubility.

Chloride of barium, prepared as above stated, crystallizes in tabular crystals, Ba Cl, 2 HO. It is much used as a test for sulphuric acid, and as a means of determining the quantity of that acid in analysis. It is also used in medicine.

The sulphuret of barium, Ba S, is soluble in water, as has just been mentioned. It is much used as a means of obtaining the other salts of baryta from the insoluble sulphate.

Baryta, and all its salts, except the sulphate, which, being insoluble in all menstrua, is inert, are very poisonous.

18. *Strontium.*

Symbol Sr. Equivalent = 43·8.

This metal is hardly known, but is very analogous to barium. The protoxide, strontia, is found as carbonate or

strontianite, and sulphate or celestine. The anhydrous oxide, $Sr O$; the hydrates, $Sr O, HO$, and $Sr O, 10 HO$; the carbonates, $Sr O, CO_2$; the nitrate, $Sr O, NO_5$; the chloride, $Sr Cl$; the sulphate, $Sr O, SO_3$, and the sulphuret, $Sr S$, are all prepared precisely as in the case of barium, and are as similar to the corresponding compounds of that metal as the salts of sodium are to those of potassium. The chief differences are, that the sulphate is not absolutely insoluble, and the hydrate rather less soluble than the corresponding compounds of baryta. The chloride is deliquescent, and strontia and all its salts give to flame a fine crimson colour. The nitrate is used, indeed, in making red fire for signals and for the theatres. There is no other useful application of strontia or its salts.

19. *Calcium.*

Symbol Ca. Equivalent = 20.

This metal also is little known. But the protoxide, $Ca O$, is the important substance quicklime. It is found, like baryta and strontia, as carbonate in marble, limestone, chalk, and calcareous spar, and as sulphate in gypsum, alabaster, and selenite. The shells of shell-fish consist chiefly of carbonate of lime, and the rocks above mentioned have been in many cases derived from the accumulation of shells and of their debris, as is proved by the frequent occurrence of chalk, limestone, and marble, entirely composed of shells.

Pure lime, $Ca O$, is obtained by heating pure marble, &c., to redness in a current of air, when the carbonic acid is expelled and quicklime is left. Quicklime is still more sparingly soluble than strontia. It combines with water with great energy, giving out much heat, and producing hydrate of lime or slaked lime, $Ca O, HO$. Hydrate of lime is very sparingly dissolved by water, forming a solution called lime-water, which has an alkaline styptic taste, neutralizes acids, and attracts carbonic acid from the air, forming the insoluble carbonate. Lime-water is a much weaker solution than strontia-water, and strontia-water than baryta-water, so that there is a regular gradation of solubility in the group.

Lime is much employed for making mortar and in agriculture. The uses of marble and limestone for building, and of chalk for various purposes in medicine, and for the preparation of effervescing drinks, are well known. The presence of lime in any solution is detected by adding first ammonia to neutralize any acid, and then oxalate of ammonia, which produces a precipitate of the insoluble oxalate of lime. Lime and its salts are also used to detect oxalic acid.

Chloride of calcium, $Ca Cl$, is formed when hydrochloric acid acts on carbonate of lime. It is very soluble, crystallizes with difficulty, and is very deliquescent. It is much used by chemists from its strong attraction for water, to deprive other substances, such as gases, ethers, and the like, of moisture; also to collect water in analysis, so that its weight may be ascertained.

20. *Magnesium.*

Symbol Mg. Equivalent = 12·2.

This metal is obtained by the action of potassium on the chloride, $Mg Cl + K = K Cl + Mg$. It is silvery white, of a brilliant lustre, and malleable. It may be kept in dry air or under water. When heated in oxygen it burns with much light, producing the protoxide or magnesia, $Mg O$.

This oxide magnesia, $Mg O$, is best obtained, like lime, by heating the carbonate. Hence it was called calcined magnesia, the carbonate being then called magnesia. Magnesia is insoluble in water, but has an earthy taste. It is quite white, while the three preceding alkaline earths are more or less gray. Hydrate of magnesia, $Mg O, HO$, is formed by precipitating the soluble salts of magnesia by caustic potash, soda, or ammonia. It is white, and resembles the anhydrous oxide, into which it is converted by a low red heat, water being expelled.

Magnesia is a strong base, and neutralizes all acids. It is distinguished from the three preceding oxides by its insolubility and by forming a soluble sulphate. It agrees with them in forming an insoluble carbonate. It is found in nature as carbonate in some localities, but chiefly in the form of the double carbonate of lime and magnesia, dolomite, or magnesian limestone. The sulphate occurs in some springs, as in Epsom and Cheltenham waters. Hence its name of Epsom salt.

Magnesia and its carbonate are much used in medicine as antacids. The sulphate is an excellent laxative.

Magnesia has a remarkable tendency to form double salts, as carbonate of lime and magnesia; sulphate of magnesia and potash (ammonia and soda may be substituted for the potash); and phosphate of ammonia and magnesia. The latter being quite insoluble, especially where an excess of ammonia is present, magnesia is detected by converting it into this double phosphate, which is done by adding first carbonate of ammonia and then phosphate of soda.

The chloride of magnesium, $Mg Cl$, is obtained by dissolving magnesia in hydrochloric acid, evaporating to dryness, and igniting after the addition of sal-ammoniac, the vapours of which protect the chloride from the action of the air, which would otherwise oxidize the metal, expelling the chlorine. The fused mass of chloride must be kept in well-stopped vessels, as it is very deliquescent. It is from this salt that magnesium is obtained, and we mention it here because, as the metal is not rapidly oxidized in the air like those which precede, and appears to be malleable, it is possible that it may be in time applied to useful purposes.

It will be observed, that while barium, strontium, and calcium form a triad, parallel to that of potassium, sodium, and lithium, and with the same gradation in properties, such as solubility, force of attraction, and atomic weight, magnesium, with some points of analogy to these, yet in other points stands by itself. It is the first metal which, although having a strong attraction for oxygen, can yet be kept unchanged in air and water, the first also whose oxide (a protoxide) is insoluble in water. But it is placed with the three preceding metals, because it differs still more from those which follow. Strictly speaking, it does not belong to the same group with the three which precede it, and which form so well-marked a triad; and we shall see that its analogies are rather with zinc, a metal belonging to a different part of the series. It is, in fact, isomorphous with zinc.

GROUP. III.

Metals of the Earths Proper.

The next group is that of the metals of the earths proper, which are five in number. Only one of these, however, is of much importance, the others being rare, and two of them exceedingly so. They form sesquioxides, which are bases, but not powerful, being expelled from their combinations by protoxides in general. These oxides are insoluble in water, and have an earthy aspect. The metals are little known, but aluminum is said to have been recently obtained on a larger scale than formerly, and to admit of useful applications.

21. *Aluminum.*

Symbol Al. Equivalent = 13·7.

This metal is obtained from the chloride by the action of potassium, and has hitherto been described as a dark-gray nearly black powder, infusible, but taking metallic lustre under the burnisher. Recently it is said to have been deposited on the surface of other metals, by means of the galvanic current, as copper is in the electrotype, in a perfectly compact metallic state, with a bright silvery lustre and co-

lour, and permanent in the air. When heated in oxygen, it burns with a brilliant light to sesquioxide. It is this sesquioxide which is so important from its abundance in nature.

Sesquioxide of Aluminum—Alumina, $Al_2O_3 = 51{\cdot}4$.

This earth is, next to silica, the most abundant solid constituent of the earth's crust. It forms a large proportion of all felspar, and felspar is a constituent of most rocks. In decayed or disintegrated felspar, which constitutes clay, alumina preponderates; and in some clays, such as pipe-clay and porcelain clay, it is nearly pure. Alumina also occurs crystallized in the sapphire and ruby, which contain only a mere trace of colouring matter, and in corundum.

Pure alumina is obtained from alum, which is a double sulphate of alumina and potash, by adding carbonate of potash, which produces a bulky gelatinous precipitate of hydrate of alumina. This is well washed with hot water. Since alumina does not combine with carbonic acid, the carbonic acid of the carbonates escapes as gas. The washed hydrate is not yet pure, retaining some potash. It is dissolved in hydrochloric acid, and reprecipitated by ammonia, again washed, dried, and ignited, when the bulky hydrate, becoming anhydrous, shrinks to a small bulk. Another method, which does not require the long and tedious washing of the hydrate, is to precipitate alum by chloride of barium, which throws down the sulphuric acid as sulphate of baryta, while chloride of potassium and hydrochlorate of alumina remain dissolved. The solution is dried up and the residue ignited, when the hydrochloric acid is expelled, and there is left a mixture of anhydrous alumina and chloride of potassium. The chloride is removed by hot water, and the alumina, which in this state is easily washed, is then dried and ignited, when it appears as a dense earthy white powder. That obtained by igniting the hydrate is translucent, and forms hard lumps.

Alumina is insoluble in water, but forms with it a plastic mass, which can be moulded into any shape, and when ignited retains the form given to it, and becomes hard, and much contracted in volume from the loss of water. When freshly precipitated the hydrate is very soluble in acids, but after ignition it dissolves in them very slowly. Its solutions have a sweetish astringent taste, and are styptic. Alumina is recognised by its being precipitated by caustic and carbonated potash, soda, and ammonia; and by its redissolving easily in an excess of caustic potash or soda, but not in ammonia. It may also be recognised by forming, with sulphuric acid and potash, a solution which, on evaporation, readily yields octahedral crystals of alum.

Alumina is useful as the chief constituent of all plastic clays, such as pipe-clay, porcelain-clay, brick-clay, and fire-clay. In these it is combined with a little silica. In the form of alum and acetate of alumina, it is much employed in dyeing and calico-printing. Alum is also used in medicine.

Alumina is the first sesquioxide we have come to, and is the type of such oxides.

Chloride of aluminum is a volatile fuming liquid, formed when chlorine gas is passed through a red-hot tube containing alumina intimately mixed with charcoal. The charcoal, aided by heat alone, cannot deoxidize alumina; but when the attraction of chlorine for the metal is added, the carbon is oxidized, and passes off as carbonic acid or carbonic oxide. $Al_2O_3 + C_3 + Cl_3 = 3\,CO + Al_2Cl_3$. The chloride is a sesquichloride. It must be carefully kept out of contact with water, which it instantly decomposes, forming hydrochlorate of alumina: $Al_2Cl_3 + 3\,HO = (Al_2O_3,\ 3\,HCl)$. This action on water is the reason why the chloride fumes in the air. Potassium decomposes it, setting free the metal as a dark-gray powder.

The other metals of this group are—22. Glucinium, $G = 26{\cdot}5$, which is found as sesquioxide in the beryl and the emerald, and is named from the sweet taste of its salts. The oxide glucina, G_2O_3, resembles alumina, but it differs from it in being soluble in carbonate of ammonia. 23. Yttrium, $Y = 32{\cdot}2$, the sesquioxide of which, or yttria, is found in two or three very rare minerals, such as gadolinite, and yttrotantalite, which occur at Ytterby, in Sweden; hence the name. Its salts are also sweetish, but it is of little importance. 24. Thorium, $Th = 59{\cdot}6$, found only in one very rare mineral, thorite, and hitherto only seen by one or two chemists; and 25. Zirconium, $Zr = 22{\cdot}4$, the sesquioxide of which, zirconia, is found in the zircon or hyacinth. It also is somewhat analogous to alumina, but is not of sufficient importance to justify us in dwelling on it more fully.

Zirconium, in some of its properties, connects this group with the next.

GROUP IV.

This group consists of metals, the oxides of which are so little known, that we cannot say with certainty that any one of them is known in a perfectly pure state. The oxides of these metals, in fact, occur generally together, and being very similar to one another, their separation is a matter of very great difficulty. We shall therefore only mention their names, for their atomic weights are for the most part still doubtful. They are, 26. Cerium; 27. Lantanium; 28. Didymium; 29. Erbium; and 30. Terbium. It is in this group that the oxides begin to be coloured. Peroxide of cerium is brown, and the salts of several of them have some degree of colour. It is now believed that the colour observed in some of the salts of yttria really depends on the presence of one or more of these metals. Zirconium has also a certain degree of analogy to tin.

GROUP V.

We shall now proceed to a group of metals of far greater importance, the first of which is iron. The metals of this group are seven in number, namely, iron and manganese, zinc and cadmium, cobalt and nickel, and tin. It will be seen that six of them are enumerated in pairs, and in fact the two metals of each pair have not only a striking analogy in many points, but also occur associated, one being seldom found without the other. In this group the attraction for oxygen is still very powerful, but the metals do not decompose water rapidly at ordinary temperatures, although they do so at a red heat. Their protoxides are powerful bases, and their sesquioxides, where they exist, are weak bases. When they form teroxides, these are strong acids. The compounds of most of them are coloured.

31. *Iron.*

Symbol Fe (Ferrum). Equivalent = 28.

This, the most valuable of all metals, is the first we have come to that is found uncombined, or in the metallic state; it occurs in that state in meteoric iron, and perhaps also in masses of terrestrial origin. There are, in different parts of the world, as in Siberia, in South America, and on the west coast of Africa, large masses of iron, declared by the native tradition to have fallen from heaven. That on the coast of Africa is almost a hill in size, the others are smaller. but yet of many tons weight, and many still smaller masses of the same kind exist. There is one of several tons weight in the court of the Government Building at Aix la Chapelle, which was found just below the surface of one of the streets, and of the fall of which no record is left. It probably fell before the city was founded. All the known masses of meteoric iron agree in character, being very hard, but malleable, and containing small quantities of nickel, cobalt, chromium, arsenic, and sulphur, with frequently a little silica. Such masses have been often seen to fall, and have been picked up while yet hot. When they fall at night, they are seen as luminous meteors, which finally explode and burst into fragments, and these, if large, bury themselves in the ground by the force of their fall. This

form of iron, however, is rare, although very interesting, from its peculiar composition, always containing the same impurities, and from the uncertainty of its origin. At one time these meteorites were supposed to come from the moon; but the prevalent opinion now is, that they are portions of planetary matter, either undergoing condensation, or else the fragments of some heavenly body that has burst or exploded, and continuing to revolve round the sun. They frequently enter our atmosphere, when they cross the earth's orbit, and then appear to take fire in it, and to be attracted to the surface. Multitudes of them pass through without falling, their centrifugal force being sufficient to resist the gravitation of the earth.

Iron is usually found oxidized; either as sesquioxide $Fe_2 O_3$, called red hematite, or black hematite, a hydrate of the same oxide; or carbonate of protoxide, FeO, CO_2 which is called clay iron ore; or magnetic oxide, or black oxide of iron, or loadstone, of which there are two kinds, $Fe_3 O_4$ and $Fe_4 O_5$. It also occurs as bisulphuret of iron, $Fe S_2$, called iron pyrites, and another sulphuret, called magnetic pyrites. The metal is obtained chiefly from hematite, magnetic oxide, and carbonate. These ores are heated with charcoal or coke, and a flux composed of sand and limestone. The reduced metal combines with a small quantity of carbon, forming a fusible compound, pig or cast-iron. This is subsequently melted in a puddling furnace, and exposed to a current of air, to burn off the carbon. As it becomes purer, it becomes also less fusible, till at last at a white heat the purified metal is only in a pasty, not a fluid state. At this stage it is hammered and rolled to expel the last traces of carbon, and then constitutes pure or malleable iron, such as is used for horse-shoes, horse-shoe nails, gun-barrels, and rails, as well as wire; for it is only when pure that it can be drawn out into fine wire.

Iron has a specific gravity of about 7800 (water = 1000). It is rather soft, especially when hot, and malleable. It is fusible only in the most intense heat of a wind furnace. Heated in a current of air, or in oxygen, to whiteness, it burns and is rapidly oxidized. At a red heat it is still oxidized on the surface; and the oxide, which is black or magnetic oxide, scales off under the hammer, and is called smithy ashes. At ordinary temperatures, if exposed to air and moisture, it is slowly oxidized, forming the brown sesquioxide, and is said to rust.

The uses of iron, in the pure metallic state, are too well known to require enumeration. The chief objection to it is that it cannot be cast nor even hammered at ordinary temperatures, so that it must be heated red-hot in order to be manufactured. Its value depends on its tenacity, a property in which it surpasses all other metals.

Iron and Oxygen.

Iron forms several oxides. Three appear to be direct compounds of iron and oxygen, and two to be composed of the others united together.

1. Protoxide of iron, FeO, is obtained by heating the carbonate or sesquioxide to a low red heat in hydrogen gas. If heated too strongly, it is reduced to the metallic state. When pure, it is of a grass-green colour, but it is apt to absorb oxygen from the air and to become sesquioxide, so that it is little known. It is a powerful base, and its salts are either bluish-green or colourless, the latter in a few cases only. These salts have an inky taste, and give a deep blue precipitate of Prussian blue with the ferridcyanide or red prussiate of potassium. Caustic alkalies precipitate a white hydrate, which instantly attracts oxygen, and passes through green to the brown sesquioxide. Carbonated alkalies give a white bulky carbonate, which also becomes green, and finally brown, being converted into sesquioxide, and losing its carbonic acid. Hydrosulphuric acid or sulphuretted hydrogen does not precipitate these salts; sulphuret of ammonium causes a black precipitate of sulphuret of iron. Infusion of galls and meconic and sulphocyanic acids have no action on pure solutions of the protoxide. That oxide and its salts are characterized by their strong tendency to pass into sesquioxide, by absorbing oxygen; and they deoxidize many substances in consequence. The carbonate occurs in many mineral springs, dissolved by excess of carbonic acid.

2. The sesquioxide or peroxide of iron $Fe_2 O_3$, is far more permanent, not having any tendency to absorb oxygen under ordinary circumstances. It is found pure in red hematite, hydrated in black hematite. To prepare it, the sulphate of the protoxide, or green vitriol, is boiled with nitric acid, some sulphuric acid being added, when it becomes sulphate of the peroxide or persulphite. The addition of an alkali throws down a bulky brown hydrate of the sesquioxide, which, being washed, dried, and ignited, leaves the sesquioxide. It is a weak base, and is expelled from its salts by all protoxides, even by protoxide of iron. Its formation from the protosulphate or green vitriol is as follows:— $2\ (FeO, SO_3) + NO_5 + SO_3 = NO_4 + (Fe_2 O_3, 3\ SO_3)$. Like alumina and other sesquioxides, it requires 3 eqs. of acid to form a neutral salt. On account of the permanence of this oxide, when we wish to test for iron, it is first converted into sesquioxide by boiling with nitric acid. Its characters are well marked. Alkalies, caustic and carbonated, throw down a brown precipitate of sesquioxide, which does not combine with carbonic acid. Ferrocyanide of potassium, or yellow prussiate, produces the deep blue precipitate of Prussian blue; the red prussiate only changes the colour of the solution to a dirty green. Infusion of galls produces ink, and sulphocyanic and meconic acids produce a deep blood-red colour. The salts of sesquioxide of iron are generally brown, and have a strong styptic inky taste.

Both oxides and their salts are used in medicine, as tonics and astringents. The salts of the peroxide are much employed in dyeing and calico-printing, as they strike either black or various shades of purple, lilac, and gray, with cochineal, logwood, and other red dyes, with which alumina gives crimson or pink colours.

The blood of animals contains iron in considerable quantity, which is found in the ashes of the blood as sesquioxide. It is present chiefly in the red globules, and indeed in the colouring matter of the globules. But it is not known whether their colour depends on the presence of iron, nor in what form of combination the iron exists. There can be no doubt that it has an important function to perform, probably connected with the absorption of oxygen in respiration; and as iron is thus essential to animal life, so it is found as a never-failing constituent of those plants on which animals feed, and that, in the form of sesquioxide, at least, it takes that form in the ashes.

3. Ferric acid, FeO_3, is formed when the sesquioxide is ignited along with potash, or with nitrate of potash. The oxide takes up oxygen, and the acid thus formed combines with the potash, forming a salt which is very soluble in water, to which it gives a deep purple colour. It does not keep, however; for on standing, oxygen is evolved, and sesquioxide is deposited. It may be preserved somewhat longer, and even obtained in dark crystalline grains, if the solution contain a large excess of potash. Ferrate of potash, KO, FeO_3, is rapidly deoxidized by contact with organic matter, such as the skin, or paper.

4. Magnetic oxide or black oxide of iron, exists in two forms, both of which may be produced artificially by precipitating a mixture of protoxide and sesquioxide in due proportion. The two magnetic oxides are $Fe_3 O_4$ and $Fe_4 O_5$. The former may be regarded as formed of 1 eq. of protoxide and 1 eq. sesquioxide, $FeO + Fe_2 O_3 = Fe_3 O_4$. The latter contains the elements of 2 eqs. protoxide, and 1 eq. sesquioxide, $2\ FeO + Fe_2 O_3 = Fe_4 O_5$. The native loadstone

or natural magnet, or magnetic iron ore, is a mixture or compound of the two. To prepare the oxide $Fe_4 O_5$ artificially, sulphate of the protoxide is divided into two equal parts, and one of these converted into sulphate of sesquioxide by boiling with nitric acid. The two portions are then mixed, and the addition of an alkali, aided by a boiling heat, throws down a black precipitate, which, when dry, is strongly magnetic, and does not attract oxygen from the air. As the two halves of the sulphate contain equal quantities of iron, the oxide thus prepared must be that which is $Fe_4 O_5 = 2\ Fe O + Fe_2\ O_3$. The oxide $Fe_3 O_4$ is prepared exactly in the same way, only two-thirds of the sulphate are converted into sesquioxide, which gives the oxide $Fe_3 O_4 = Fe O + Fe_2 O_3$. This also is black, permanent, and magnetic.

With chlorine, iron forms two chlorides. The protochloride, $Fe Cl$, is formed when iron is dissolved in hydrochloric acid. It is soluble, and has the green colour and character of a salt of protoxide. The sesquichloride, $Fe_2 Cl_3$, is formed when the sesquioxide is dissolved in hydrochloric acid, and evaporated to dryness. It forms an orange yellow mass, which is volatile at a high temperature. It is much used in medicine, in the form of an alcoholic tincture, called tincture of muriate of iron. It occurs among the volatile products of volcanic action.

The protoiodide of iron, $Fe I$, is formed, when iron and iodine, the former in excess, are placed in contact under water. Heat is developed, and a green solution of the iodide is formed. When boiled down, it leaves a dark green deliquescent mass. The iodide is decomposed by the oxygen of the air, which sets free iodine, and converts the iron into sesquioxide. The iodide is much used in medicine, and is preserved by drying it up with the addition of sugar, which covers the particles, and protects them from the air. Sugar is used in the same way to preserve the precipitated carbonate of protoxide of iron from oxidation.

Sulphur and iron unite in several proportions. The protosulphuret, $Fe S$, is formed when iron filings and sulphur are heated together, when much heat and light are developed. It is also formed when a stick of sulphur touches a white-hot rod or bar of iron. The bar is instantly perforated, and the melted sulphuret drops down. It is used in the preparation of hydrosulphuric acid. The bisulphuret $Fe S_2$, called iron pyrites or firestone, because some varieties of it absorb oxygen from the air and become hot, is a very abundant mineral. It forms cubic, octohedral, or dodecahedral crystals, of a yellowish colour and metallic lustre. When heated, it yields half its sulphur as a sublimate, but as the mineral generally contains arsenic, sulphur thus obtained is only used when better cannot be procured. Magnetic pyrites, $Fe_3 S_4$, is characterized by its magnetic properties.

With carbon, iron forms two important compounds, which, however, contain very little carbon. These are cast-iron, which contains from 2 to 4 or 5 per cent., and steel, which contains only 1 or 2 per cent. of carbon. The former is hard, fusible, and brittle, but may be cast into any shape. The latter is sufficiently fusible to be cast if required, hard and elastic, as well as tough, which properties fit it for springs and cutting instruments. Both are made by simply heating iron in contact with charcoal.

No definite compound of iron with phosphorus is known; but a very small amount of phosphorus destroys all the good qualities of iron.

32. *Manganese.*

Symbol Mn. Equivalent = 27·6.

This metal appears to accompany iron; for while the ores of iron almost always contain traces of manganese, the ores of manganese contain traces of iron or even larger quantities. The metal itself is little known, but may be got by heating to intense whiteness oxide of manganese with charcoal. It is fusible with extreme difficulty, and so brittle as to be of no use in the metallic state. In appearance it resembles iron. Its density is 8000.

The only important compounds of manganese are its oxides, especially the deutoxide or peroxide. This occurs in considerable quantity in veins and nodules, in the form of black prismatic crystals, or as a crystalline mass with a black streak. One variety of it, called wad, is earthy in aspect. It also occurs hydrated, when it is more brown, and has a brown streak. The hydrate is less valuable than the pure oxide. Peroxide of manganese is much used in the manufacture of bleaching powder, and also by chemists in preparing oxygen and chlorine. Its formula is $Mn O_2$, and it is a neutral or indifferent oxide.

Protoxide of manganese, $Mn O$, is obtained by heating the carbonate, $Mn O, CO_2$, in a current of hydrogen; it is of a grass-green colour, and unless it be very compact, attracts oxygen from the air, and passes into peroxide. It is a powerful base, and forms salts which are colourless, or have a slight pink tinge. Alkalies produce in them a white precipitate of hydrated protoxide, rapidly passing into the brown hydrated peroxide by absorption of oxygen. Carbonated alkalies cause a white precipitate of carbonate of protoxide, which in drying becomes very slightly coloured, but is not altered in composition. Sulphuret of ammonium causes a flesh-coloured precipitate of hydrated sulphuret, while bleaching solution, and ozonized air, precipitate hydrated peroxide. This action of bleaching liquor is employed in calico-printing, to give a fine bronze brown.

Sesquioxide of manganese, $Mn_2 O_3$ is left when the peroxide is heated to redness in close vessels. It is of a pale brown, and in its relations analogous to sesquioxides of aluminum and iron. It gives to glass an amethyst colour, and is believed to be the cause of the colour of the amethyst.

Red oxide of manganese, $Mn_3 O_4$, is left when any oxide is ignited in open vessels. It seems to be a compound of protoxide and sesquioxide, analogous to magnetic oxide of iron.

Manganic acid, $Mn O_3$, is formed in the same way as ferric acid; and its solution and that of its salts have a fine deep emerald green colour. Manganate of potash, $KO, Mn O_3$, is isomorphous with sulphate of potash. Its fine green solution cannot be preserved, but, like that of the ferrate, loses oxygen, while peroxide is deposited. But if diluted with hot water, the colour changes from pure green to bottle-green, olive-green, bluish-green, bluish-purple, and finally to a splendid reddish-purple, which belongs to the salt of another acid, permanganic acid.

Permanganic acid, $Mn_2 O_7$, is obtained in combination with potash, by adding hot water to the solution of the manganate. When the change is complete, a brown precipitate of hydrated peroxide settles, and the clear red solution, evaporated to a small bulk, yields beautiful bronze-coloured crystals of the permanganate, which have a metallic lustre; from the intensity of their purple colour, one small crystal will give to a quart of water a fine deep purple tint. This salt is much more permanent than the green manganate, but is rapidly deoxidized by all organic substances. In fact, it is a most powerful oxidizing agent, and produces peculiar results, from the nature of its composition, and the presence of an alkali. It is used in organic research. Its formula is $KO, Mn_2 O_7$, and its formation from the green manganate is as follows: $3\ (KO, Mn\ O_3) = Mn\ O_2 + 2\ KO + (KO, Mn_2\ O_7)$, so that the liquid becomes alkaline from free potash, and peroxide is separated. The action of this salt on sugar will serve as an example of its action on organic substances, by which acids are generally formed which combine with the potash. We shall suppose the sugar to be dry grape sugar, $C_{12} H_{12} O_{12}$.

$$C_{12}H_{12}O_{12}+6\,(KO, Mn_2O_7) = 12\,MnO_2+12\,HO+6\,(KO, C_2O_3)$$

One eq. of sugar, with 6 eqs. of the salt, yield 12 eqs. of peroxide, 12 of water, and 6 of oxalate of potash. This proves that no part of the carbon in sugar can be in the form of carbonic acid, as some have supposed. For we get all the carbon as oxalic acid; and as that acid contains less oxygen than carbonic acid, it is impossible that it can have been formed from carbonic acid by means of a powerful oxidizing agency.

There are two chlorides of manganese, the protochloride $Mn\,Cl$, and the perchloride $Mn_2\,Cl_7$, corresponding to permanganic acid. The protochloride, from which all the salts of manganese are obtained, is obtained pure from the solution made in preparing chlorine by the action of hydrochloric acid on the peroxide. This solution contains protochloride of manganese, and sesquichloride of iron. One part of it is precipitated by carbonate of soda, and the washed precipitate, consisting of carbonate of protoxide of manganese with sesquioxide of iron, is added to the remaining solution and boiled. The protoxide in the precipitate expels the iron from the solution, so that, if the proportion of the solution precipitated has been rightly calculated, the whole manganese is now found in the liquid, and all the iron in the precipitate. It is best to manage it so that a little manganese remains in the precipitate, for in that case no iron can remain in the liquid, provided the iron has been in the state of sesquichloride or sesquioxide. This very beautiful process, in which one part of an impure solution is made to purify the whole, itself included, depends on the fact that protoxides, even in the form of insoluble carbonates, expel sesquioxides from their solutions. The solution must first be rendered neutral by evaporation to dryness, for free acid would prevent the result. A solution of protochloride of manganese is thus obtained quite free from iron, and containing only traces of copper, cobalt, and nickel. The first is separated by hydrosulphuric acid; the two others by a few drops of sulphuret of ammonium. From the pure chloride, which forms pink crystals, all the salts of manganese may easily be prepared.

The perchloride is volatile, and its vapour is of a greenish-yellow colour. It has not been much studied, but it is said to decompose the vapour of water, producing a purple cloud of minute particles of permanganic acid, along with hydrochloric acid.

Protosulphuret of manganese, $Mn\,S$, is formed as a flesh-coloured hydrate, when sulphuret of ammonium is added to the salts of protoxide of manganese. This appearance is quite characteristic of the pure salts of manganese.

It is worthy of notice, that while 1 eq. of manganese is isomorphous with 1 eq. of sulphur in the manganate of potash, isomorphous with sulphate of potash, 2 eqs. of manganese are isomorphous with 1 eq. of chlorine in the permanganate, isomorphous with perchlorate. The four salts are as follow:—Sulphate of potash, KO, SO_3. Perchlorate of potash, $KO, Cl\,O_7$. Manganate of potash, $KO, Mn\,O_3$. Permanganate of potash, $KO, Mn_2\,O_7$. This seems to indicate that our equivalent of chlorine ought to be halved, as it is on the Continent, when the formula of the perchlorate would be, KO, Cl_2O_7. Such a change, however, would imply the halving of the equivalents of bromine, iodine, hydrogen, and many metals; and although it may ultimately be adopted, at present it would cause confusion.

Iron and manganese form a group of two, with many points of analogy, and remarkable in this, that their atomic weights are almost if not exactly the same. We have now to examine two similar pairs.

The first of these includes zinc and cadmium. These metals are usually found, like the two last, together, and the analogy between them is very strong. Both are obtained from the chief ore of zinc, calamine, or silicate of oxide of zinc, and both are volatile at a red heat.

33. *Zinc.*

Symbol Zn. Equivalent = 32·6.

The ore is heated with charcoal in crucibles closed above, from which a tube leads downwards, and conveys the vapours to the condensing vessel where they are collected in water. The vapours which first come burn, if set fire to, with a peculiar brown flame, and deposit an impure oxide, containing nearly all the cadmium, which is more volatile than zinc.

When this brown blaze, as it is called, is over, the pure vapour of zinc is collected in water, where it forms metallic masses. Since the discovery of cadmium, the brown blaze is no longer burnt but collected separately in water if the cadmium be required; or the oxide may be used to obtain that metal. The above process is called distillation per descensum.

Zinc is a crystalline, easily-fusible metal, of a bluish-white colour, specific gravity about 7000. It melts at a low red heat, and if heated more strongly is converted into vapour, which takes fire and burns with a greenish-white flame, producing the oxide, a large part of which is carried upwards by the heated current, and deposited in light white flocks, called Lana Philosophorum. The oxide remaining in the crucible, when washed from any particles of metal, is pure, and is not in itself volatile. The metal is not malleable when cold, but is broken, although not very easily, by the hammer. At 300° it may be rolled into plates or sheets, which are used instead of sheet lead.

There is only one oxide of zinc, the protoxide, $Zn\,O$, which is prepared by burning the metal, or precipitated as a hydrate by the alkalies, an excess of which redissolves it. The best way is to precipitate it as carbonate, and to ignite that salt, when the oxide is left. While hot, it is yellow, but becomes white on cooling. It is distinguished from alumina in solutions by its ready solubility in excess of ammonia. Its salts are colourless and generally isomorphous with those of magnesia. The sulphate of zinc is so like that of magnesia, that its density alone distinguishes the two salts, unless we apply chemical tests. Solutions of zinc give, when quite neutral, a white precipitate of hydrated sulphuret with hydrosulphuric acid, but in acid solutions this test does not act. Sulphuret of ammonium produces, in neutral solutions, the same compound more abundantly. Ferrocyanide of potassium causes a white precipitate, and the action of caustic and carbonated alkalies has been already mentioned. The salts of zinc have a styptic metallic taste. The sulphate, acetate, and carbonate, as well as the oxide, are used in medicine. The sulphate is astringent, and in large doses emetic and poisonous. It is much used as a collyrium.

There is only one chloride, the protochloride, $Zn\,Cl$, formed when zinc is dissolved in hydrochloric acid. It forms a crystalline deliquescent mass, which, in solution, is used to preserve anatomical preparations, and to prevent decay in wood, according to Sir W. Burnett's method.

The iodide, $Zn\,I$, is made by the action of an excess of zinc on iodine under water, when the compound dissolves. It is used in medicine.

The sulphuret, $Zn\,S$, or zinc blende, is a common mineral in Cornwall and other mining districts. It forms dense black crystals, and when converted into oxide by roasting, yields the metal when heated with charcoal. The white hydrated sulphuret, formed in solutions of zinc by sulphuret of ammonium, when heated, loses water, and becomes black.

Zinc is much used in the form of sheets and pipes, not having the poisonous properties of lead. It is also a constituent of brass and of German silver. One of its chief uses now is the formation of galvanic batteries, in which plates of zinc are placed alternately with those of copper, or of platinized silver. For the purposes of the electric telegraph and the electrotype zinc is therefore most valuable.

Carbonate of zinc prepared by a peculiar process has lately been introduced under the name zinc white, as a substitute for the poisonous white lead.

34. *Cadmium.*

Symbol Cd. Equivalent = 56.

The preparation of this metal from the common ore of zinc, of which it constitutes from 1 or 2 to 10, 12, or even 15 per cent., has been described under zinc. Cadmium also occurs in very small quantity as sulphuret, or cadmium blende, in fine orange crystals, of an octahedral form, first observed in trap rock in the west of Scotland by Lord Greenock, and hence called, as a mineral, Greenockite. In this rare ore no zinc is present.

Cadmium has a darker gray colour than zinc, and is very fusible and malleable. Its specific gravity is 8700. It is more volatile than zinc, and very combustible at a high temperature. Like zinc it forms but one oxide CdO, chloride $CdCl$, sulphuret CdS, &c. Its salts, like those of zinc, are astringent, styptic, and emetic. Sulphate of cadmium is an excellent collyrium. Cadmium is reduced to the metallic state from its solutions by zinc, and this furnishes a beautiful method for its purification. The oxide of the brown blaze of zinc works contains much zinc and some cadmium. It is dissolved in hydrochloric acid or sulphuric acid, and the acid solution in a platinum vessel acted on by a piece of zinc. The reduced cadmium adheres to the platinum, and after being washed may be dissolved off by hydrochloric acid. Another character of its salts is, that their acid solutions give with hydrosulphuric acid a fine orange yellow precipitate of sulphuret of cadmium. In this point it agrees with arsenious acid; but there is no difficulty in distinguishing between a basic oxide, such as oxide of cadmium, which forms an insoluble carbonate and is itself insoluble in water, and a soluble acid like arsenious or arsenic acid.

Zinc and cadmium form a pair of closely analogous metals, and the atomic weight of cadmium is not far from double that of zinc. It is probable that both metals will be used to coat the surface of other metals as we coat copper with tin; for already lead has been successfully coated with both, and even iron has been coated with zinc, under the name of galvanized iron. The two metals in question have the advantage of not being poisonous, as lead and copper are.

The next pair is even more remarkable for the analogy between them. The metals are cobalt and nickel. Like the metals of the two preceding pairs they are found associated, the ores of the one always containing more or less of the other. They are both as infusible as iron and manganese, and have more analogy to them than to zinc and cadmium. Indeed, there is a curious relation between them; for while cobalt and nickel are found in meteoric iron, and are like iron naturally magnetic, iron is always found in the ores of nickel and cobalt, often in large proportion. Again, there are traces of cobalt and nickel in the ores of manganese, except in a very few instances. Lastly, the atomic weight of all four metals is nearly the same, varying only from 27·6 to 29·6.

35. *Cobalt.*

Symbol Co. Equivalent = 29·5.

The metal is found chiefly as arseniuret, along with arseniurets of iron and nickel; also as sulphuret. It is best purified from arsenic by melting with sulphur and alkalies, when it is converted into sulphuret; or the arseniuret is dissolved in nitric acid, and the arsenic precipitated as sulphuret by hydrosulphuric acid, which does not precipitate cobalt, nickel, or iron in acid solutions; but this latter process is very tedious. When a solution is obtained free from arsenic it is boiled with nitric acid to convert the iron into sesquioxide. Excess of alkali is then added, and the precipitate, consisting of protoxides of cobalt and nickel, and sesquioxide of iron, is acted on by oxalic acid, which forms with the two first insoluble salts, with the last a soluble one. The iron is thus entirely removed by washing, and a pale pink powder is left, a mixed oxalate of cobalt and nickel, the former predominating. When the ore of nickel (arseniuret) is treated in the same way, the mixed oxalate is pale green, the nickel predominating. This powder is dissolved in liquor ammoniæ, and the dark red solution exposed to the air in a loosely-covered jar. As the excess of ammonia is dissipated, a green salt is deposited, oxalate of nickel and ammonia, while the colour of the liquid becomes a pure wine red, and it contains now only a similar but soluble double oxalate of cobalt and ammonia. This is dried up and ignited, or boiled with caustic potash, and yields pure black sesquioxide of cobalt. If the metal is wanted, this oxide is dissolved in hydrochloric acid, precipitated by a fixed alkali, and reconverted into oxalate, which is now of a pure pink colour, and when ignited in a covered crucible with a small aperture for gas, leaves the pure metal either spongy, or if the heat be high enough, melted into a button. The action of heat on the oxalate is as follows, $CoO, C_2O_3 = 2\ CO_2 + Co$. The oxalate of nickel and ammonia is ignited, and leaves oxide of nickel, from which the metal may be prepared exactly as cobalt is.

Cobalt is gray, brittle, very infusible—specific gravity 8500. Its protoxide CoO is a powerful base, has an ash-gray colour, and forms salts, which are either pink, crimson, or blue. Its solutions are pink, and give with alkalies a lilac hydrate, changing to brown; a permanent lilac carbonate with carbonated alkalies, and a black sulphuret with sulphuret of ammonium. Salts of cobalt, ignited with alumina, give it a fine smalt-blue colour. In fact smalt or zaffre is the silicate of oxide of cobalt, named zaffre (or sapphire originally, Italian *zaffir*) from its colour. It is got by roasting the ores of cobalt with sand, and is much used to give the blue colour to chinaware, and also to be added in small quantity to paper to improve its colour. There are several oxides of cobalt, but the protoxide is the most important.

The protochloride, $CoCl$, forms beautiful deep red crystals, which, when heated, melt to a deep rich blue liquid. Traces made on paper with a very dilute solution of this salt are invisible when dry, their pink colour being very pale. But on being warmed they turn blue and become visible, again disappearing on cooling, moisture being absorbed. This is one of the oldest and best known sympathetic inks, and has this advantage that the characters may be made to appear and disappear any number of times, provided the heat applied be not too strong.

36. *Nickel.*

Symbol Ni. Equivalent = 29·6.

The preparation of this metal has been given under cobalt. It is about as difficult to melt as iron, is of specific gravity 8800, has a whiter colour, and is malleable and magnetic, so that needles for the compass may be made of it, and these do not rust as steel is apt to do. But the metal is principally used as the chief ingredient in German silver. The more nickel this alloy contains, up to a certain point, the more it resembles silver in colour and lustre, as well as in permanence. The other ingredients are zinc and copper.

Protoxide of nickel, NiO, is a powerful base, its salts are all green, and their colour is complementary to that of the corresponding salts of cobalt. Its solutions are easily recognised by their colours, and by the pale apple-green hydrate and carbonate produced by caustic and carbonated alkalies. Ammonia in excess redissolves the precipitated hydrate, forming a sapphire-blue solution. Sulphuret of ammonium causes a black precipitate of the sulphuret NiS. From salts of copper, which are redissolved by ammonia, with a deep

violet-blue, and precipitated black by sulphuret of ammonium, those of nickel are distinguished by not being precipitated, if free acid be present, by hydrosulphuric acid, and by the action of ferrocyanide of potassium which gives with copper a chestnut-brown precipitate. The colour of the solution of copper too is generally blue.

Nickel forms a peroxide which is not of much interest, nor are the other compounds of nickel very important. The astonishing analogy between nickel and cobalt in so many points, while they differ in the colour of their compounds, as well as the fact that they always occur associated, and that they seem to accompany iron, not only in the mineral kingdom, but also in meteoric iron, and that both are magnetic, seem to indicate some hidden relations of an interesting kind.

37. *Tin.*

Symbol Sn (Stannum). Equivalent = 59.

This metal is the last of the present group, and stands here by itself, although it has many points of analogy with zirconium, and perhaps titanium, in its compounds.

Tin occurs chiefly as deutoxide or peroxide, sometimes called stannic acid, from its weak acid properties, in the form of rounded or water-worn crystals, called tinstone, or stream tin, being found in the beds of streams in tin districts. It is easily reduced by heating with charcoal, the metal being very fusible. Tin also occurs as tin blende or sulphuret, which is roasted and then heated with charcoal.

The metal has a yellowish-white colour and bright lustre, and melts at 440°. Its specific gravity is 7290. It is a most valuable metal, being used to make pipes and sheets or leaves, also to coat iron plate, forming tinned iron, commonly called tin-plate, and to form with copper the various kinds of bronze and bell metal; with lead, pewter and solder.

When heated to whiteness in air, it burns into oxide. and may also be easily oxidized by nitric acid. It forms two oxides—the protoxide $Sn\,O$, a somewhat weak base, and the deutoxide $Sn\,O_2$, which has rather weak acid properties. Peroxide of tin, or stannic acid, seems to exist in two forms; in one it dissolves easily in acids, in the other it is insoluble. The latter is supposed to have 5 times the equivalent of the former, and to be $Sn_5\,O_{10}$.

There are two chlorides corresponding to the two oxides, $Sn\,Cl$ and $Sn\,Cl_2$, both of which are much used in dyeing and calico-printing to brighten the colours. It is only by means of tin that cochineal is made to yield the fine colour given to scarlet cloth. The protochloride of tin crystallizes very readily. The perchloride is a volatile fuming liquid, but is commonly prepared in aqueous solutions by dissolving tin in nitro-hydrochloric acid. The protochloride is formed when tin is heated with hydrochloric acid, hydrogen being disengaged.

Iodide of potassium strikes a deep red colour with salts of tin, from the formation of an iodide.

There are two sulphurets of tin. The protosulphuret $Sn\,S$, is dark brown or black. The bisulphuret has a dirty yellow colour, and some degree of metallic lustre; it used to be called aurum musivum. These sulphurets are precipitated from the solutions of tin by hydrosulphuric acid.

Tin is thrown down in beautiful metallic crystals, from its solutions, by zinc.

GROUP VI.

Acidifiable Metals.

The next group of metals is characterized by a remarkable tendency to form acids with oxygen, and by the absence of basic protoxides. They are eleven in number, but only three of them are of practical importance, and one or two of the others are hardly known. Most of the acids of this class of metals are teroxides, and most of the metals form volatile chlorides.

38. *Chromium.*

Symbol Cr. Equivalent = 26·7.

This metal, which is in some points analogous to iron and manganese, connects this group with the last. It is chiefly found in two forms, as chromic acid, combined with oxide of lead, in the beautiful and scarce red lead ore of the Ural, and as sesquioxide, combined with sesquioxide of iron in the more abundant chrome iron ore. The metal is little known. It is very infusible, hard, and brittle. Specific gravity about 6000.

It forms two oxides—the sesquioxide or green oxide, $Cr_2\,O_3$, and the orange-red chromic acid, $Cr\,O_3$. The former, like other sesquioxides, is a weak base. It is obtained from bichromate of potash, by heating it with carbonate of soda and sal-ammoniac, when the acid is deprived of half its oxygen by the hydrogen of the ammonia. Water dissolves the saline matter from the residue, and leaves the sesquioxide of a fine deep green. It is precipitated from its solutions as a bluish-green bulky hydrate. Like all sesquioxides, it has a great tendency to form double salts, and in fact may be substituted for alumina in alum without altering the form of the salt. Chrome alum, as it is called, is of a dark reddish-purple by transmitted light, black by reflected light, green in powder and in solution, of a mixed green and red by day-light, pure red by candle-light. Another beautiful double salt, the oxalate of chromium and potash, is azure-blue by transmitted sun-light, red by transmitted candle-light, black by reflected light. The remarkable action of these salts on light has been described by Brewster.

Chromic acid, $Cr\,O_3$, is formed when chrome iron ore is heated with nitre. The sesquioxide, being oxidized, forms the acid, which unites with the potash of the nitre, forming a lemon-yellow neutral chromate, $KO,\ Cr\,O_3$. The strong solution of this salt, mixed with nitric acid, loses half its potash, and deposits beautiful orange red crystals of the bichromate of potash, $KO,\ 2\ Cr\,O_3$. Both these salts are much used in calico-printing. To obtain the acid pure, a cold saturated solution of bichromate is mixed with oil of vitriol; and the mixture, on cooling, for heat is developed, deposits beautiful red acicular crystals of the acid. These are drained on a fire-brick, excluding the air, and when dry, sealed up in a tube. If any sulphuric acid or bisulphate of potash adhere to them, they may be purified by dissolving them in a little hot water, adding some sulphuric acid, and recrystallizing.

Chromic acid is very soluble in water, even deliquescent. It oxidizes organic substances, such as alcohol or ether, with flame. One very convenient method of using it as an oxidizing agent is to heat the organic substance with bichromate of potash and sulphuric acid, when the action is more gentle. In all cases the acid is reduced to sesquioxide.

The salts of chromic acid are remarkable for their fine colours, which are yellow, orange, and red. The chromates of potash (neutral), baryta, zinc, and lead (neutral), are of various shades of yellow. The bichromate of potash is orange. The dichromate of lead and the chromate of mercury are orange-red, and that of silver is deep red. The chromates of lead are used as pigments, and also formed on the cloth in calico-printing. The sesquioxide is used to give the beautiful green now so often seen on fine porcelain.

The chromates of potash are poisonous, and the workmen who make or use them suffer from ulcers on the hands of a peculiar kind. The solutions of these salts are antiseptic in a high degree. They may also be used like nitre to give to cotton or cloth the property of burning as in moxas.

There are two chlorides of chromium, a sesquichloride, which is of a peach-blossom colour, but forms a green solution and a volatile chloride, either a terchloride $Cr\,Cl_3$ or $Cr_2\,Cl_7$. But the latter is not well known. There is an oxychloride which is a volatile liquid of a dark red colour, acting violently on combustible substances, which is $Cr\,O_2$

Cl, that is, chromic acid, in which 1 eq. of oxygen is replaced by chlorine, or else $2\ Cr\,O_3 + Cr\,Cl_3$, a compound of 2 eqs. of chromic acid with 1 eq. of terchloride. The proportions are the same, the latter being 3 times the former.

39. *Vanadium.*

Symbol V. Equivalent = 68·6.

This very rare metal is found as vanadic acid $V\,O_3$, combined with oxide of lead, and also in small proportions in some of the ores of iron. It forms three oxides, a protoxide $V\,O$, a deutoxide $V\,O_2$, and vanadic acid $V\,O_3$, which is analogous to chromic acid. The acid has a reddish orange colour, is sparingly soluble in water, and when fused forms on cooling very large crystals even from a small quantity. It is easily deoxidized and yields the deutoxide, which is a weak base, and forms blue salts. The protoxide is black, and is not known to form salts. Vanadium forms two chlorides, a bichloride $V\,Cl_2$, and a volatile terchloride $V\,Cl_3$. Vanadium is too rare to be applied to any useful purpose.

40. *Molybdenum.*

Symbol Mo. Equivalent = 46.

This metal occurs as molybdic acid, combined with oxide of lead, and also as tersulphuret of molybdenum. The metal is little known. Molybdic acid, $Mo\,O_3$, corresponds to chromic acid. Its only use is as a test for phosphoric acid, with which, when heated in solution with it, it forms a peculiar yellow precipitate. It is used in the form of molybdate of ammonia.

Like chromium, molybdenum forms a volatile terchloride and an oxychloride. But we need not dwell on this metal here. There is an oxide, with less oxygen than the acid, which has a fine blue colour.

41. *Tungsten.*

Symbol W (Wolfram). Equivalent = 95.

This metal is of no great interest. It is found as tungstic acid, combined with lime, or with oxides of iron and manganese, the former being the mineral tungsten, the latter wolfram.

Tungstic acid, $W\,O_3$, is a nearly insoluble yellow powder. Like molybdenum, it forms, with less oxygen than in the acid, a blue oxide like indigo. This appears to be a compound of the acid with another inferior oxide, oxide of tungsten, which is black. Tungsten, too, forms a volatile terchloride, and an oxychloride.

42. *Titanium.*

Symbol Ti. Equivalent = 25.

This metal also occurs as titanic acid in the mineral rutile. According to some, the formula of the acid is $Ti\,O_3$, while others make the acid $Ti\,O_2$. From its analogy to oxide of tin, it is probable that the latter formula is correct. Like peroxide of tin, it exists in two forms, one of which is brown and insoluble in acids; the other white and soluble in hydrochloric acid. The white variety is used to form an enamel for artificial teeth. It was at one time thought that the copper-coloured cubic crystals occasionally found in the slag of iron furnaces, were metallic titanium; but these have been shown to contain nitrogen and cyanogen besides. This metal, like the two preceding, forms a volatile chloride. There appear to be two oxides, the sesquioxide and the acid, and two chlorides, sesquichloride and bichloride, corresponding to these. The solutions of titanic acid in acids are decomposed by boiling, the titanic acid being deposited; and when the acid is fused with alkalies, the fused titanate is decomposed by water, leaving an acid salt with large excess of acid.

The composition and properties of the acid and of the bichloride show a great analogy with tin; but these metals are easily distinguished, since the compounds of tin, heated on charcoal before the blowpipe, readily yield metallic tin.

43. *Columbium.*

Symbol Ta (Tantalum). Equivalent = 92 ?

This metal occurs in the form of columbic acid, $Ta\,O_3$, in a few very rare minerals. Its properties are but imperfectly known; and it has recently been found to be associated with two other analogous metals, namely, 44. Niobium, and 45. Pelopium, which are still less known, but appear also to form acids with oxygen.

46. *Antimony.*

Symbol Sb (Stibium). Equivalent = 129.

This metal occurs as sulphuret, and as double sulphuret of antimony and silver; also as bournonite, a triple sulphuret of lead, copper, and antimony. It is obtained from the sulphuret by heating it with iron filings, or with carbonate of soda, after roasting it. The metal is fusible at a moderate red heat, of a gray colour and very bright lustre; specific gravity 6800. At a white heat it is converted into vapour, and burns in air. It forms two distinct oxides, and these combine to form a third.

Teroxide of antimony, $Sb\,O_3$, is a weak base. It is obtained by pouring the terchloride into water, when an oxychloride is formed. This is boiled with excess of carbonate of soda, and leaves the teroxide as a grayish-white powder. It has a great tendency to form double salts, such as tartar emetic, which is a tartrate of antimony and potash. Its solutions give with hydrosulphuric acid a characteristic brownish-orange precipitate of hydrated tersulphuret.

Antimonic acid, $Sb\,O_5$, is obtained by the action of nitric acid on the metal; it resembles the teroxide in appearance, but has weak acid properties. Both oxides are used in medicine.

There is another oxide, sometimes called quadroxide, but which appears to be $Sb_2\,O_8 = Sb\,O_3,\ Sb\,O_5$, an antimoniate of the teroxide. It is formed by heating the antimonic acid.

Antimony forms with hydrogen a gaseous compound, probably $Sb\,H_3$, analogous to phosphuretted hydrogen. It is not yet known in a state of purity, but only mixed with hydrogen. It is formed when hydrogen is disengaged in a solution containing antimony. The mixed gas burns with a yellow flame, giving off fumes of oxide, and which deposit metallic spots of antimony on glass or porcelain held in the flame. In these characters, antimony agrees with arsenic, and, indeed, it may be said to form with phosphorus and arsenic a group of three, like some of those we have already seen.

There are two chlorides of antimony, the terchloride, $Sb\,Cl_3$, and the perchloride, $Sb\,Cl_5$, both volatile; the former semi-solid at ordinary temperatures, and hence called butter of antimony. Mixed with water, it deposits an oxychloride, $Sb\,Cl_3 + 2\ Sb\,O_3$, called powder of algaroth, which is used in preparing the oxide as well as tartar emetic. The terchloride is formed by the action of hydrochloric acid on the tersulphuret.

There are also two sulphurets, the tersulphuret $Sb\,S_3$, and persulphuret $Sb\,S_5$; the former is the ore of antimony, and is dissolved by hydrochloric acid, yielding the terchloride and hydrosulphuric acid gas, $Sb\,S_3 + 3\ H\,Cl = Sb\,Cl_3 + 3\ HS$.

The compounds of antimony are much employed in medicine; and the metal is a chief ingredient in the alloy used for types, in which it is combined with lead and a little tin, and in some alloys with tin used for various purposes.

47. *Arsenic.*

Symbol As. Equivalent = 75.

This metal is found chiefly combined with sulphur, and also

with metals, such as cobalt and nickel. It likewise occurs as arsenic acid, As O_5, combined with various oxides. When the minerals containing it are roasted, part of it is sublimed in the metallic state, and part as arsenious acid As O_3, which is consequently obtained in very large quantities from the ores of cobalt and nickel. To obtain the metal from this acid, it is simply heated with charcoal, when the metal sublimes and forms a bright metallic crust. Its density is 5800. Under the ordinary pressure, it is converted into vapour before reaching its melting point. Its vapour has a strong garlic odour, and is very poisonous. It burns when heated in air, forming arsenious acid, which also sublimes as a white crystalline powder.

Arsenious acid, As O_3, is volatile; its vapour has no smell, unless when heated on charcoal, when it is reduced to the metallic state, and it is the metallic vapour the smell of which is then observed. It is sparingly soluble in water, and its solution gives, with excess of lime-water, a white precipitate of arsenite of lime; with ammoniaco-sulphate of copper, a grass-green precipitate of arsenite of copper, or Scheele's green; with ammoniaco-nitrate of silver, a lemon-yellow precipitate of arsenite of silver; and with hydrosulphuric acid, a bright yellow sulphuret, As S_3. By these characters this substance when pure is easily recognised; and from its very poisonous nature, and the facility of procuring it, poisoning by its means is so frequent, that it has to be sought for oftener than any other poison.

The best antidote to it is the administration of a large quantity of moist hydrated sesquioxide of iron, which has the property of forming with it an insoluble and inert arsenite of iron. Calcined magnesia has a similar effect.

When arsenious acid has to be sought for in mixed fluids, the above tests are inapplicable, except the last, which may be used to separate the arsenic from the mixed fluid, after adding an acid and filtering. The impure sulphuret thus obtained is decomposed by heating it with a mixture of charcoal and carbonate of potash, or with cyanide of potassium, and the metal sublimed. It is recognised by its volatility and the odour of its vapour, but it may also be oxidized and the tests applied. Even when the acid is pure, we ought always to reduce at least a part of it to metal, as the most characteristic property. Only antimony at all resembles it in this particular, but we shall see presently that these two metals are easily distinguished.

Where the quantity of arsenic present is very small, the method of Marsh, in which it is converted into arseniuretted hydrogen, must be employed as the most delicate and the most certain. We shall describe this presently, under the head of arseniuretted hydrogen.

Arsenic acid, As O_5, corresponds to phosphoric acid as arsenious acid does to phosphorous acid. It is formed by heating arsenious acid with nitric or nitro-hydrochloric acid. It is very soluble, very acid, and very poisonous. Its salts are exactly similar to and isomorphous with those of phosphoric acid.

When hydrogen is disengaged in a solution containing arsenious acid, there is formed arseniuretted hydrogen, As H_3, mixed with hydrogen. The gas is obtained purer, but still mixed with some hydrogen, by the action of hydrochloric acid on an alloy of tin and arsenic. It has a most offensive alliaceous smell, and burns when heated in air, with a pale flame, producing arsenious acid and water. It is extremely poisonous, and several chemists have lost their lives from incautiously inhaling a little of it.

When this gas, even mixed with a large excess of hydrogen, is passed through a tube, part of which is red-hot, it is entirely decomposed, and a ring of metallic arsenic is deposited just beyond the hot part of the tube. On this property is founded Marsh's process for detecting arsenic.

The suspected liquid is added to diluted sulphuric acid, and zinc is introduced. The gas is then passed through a narrow tube, and a slow but constant current of it is kept up. As soon as all the air is expelled from the tube, a part of it is heated to redness, and if there be but a trace of

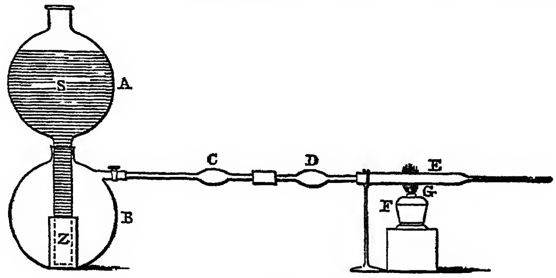

Fig. 30.

arsenic present, a ring soon appears. Or the gas may be burned at the end of the tube without heating it in the tube, and a cold piece of glass or porcelain held in the flame, which, if arsenic be present, will deposit metallic stains of that metal. The former method is the best, as the whole arsenic may in time be collected in one ring. Under similar circumstances, antimony also forms a ring of metal, but the arsenical ring is sublimed by a moderate heat, and if air be present is changed into arsenious acid, easily recognised by its octahedral crystals, its volatility, and by other tests. The antimony is with difficulty volatilized, and if oxidized, the oxide remains, and is not crystalline. Nitric acid dissolves the arsenic, but not the antimony.

This method of detecting arsenic is so delicate, that by its means arsenic is found where it was not before suspected. We often find it in the commercial sulphuric acid, hydrochloric acid, and zinc, the very substances we use in the process. Hence, before introducing the suspected fluid, we must always try the acid and zinc first for a time. If no ring appear, and if, on adding the suspected liquid, the ring be at once formed, we may safely conclude that the arsenic comes from that liquid. But without this precaution, we dare not make any such statement.

There is only one chloride of arsenic, a terchloride, As Cl_3, which is volatile.

There are three sulphurets of arsenic. Realgar, which is reddish-brown, As S_2; orpiment, which is yellow, As S_3; and the persulphuret, which is pale yellow, As S_5. The two former are found in nature.

The reader has no doubt remarked the analogy between the chemical relations of antimony and arsenic and those of phosphorus. Indeed, no two elements are so analogous in this respect as arsenic and phosphorus, save that one is metallic, the other not. There is a resemblance, however, even in physical properties for the odour of phosphorus closely resembles that of arsenic. These three elements, in spite of one being non-metallic, form a group distinguished by forming oxides with 3 and 5 eqs. of oxygen, and gaseous compounds of a fetid odour with 3 eqs. of hydrogen.

48. *Tellurium.*

Symbol Te. Equivalent = 64·2.

This metal forms one of another remarkable group of three, the two others being non-metallic, namely, sulphur and selenium. This case and the preceding, show that there is no essential and absolute division between metals and non-metallic bodies.

Tellurium is found, but very rarely, combined with gold, silver, lead, and bismuth, in the Transylvanian mines. In appearance it resembles antimony, and its specific gravity is 6260. With oxygen it forms two acids, tellurous acid, Te O_2, and telluric acid, Te O_3, corresponding to sulphurous and sulphuric acids.

With hydrogen, it forms a gaseous compound, H Te, corresponding to hydrosulphuric acid, and resembling it in its properties and its action on metallic solutions.

Tellurium is volatilized by an intense white heat. It is chiefly interesting from its analogy to sulphur and selenium; but its rarity prevents it from being applied to useful purposes, although it seems likely to have a powerful action on the animal system.

GROUP VII.

This group has no peculiar character, from which it can be properly named, but is intermediate between group 5 and the next or last group, that, namely, of the noble metals. The number of metals in it is five, namely, bismuth, uranium, copper, lead, and mercury. Their attraction for oxygen is less than that of the metals of group 5, but still considerable. The oxides of one of them, mercury, are reduced by heat alone, thus connecting these metals with the noble metals. The protoxides, and in some cases higher oxides, are basic.

49. *Bismuth.*

Symbol Bi. Equivalent = 71 ? or 106 ?

This metal is found in the metallic state, and as sulphuret, also combined with tellurium. It is obtained entirely from the native metal, which, being very fusible, is separated from its gangue or matrix by fusion. It contains a little sulphuret, also sulphurets of other metals and arseniurets, but is easily purified by heating with $\frac{1}{8}$th of its weight of nitre. The sulphur, arsenic, and other metals are oxidized and combine with the potash, as does also a little bismuth; the rest forms a pure button of metal below the saline mass. Bismuth is very crystalline, and may be obtained in fine crystals by melting a mass of it, and when it is half solidified, breaking the crust and pouring out the liquid part. The hollow mass is found lined with fine hollow rhombohedral crystals, not far removed from the cube in their angles. Its colour is reddish-white; its specific gravity 9900. It melts at about 507°, and expands in solidifying. It is volatile at a very intense heat.

Bismuth forms two oxides: 1. A basic oxide, which is thought by some to be a protoxide, $Bi\,O$, in which case the equivalent of the metal is 71; but which others regard as a sesquioxide, Bi_2O_3, which makes the equivalent of the metal 106. It is a weak base, and its salts are decomposed by water, which dissolves very acid salts, leaving insoluble subsalts. This is particularly the case with the nitrate, which, diluted with water, deposits a fine white crystalline powder of subnitrate, used as a white paint for the face. It is, however, very liable to be blackened by hydrosulphuric acid and other analogous compounds of sulphur. The salts of bismuth are recognised by the action of water and that of hydrosulphuric acid.

2. A peroxide, which has weak acid properties, and is also called bismuthic acid. It has a light red colour, and has not been much studied. If the basic oxide be Bi_2O_3, the acid is Bi_2O_5; but if the former be $Bi\,O$, the latter is probably $Bi\,O_2$. There seems to be an intermediate oxide, a compound of the acid with the base.

Chloride of bismuth is volatile, and, taking the larger equivalent, its formula is Bi_2Cl_3. It dissolves in hydrochloric acid, but the solution is decomposed by water, which throws down an oxychloride, $Bi_2\,Cl_3 + 2\,(Bi_2O_3,\,3\,HO)$. This powder is pearl white, used like the subnitrate as a cosmetic.

Sulphuret of bismuth, Bi_2S_3, occurs in nature, and is isomorphous with sulphuret of antimony.

Bismuth forms with lead and tin alloys of remarkable fusibility. That with 1 part of lead, 1 of tin, and 2 of bismuth, melts at 201°; that with 5 parts of lead, 3 of tin, and 8 of bismuth, melts at 209°. These alloys are used for taking casts for electrotyping, and for various other purposes.

50. *Uranium.*

Symbol U. Equivalent = 217·2.

This metal is found as an oxide, combined with oxides of iron, lead, copper, and other metals, along with silica, in the mineral pitchblende; and also as a phosphate of uranium and lime, in uranite. The pitchblende is acted on by nitric acid, and the solution purified from lead, copper, and arsenic, by hydrosulphuric acid. The nitrate of uranium is then crystallized. This salt, which forms beautiful yellow crystals with green reflection, when heated leaves an oxide. This, mixed with charcoal, and heated in a current of chlorine, gives a volatile protochloride, U Cl, in dark green crystals. These, heated with potassium, yield the metal as a black powder, parts of which, by the heat evolved, are brought into a compact state, and exhibit a silvery lustre. Heated in air, it burns vividly, producing the oxide. It is permanent at ordinary temperatures, and appears to be in some degree malleable. It only decomposes water at a high temperature.

Uranium forms two oxides, both basic, a protoxide, U O, and a sesquioxide, $U_2\,O_3$. The former is dark brown, and forms green salts; the latter is yellow, and forms beautiful yellow salts. From the circumstance that the salts of the sesquioxide differ in the amount of acid from those of all other sesquioxides—the sulphate, for example, being $U_2\,O_3,\,SO_3$, and not like that of alumina, $Al_2O_3,\,3\,SO_3$—it is supposed that the sesquioxide is really a protoxide, not of uranium, but of uranyle, $U_2\,O_2$. On this supposition, the salts of the sesquioxide are no longer anomalous. These salts give yellow precipitates with the alkalies, which are compounds of the sesquioxide with the alkalies, for that oxide has both weak acid and weak basic properties. Ferrocyanide of potassium produces in the salts of sesquioxide of uranium a fine rich brown precipitate.

The chloride, U Cl, has been already mentioned. There is an oxychloride $U_2\,O_2\,Cl$, which may be regarded as the protochloride of uranyle. When heated with potassium it leaves not the metal but the protoxide, UO, or uranyle $U_2\,O_2$, which was long supposed to be the metal, and appears, in fact, to play the part of a metal.

Oxide of uranium is now much used to give to glass the beautiful yellow colour, with green reflection, so much admired in the Bohemian glass.

51. *Copper.*

Symbol Cu. Equivalent = 31·7.

This valuable metal occasionally occurs native, but its chief ores are the mixed sulphurets of iron and copper or copper pyrites, the carbonate or blue copper ore, and the compound of carbonate and hydrate called green malachite. The latter are easily reduced by heating with charcoal; the former is roasted so as to oxidize it and dissipate the sulphur, and the roasted ore is then heated with charcoal. This process is repeated, and at last pure copper is obtained. Another ore of copper, very easily worked, is the red oxide or suboxide. Lastly, in mines where sulphuret of copper is present, it is oxidized by the air into sulphate of protoxide, which is dissolved by the water filtering through the rocks. This water, where the sulphate is observed, is collected in reservoirs, and the copper precipitated by fragments of iron. The copper thus obtained is very pure, and has only to be melted.

Copper has a bright red colour and high lustre, of specific gravity from 8780 to 8960. It melts at a strong red heat, and at a white heat gives vapours which burn with a green flame. It is very malleable and ductile, and has much tenacity.

Copper is rapidly tarnished and covered with a green rust

or verdigris, in moist air. At a red heat it is rapidly converted into the black protoxide.

Protoxide of copper, $Cu\ O$, is black, and forms with acids blue or green salts, with water a blue hydrate. It is a pretty strong base. Its solutions are known by their colour, by the action of a rod of iron which is quickly covered with precipitated copper, and by the action of ammonia which first causes a pale blue precipitate of subsalt or hydrate, and when added in excess, redissolves this, forming a deep violet-blue solution. Potash and soda throw down the blue hydrate, which, when boiled, loses water and becomes black. Hydrosulphuric acid gives a black precipitate of sulphuret, and ferrocyanide of potassium gives, in acid solutions, a chestnut-brown precipitate. The last is a most delicate and characteristic test, and by its means traces of copper have been found in most soils, as well as in plants, and in animal and vegetable food. Copper vessels are rapidly corroded by cold vegetable acids, but the same acids may be boiled in them without corroding the metal. As the salts of copper are very poisonous, this must be carefully attended to. Preserves of acid fruits, such as red currants, &c., are constantly boiled in vessels of copper, but must not be allowed to cool in them. Copper is sometimes improperly added to pickles to improve their green colour. Its presence is easily detected in the acid liquor by the ferrocyanide, or by introducing the blade of a knife. Several of the salts of copper are used in medicine. Sulphate of copper, or blue vitriol, is an escharotic externally, and an emetic in small doses given internally. The violet-coloured ammoniaco-sulphate of copper is used in epilepsy, and also as a test for arsenious acid.

Suboxide of copper, $Cu_2\ O$, is red and crystallizes in octahedrons. It is found in nature, and may be formed by heating the protoxide with copper filings, or by adding to a solution of sulphate of copper sugar and potash, till the precipitate at first formed is redissolved. On boiling, the suboxide is deposited as a fine deep red crystalline powder. It forms colourless salts, and a colourless solution in ammonia, but the latter solution absorbs oxygen from the air, and becomes violet-blue. The oxide gives to glass, when melted with it, a fine red colour.

Copper seems to form two oxides with more oxygen than the protoxide, a deutoxide and an acid. But these are very little known.

There are two chlorides of copper; the subchloride or dichloride $Cu_2\ Cl$, and the protochloride $Cu\ Cl$. The former is white and sparingly soluble. The latter is green and very soluble. It is formed by dissolving the protoxide in hydrochloric acid.

There are also two sulphurets corresponding to the two oxides and chlorides. The disulphuret, $Cu_2\ S$, is formed by melting together copper and sulphur. It is fusible and crystalline. The protosulphuret, $Cu\ S$, is the black precipitate produced in salts of copper by hydrosulphuric acid. $H\ S + Cu\ O,\ S\ O_3 = H\ O,\ S\ O_3 + Cu\ S$. It rapidly attracts oxygen from the air, and is converted into sulphate. Copper pyrites consists of the disulphuret, combined with sesquisulphuret of iron, and mixed moreover with iron pyrites, or bisulphate of iron. From this mineral the greater part of the copper of commerce is obtained.

Copper forms many valuable alloys. With zinc or zinc and a little tin or lead, it forms brass; with tin it gives bronze, bell metal, gong metal, and gun metal, according to the proportions. In the bronze used for medals, a trace of zinc is added.

52. *Lead.*

Symbol Pb (Plumbum). Equivalent = 103·7.

This valuable metal occurs in various forms, but the only ores which are wrought are galena or sulphuret of lead, $Pb\ S$, and carbonate of lead, $Pb\ O,\ CO_2$. The latter is simply heated with charcoal. The former is roasted, when sulphurous acid is given off, and oxide of lead, $Pb\ O$, and sulphate of lead, $Pb\ O,\ SO_3$, are formed. A part of the ore is left unchanged; and on increasing the heat, a most remarkable reaction takes place between the unaltered ore and the oxide and sulphate. The reaction with the oxide is this: $Pb\ S + 2\ Pb\ O = SO_2 + Pb_3$. With the sulphate it is this: $Pb\ S + Pb\ O, SO_3 = 2\ SO_2 + Pb_2$. In both cases, metallic lead and sulphurous acid are the only products. When the ore is less pure, it is first roasted and then heated with iron, which removes the sulphur. The lead thus obtained frequently contains silver in sufficient quantity to repay its extraction.

Lead is a metal of a dark-gray colour and high lustre, quickly tarnished in air, but only superficially at ordinary temperatures. It is very soft, malleable, and ductile, but has little tenacity. Its specific gravity is 1144. It is easily melted, and when hot is rapidly oxidized, forming protoxide. The uses of lead are well known.

With oxygen lead forms three compounds, a suboxide $Pb_2\ O$, a protoxide $Pb\ O$, and a deutoxide having feeble acid properties, peroxide of lead or plumbic acid.

The protoxide, $Pb\ O$, is formed when lead is heated rather beyond its melting point. It is a yellow powder called massicot. This, heated more strongly, melts, and on cooling forms a crystalline brownish-yellow mass, called litharge. Heated for a long time in air, massicot takes up oxygen and forms the red oxide or minium, a compound of plumbic acid with the protoxide. The protoxide is a strong base, isomorphous with baryta and lime. Its salts have a sweet taste, and are poisonous, more especially the carbonate. They are recognised by the following tests. Alkalies throw down a white hydrate, soluble in excess; carbonated alkalies a white carbonate; hydrosulphuric acid a black sulphuret; sulphuric acid and sulphates a white insoluble sulphate; and iodide of potassium a bright yellow crystalline iodide. The most important of its salts are the carbonate or white lead, the nitrate, the acetates, which are used in calico-printing, the latter also extensively in medicine, and the chromate, valued for its fine yellow colour.

Plumbic acid or peroxide of lead is obtained by acting on red lead with nitric acid. Red lead is $Pb_3\ O_4 = 2\ Pb\ O,\ Pb\ O_2$ and also $Pb_4\ O_5 = 3\ Pb\ O,\ Pb\ O_2$. The acid dissolves out the protoxide, and leaves the plumbic acid as a puce-coloured dense powder. It combines with bases, and even forms crystallizable salts with some of them.

With chlorine, lead forms but one compound, a protochloride, $Pb\ Cl$. It is formed as a sparingly soluble white crystalline powder when hydrochloric acid or soluble chlorides are added to the salts of lead. The chloride, melted with the oxide, forms several oxychlorides, which are used as yellow pigments, under the names of mineral yellow, Turner's yellow, &c.

There is but one iodide, $Pb\ I$, formed when iodide of potassium is added to a salt of lead. It is a bright yellow sparingly soluble powder, generally formed of minute scales, which dissolves in boiling water, forming a colourless solution. On cooling, large and beautiful scales of a golden lustre are deposited. They are regular hexagons.

There is also but one sulphuret, $Pb\ S$, formed as a black powder when hydrosulphuric acid or a soluble sulphuret acts on salts of lead. It is the same substance with galena, the ore of lead, which forms cubic crystals of a metallic lustre, but very brittle.

Lead forms with antimony the alloy used for type metal; with tin it forms pewter and various kinds of solder.

53. *Mercury.*

Symbol Hg (Hydrargyrum). Equivalent = 200.

This metal is found native, and in the form of bisul-

phuret or cinnabar. The latter substance, when heated in iron bottles with iron filings, yields metallic mercury. The metal is liquid at all temperatures from $-39°$ to about $600°$, which is its boiling point. Below $-39°$ it is solid. It has a bluish-white colour and bright lustre. Its specific gravity is about 1300. When heated to about its boiling point, in air, it absorbs oxygen, and forms the red oxide or deutoxide, which is again decomposed by a temperature somewhat higher.

Mercury forms two oxides, a protoxide and a deutoxide. The protoxide, HgO, is obtained by the action of potash on calomel, which is the protochloride, $HgCl + KO = KCl + HgO$. It has an ash-gray colour, and by the action of light is resolved slowly into deutoxide and metal, $2\,HgO = HgO_2 + Hg$. It is a base, and its salts give a dark gray or black precipitate with alkalies, a white one of calomel with hydrochloric acid or soluble chlorides, and a dirty greenish-yellow protoiodide with iodide of potassium. They are reduced to the metallic state by copper and by other metals; also by protochloride of tin, which first forms calomel and then reduces it.

The peroxide or deutoxide, HgO_2, is also a base. It is obtained by heating the nitrate of either oxide till the acid is entirely expelled, taking care not to decompose the oxides. It is a very dark red, nearly black while hot, and light red when cold. The same oxide is formed slowly when mercury is kept at its boiling point in a vessel with a long neck, in which the vapours are condensed and fall back. Prepared in this way it is of a darker red, and is called oxidum hydrargyri rubrum per se, while that from the nitrate is called oxidum hydrargyri rubrum per acidum nitricum. The latter generally contains some subnitrate, and is more active as an escharotic. It is much used also in the form of ointment. Its salts give a yellow precipitate of hydrated peroxide with potash; a white with ammonia, which is a compound containing amide; and a fine scarlet periodide with iodide of potassium. Both the salts of protoxide and those of peroxide give a black precipitate with hydrosulphuric acid, which in the latter case is the bisulphuret, in the former a mixture of bisulphuret with the metal. The salts of the peroxide are reduced by the same reagents as those of the protoxide; by copper and other metals, by protochloride of tin, and by formic acid.

Mercury forms two chlorides; calomel, which is the protochloride, $HgCl$, a white, insoluble, heavy powder, formed by the action of hydrochloric acid or chloride of sodium on salts of the protoxide; and corrosive sublimate or bichloride, $HgCl_2$, which is formed when hydrochloric acid acts on the peroxide, $2\,HCl + HgO_2 = 2\,HO + HgCl_2$. It is a crystalline heavy substance, soluble in water, and very poisonous. The chlorides are also formed by subliming a mixture of sulphate of peroxide with common salt, which gives a sublimate of bichloride, and, if metallic mercury be added, calomel. Both are volatile, and calomel, whichever way prepared, always contains at first some bichloride. To render it fit for medical use, this must be removed by repeated boiling with water, as long as potash causes a yellow precipitate in the filtered liquid. Both chlorides are much used in medicine, calomel being the milder, and corrosive sublimate the more active of the two.

There are two bromides and two iodides, corresponding to the two chlorides. The iodides are formed by the action of iodide of potassium on the salts of the two oxides. The protoiodide, HgI, is of a dirty yellowish green, insoluble, and is resolved by light into periodide and metal, $2\,HgI = HgI_2 + Hg$. The periodide is of a beautiful scarlet, and insoluble, or nearly so. A moderate heat renders it lemon-yellow, and the yellow form is instantly reconverted into the red by friction, or by the touch of a hard point. In the latter case, the part touched becomes red, and the red colour spreads from it through the mass. The change of colour is owing to a change of position in the molecules, or a change of crystalline form. Both iodides are used in medicine, and the periodide also as a pigment.

Mercury rubbed with 1 eq. sulphur, forms a black powder called ethiops mineral, which is a mixture of the metal with the bisulphuret. With 2 eqs. of sulphur it forms the bisulphuret, which is also produced by the action of hydrosulphuric acid on salts of the peroxide. It is black when thus prepared; but if sublimed becomes dark red, and when finely powdered this acquires the colour of vermilion, which is a form of the bisulphuret.

The compounds of mercury with other metals are called amalgams. They are sometimes liquid, oftener semisolid. Amalgam of silver occurs native in crystals. Amalgam of tin is used for silvering the backs of mirrors, and an amalgam of tin and zinc for rubbing the cushion of electrical machines.

GROUP VIII.

The Noble Metals.

The metals of this group are so called, because, from their small attraction for oxygen, they do not tarnish in the air, nor even in the fire. Hence their use for ornamental purposes, and for coinage. They are eight in number, namely, silver, gold, platinum, and five rarer metals associated with platinum.

54. *Silver.*

Symbol Ag (Argentum). Equivalent = 108.

This beautiful metal is found native; also combined with sulphur, arsenic, and antimony, with tellurium, and with chlorine. It occurs also frequently in small but available quantity in galena or lead ore. Native silver, when disseminated in the rock, is extracted by amalgamation with mercury.

Silver has a pure white colour and brilliant lustre. Its specific gravity is about 10,500. It melts at a strong red or white heat, and is quite unaltered in the fire. By the intense heat of the galvanic battery it is volatilized. It is very malleable and ductile, and has considerable tenacity. It is rather soft, and therefore copper is added to form standard silver, which is hard, and wears better. Spanish dollars consist of pure silver, with only a trace of gold, which is present more or less in all silver.

Silver appears to form three oxides; a suboxide, Ag_2O, little known; the protoxide, AgO, a strong base, and a deutoxide or peroxide, AgO_2. The protoxide alone is of interest. It is obtained by adding potash to nitrate of silver, as a brown hydrate, which, when gently heated, loses water, and leaves the protoxide as an olive-coloured powder. Its salts are recognised by the brown precipitate produced by potash, which like nearly all compounds of silver dissolves in ammonia, by the curdy white chloride produced by hydrochloric acid or soluble chlorides, and by the black sulphuret thrown down by hydrosulphuric acid. The metal is reduced by copper, zinc, and iron, and even by mercury.

There is only one chloride, $AgCl$, which appears as a curdy white substance, insoluble in water and acids, soluble in ammonia, when hydrochloric acid or chloride of sodium is added to the salts of silver. It is fusible, and on cooling forms a semitransparent mass, called horn silver. It is blackened by light, a character common to all the compounds of silver, especially the chloride, iodide, bromide, &c.; on this property is founded the daguerreotype. The chloride, moistened with diluted acid, is reduced by zinc or iron; or it may be boiled with potash and sugar, or ignited to whiteness with lime and a little charcoal, when a button of silver is obtained.

The bromide and iodide resemble the chloride, but the iodide is yellowish and sparingly soluble in ammonia.

The sulphuret is black. It is found in nature both pure

and combined with arseniuret and antimoniuret of silver, also in galena with sulphuret of lead.

The chief uses of silver are for coinage and for plate. Nitrate of silver is used as a caustic and also internally, and the chloride, iodide, and bromide, are the substances used in photography in the form of a film on the surface of silver, paper, or other substances.

The compounds of silver possess the remarkable property of dissolving in hyposulphite of soda, even when insoluble in water and acids, and this property is made use of in photography to fix the images by removing the unaltered chloride, &c. of silver.

55. *Gold.*

Symbol Au (Aurum). Equivalent = 99·6.

This metal is found native, as in the gold fields of California, Australia, and others. It is very widely distributed, but often in quantity too small to pay for its extraction. The sand of the Rhine and of most rivers contains traces of it. It is also found combined with tellurium, and alloyed with silver and palladium. Many kinds of pyrites contain gold enough to pay for the working, and it has also been found in galena.

Gold is distinguished by its yellow colour, bright lustre, and great density. Its specific gravity is 19,500. It is the most malleable of all metals, and also highly ductile. It melts in a white heat.

Gold does not combine directly with oxygen, and is dissolved by no single acid, but only by a mixture of nitric and hydrochloric acids, called aqua regia, or nitro-hydrochloric acid. This forms a chloride from which alkalies precipitate the oxide, which is a teroxide, $Au\,O_3$, as a brownish-yellow powder, which loses its oxygen when exposed to a moderate heat. It has weak acid properties, and is sometimes called auric acid. There is a suboxide of a violet colour, little known.

The terchloride of gold, $Au\,Cl_3$, is by far the most important compound. It is formed, as above stated, by means of aqua regia. It is reduced to the metallic state by protosulphate of iron, by formic acid and formiates, by oxalic acid, and by various metals. With the chlorides of the positive metals terchloride of gold forms crystallizable double chlorides.

The compounds of gold with sulphur are little known. Hydrosulphuric appears to form, in solution of the terchloride, a bisulphuret, which is black.

56. *Platinum.*

Symbol Pt. Equivalent = 98·7.

This metal is also found native, but combined or mixed with five other metals, namely iridium, rhodium, palladium, ruthenium, and osmium, all of which occur in very small quantity in the native platinum which is found in grains. Aqua regia dissolves the whole, except the black scales of an alloy of iridium and osmium, and a few particles of iridium. The solution is mixed with sal-ammoniac, and the bichloride of platinum which has been formed combines with that salt, chloride of ammonium, to form a nearly insoluble double chloride, $Pt\,Cl_2, NH_4\,Cl$, which is deposited as a bright yellow powder. If much iridium be present, the salt is coloured reddish from the presence of the corresponding double chloride of iridium. The washed salt is dried and ignited, when it leaves spongy platinum. By repeating the process the iridium is got rid of in the mother liquid. The spongy metal is made into a paste with water in a wooden mortar, and this paste gradually but powerfully compressed till it assumes a metallic aspect. It is then heated red-hot and hammered gently, and this is repeated till it becomes of full density. It has a grayish-white colour, a high lustre, and a specific gravity of 21,500.

It forms two oxides, a protoxide and a deutoxide, which are feeble bases, and little studied. Its most important compound is the bichloride, $Pt\,Cl_2$. This, with the chlorides of the positive metals, forms crystallizable and permanent double chlorides. Those of potassium and ammonium are nearly insoluble, and the latter, as above stated, yields pure spongy platinum when heated. That of sodium is soluble even in alcohol, and forms fine large crystals. In consequence of this property bichloride of platinum is used to absorb the ammonia formed from the nitrogen of organic compounds, and thus to determine the quantity of that nitrogen.

When the bichloride, which is an orange-coloured soluble salt, is heated to a certain point, it loses half its chlorine, and leaves a protochloride, as a green powder, insoluble in water, but soluble in hydrochloric acid. This chloride also forms double chlorides with the chlorides of the positive metals. With ammonia it gives rise to a remarkable series of bases containing platinum, nitrogen, hydrogen, and in some cases chlorine. These resemble organic bases.

The other metals found along with platinum are extracted from the mother liquid after the precipitation of the platinum by sal-ammoniac, by a very tedious and complex series of operations. Iridium and osmium are also obtained from an alloy of these metals left undissolved by the acid. They all resemble platinum, iridium the most, then rhodium, ruthenium, palladium, and osmium. Their chlorides are the chief compounds, except in the case of osmium, which forms with oxygen a remarkable crystallized and volatile acid, osmic acid, $Os\,O_4$. These chlorides form double chlorides with potassium, ammonium, sodium, &c., analogous to those of platinum. The salts of rhodium are rose-coloured, those of iridium of various colours, those of palladium brown, and those of ruthenium reddish. All these metals are very infusible, and unaltered in the fire, like platinum. But they are so scarce, except palladium, which is malleable, and is used by dentists instead of gold, that they can hardly be applied to useful purposes. Iridium, or rather an alloy of it with a little platinum, as found in the ore, in small grains, is used for the points of gold pens, and from its extreme hardness does not perceptibly wear. Iridium is also the heaviest of metals, its specific gravity being 26,000. We shall not enter into further detail in regard to these very scarce metals.

Having concluded this brief notice of the elementary bodies, and of their chief binary compounds, the reader is now acquainted with the fundamental facts of chemistry. There is, however, an important class of compounds which we have only noticed incidentally, namely the salts, and although we cannot describe them in detail, we may offer some general remarks which will facilitate the study of them.

One division of saline compounds has been described in the place they naturally occupy, namely, those salts called haloid salts, formed of a metal united to such bodies as chlorine, bromine, &c. These, in fact, are true typical salts, for the very substance from which the name of the class is taken, common or sea salt, is one of them, being the chloride of sodium. In one sense, every body having similar properties may be called a salt; every body which is crystalline, more or less soluble, sapid, and neutral. Accordingly at an early period the term salt was extended to such bodies in general, and even after the true nature of common salt was known (for it had long been viewed as a compound of hydrochloric acid and soda) those bodies which really consisted of an acid and a base, both generally oxidized, such as sulphate of soda, nitrate of potash, and the like, were still regarded as salts, and even considered as the only true salts, on the theory that a true salt was a neutral compound of an acid and a base. This theory, in the end, actually excluded common salt from the class of salts; and therefore two kinds of salts were admitted; oxygen salts, of which sulphate of soda, $Na\,O,\ SO_3$, is a type; and haloid salts, of which common salt, $Na\,Cl$, is the

type. We have already shown how, by the progress of chemical discovery, we have been enabled to reduce to one series the two classes of acids, namely, oxygen acids, such as sulphuric acid, HO, SO_3, and hydrogen acids, such as hydrochloric acid, HCl. This is done by regarding the hydrogen in the former as being combined, not first with oxygen to form water, and the water with the dry acid, but as united with a radical, SO_4, differing from chlorine only in being certainly compound. Although this particular radical, SO_4, be not yet known in a separate form, many such compound radicals are known, and play exactly the part of chlorine. Of these cyanogen, $C_2N = Cy$, is the type. On this view, therefore, while hydrochloric acid can only be HCl, sulphuric acid, represented as H, SO_4, or more simply, making $SO_4 = Su$, by HSu, becomes as perfectly analogous to it in formula as it is in properties.

Now, if we adopt this view of acids, or at least of all such acids as cannot exist in an active state without hydrogen, formerly supposed to be present as water, we must apply the same view to the salts of those acids. For when hydrochloric acid acts on a base, such as soda, two phenomena are constantly observed—the formation of a neutral salt and the separation of water. This is perfectly obvious from the equation (M representing any metal), $HCl + MO = MCl + HO$. But when sulphuric acid acts on the same bases the phenomena are absolutely the same; a neutral salt is formed, and water separated. And this we express by the equation, $H, SO_4 + MO = M, SO_4 + HO$.

Here, then, we see the first great principle to be admitted concerning salts. They represent hydrogen acids, in which the hydrogen is replaced by a metal, and therefore acids (that is, hydrogen acids, which includes what used to be called hydrated acids) and salts form in reality but one series, the general formula of which is XR; R being any negative acid radical or salt radical, for the terms are synonymous, and X standing for the positive element, which may be either hydrogen or a metal. So that acids, in this view, are salts of hydrogen, and salts are salts of metals. Hydrogen, indeed, is possibly or even probably the gas of a very volatile metal, whose salts are peculiar in this, that they possess those characters which we call acid. The analogy between neutral salts and acids, nay, even between neutral salts, acids, and bases, or alkalies, did not escape the first scientific chemists, although they knew nothing of the true constitution of any of them. In all works published towards the end of the last century, acids, alkalies, and neutral salts are all included under the head of saline substances. This view, founded on acute observation, was for a time displaced by the limited notion of a salt being a compound of an acid and an alkali, which, as we have seen, actually excluded common salt from the class of salts, as soon as it was shown to contain neither oxygen nor hydrogen, and consequently not to be, as was supposed, a compound of hydrochloric acid with soda. But the progress of science has shown that as oxygen can no longer be called the acidifying principle, since hydrogen is better entitled to the name, so all acids, bases, and salts really belong to one series, that represented by XR. Water may be taken as the type of all such compounds, and while its oxygen may be replaced by chlorine, bromine, iodine, fluorine, sulphur, selenium, cyanogen, the radicals, SO_4 (in sulphuric acid), NO_6 (in nitric acid), &c. &c., its hydrogen may be replaced by any metal, or by such compound radicals as can play the part of metals, as cyanogen and SO_4 play that of chlorine. In organic chemistry there are, as we shall see, many such radicals, of which ethyle, $C_4H_5 = Ae$, is a good example.

Such being the nature of salts in general, it is easy to see how neutral salts are formed when acids and bases act on each other. They were formerly supposed to combine directly, but we now know that if the acid be a hydrogen acid, or a hydrated acid, and the base an oxide, this is not the case, but that water is always formed, as in the general equation, $HR + MO = MR + HO$. We have just stated how this applies to sulphuric acid, HO, SO_3, or rather, H, SO_4. But when anhydrous sulphuric acid acts on an anhydrous base, the reaction is different; no hydrogen being present, no water can be formed, but yet the same neutral salt is formed, as, to take the case of sulphuric acid and soda, both anhydrous, in the equation, $NaO + SO_3 = Na, SO_4$. Here, instead of simply uniting together, the acid and base react on each other; the oxygen of the base is transferred to the acid, producing the radical, SO_4, and with this the metal unites.

The salts of ammonia come into the same category as those of metallic protoxides. For, as has been already explained, in every salt of ammonia, NH_3, with an oxygen acid, there is found, besides the ammonia and anhydrous acid, invariably 1 eq. of water, HO, or rather its elements. The salt, NH_3, SO_3, if it exist at all, is not sulphate of ammonia. That salt contains the elements, NH_3, HO, SO_3, which, on the old view, are arranged as NH_4O, SO_3, sulphate of oxide of ammonium, and on the new as NH_4, SO_4, or, making ammonium, $NH_4 = Am$, it is written Am, SO_4, perfectly corresponding to K, SO_4, sulphate of potash, which it resembles very closely in properties. When ammonia, NH_3, acts on hydrogen acids, such as hydrochloric acid, is was formerly supposed to combine directly with the acid, and the resulting salt, sal-ammoniac or hydrochlorate of ammonia, was written NH_3, HCl. It is now believed that here also ammonium is formed by the hydrogen of the acid combining with the ammonia, and that the compound metal thus formed combines with the residual chlorine, just as potassium would do; so that the result is $NH_3 + HCl = NH_4, Cl = AmCl$, and the salt is now called, accordingly, chloride of ammonium, being perfectly analogous in all respects to chloride of potassium or sodium. In other words, as cyanogen or SO_4 may replace the oxygen of water or the chlorine of sea-salt, so ethyle, $C_4H_5 = Ae$, and ammonium, $NH_4 = Am$, can replace the hydrogen in water and the metal in salt, being, in fact, compound metals.

On the views above explained, neutral salts become exceedingly simple, and the law of their formation very easily remembered, while water, acids, and bases all fall into the same category.

Besides neutral salts, there are acid or supersalts, and alkaline or subsalts. The former, in the case of such acids as sulphuric acid, may be regarded as compounds of the acid with a neutral salt. Thus acid sulphate, or bisulphate of potash is $KO, HO, 2SO_3 = K, SO_4 + H, SO_4 = \left.\begin{matrix}K\\H\end{matrix}\right\} \begin{matrix}SO_4\\SO_4\end{matrix}$. The latter are compounds of the neutral salt with an additional quantity of the base, as, for example, subnitrate or basic nitrate of lead, which is $2PbO, HO, NO_5 = PbO, NO_5 + PbO, HO = Pb, NO_6 + PbO, HO$.

There is, however, another kind of acid salts, namely, those of polybasic acids. Of such acids, phosphoric acid is an excellent type, in two of its three modifications, the bibasic and tribasic phosphoric acids. Polybasic acids, especially bibasic ones, are very frequent in organic chemistry. Of the organic bibasic acids, oxalic acid is the type.

A bibasic acid is one which, to form a neutral salt, requires 2 eqs. of base. Bibasic phosphoric acid is $PO_5, 2HO$, or rather H_2, PO_7, the 2 eqs. of hydrogen being replaceable by metals. The neutral bibasic phosphate of silver is Ag_2, PO_7. But if only 1 eq. of hydrogen be replaced by a metal, we have the acid only half neutralized, or an acid salt, as the acid bibasic phosphate of silver, which would be $\left.\begin{matrix}Ag\\H\end{matrix}\right\} PO_7$, or that of potash, which is $\left.\begin{matrix}K\\H\end{matrix}\right\} PO_7$.

The same is true of tribasic acids, which form three series of salts with the same base, according as 1, 2, or 3 eqs. of

hydrogen are replaced by the metal. Tribasic phosphoric acid is PO_5, 3 $HO = H_3, PO_8$; and it forms with soda, three salts, namely, the acid salt $\left.\begin{matrix}Na\\H_2\end{matrix}\right\}PO_8$, the acid salt $\left.\begin{matrix}Na_2\\H\end{matrix}\right\}PO_8$, and the neutral salt Na_3, PO_8. The two latter are alkaline in reaction on test paper, although acid and neutral in composition; but, in fact, all three, as well as the two salts of the bibasic acid, are, strictly speaking, neutral salts in composition, since they all contain the same number, whether two or three, according to the acid, of basic equivalent, whether metal or hydrogen. Accordingly, all the three salts of soda with the tribasic acid, form, with salts of silver, the same yellow precipitate of neutral tribasic phosphate of silver, Ag_3, PO_8. Oxalic acid is $C_4 O_6$, 2 $HO = H_2, C_4 O_8$, and it forms a neutral oxalate of potash, $K_2, C_4 O_8$; an acid oxalate of potash called binoxalate, $\left.\begin{matrix}K\\H\end{matrix}\right\}C_4 O_8$, and a double acid oxalate of potash, called quadroxalate, $\left.\begin{matrix}K\\H\end{matrix}\right\}C_4 O_8 + H_2, C_4 O_8$.

With regard to salts considered individually, they may be studied either under the head of all the salts of one acid radical with different bases, or all those of one base with different acid radicals. On the former plan they are arranged as sulphates, nitrates, phosphates, chlorides, bromides, &c.; on the other as the salts of potassium, sodium, ammonium, iron, lead, silver, &c. There are conveniences belonging to both systems, but our space will not permit us to enter into either. We can only point out that all the salts of one radical, all the sulphates, or all the chlorides exhibit the characters of that radical. Thus all the soluble sulphates form an insoluble precipitate of sulphate of baryta when mixed with salts of that base. All the chlorides are in like manner precipitated by salts of silver. All the nitrates deflagrate with red-hot charcoal, &c. Nor are we confined to one character; for all the sulphates, for example, when ignited with charcoal, yield sulphurets, and the smell of hydrosulphuric acid is perceived when acids are added to the ignited mass. This is because they all contain sulphur.

Again, all the salts of one metal or base exhibit the chemical characters of that metal. Thus all the salts of sesquioxide of iron give Prussian blue with ferrocyanide of potassium. All the salts of silver give the insoluble chloride on the addition of hydrochloric acid or solution of salt.

Now, as we have in all cases given the characters by which acids and radicals, metals and bases, may be recognised, the chemical characters of any salt may be known by referring to those of its elements. We may merely state here that the most valuable and important salts, most of which have been noticed incidentally under the head of their acids or their bases, are the sulphates, especially those of lime, magnesia, baryta, soda, potash, alumina and potash, iron, zinc, copper, and ammonia; the nitrates of potash, soda, strontia, lead, mercury, and silver; the carbonates of lime, magnesia, potash, soda, ammonia, iron, zinc, lead, &c.; the phosphates of soda, potash, lime, of magnesia and ammonia; the chlorate of potash, the chromates of potash and of lead; and many salts of organic acids not yet described, as oxalates of lime and of ammonia, acetates of potash, soda, alumina, iron, zinc, and lead; and tartrates of potash, potash and soda, and potash and antimony. The haloid salts, such as chloride of sodium, iodide of potassium, fluoride of calcium, &c., have been described in their proper place.

ORGANIC CHEMISTRY.

We must now turn to the chemistry of organized bodies, animal and vegetable, and of the unorganized or structureless products of animal or vegetable life, both of which classes of compounds are called organic.

As formerly explained, the elements of organic bodies are the same as those which constitute the inorganic world, save that the relative proportions are different, and that few comparatively of the elements can enter into the composition of organic compounds. The chief mass of such compounds is formed of only four elements, carbon, hydrogen, nitrogen, and oxygen; frequently of carbon, hydrogen, and oxygen alone; sometimes of carbon and hydrogen only. In every case of an organized structure, however, or of any substance capable of being formed into such a structure or tissue, there are not only the four elements just mentioned, but also sulphur, and several mineral salts in small proportion, but equally essential with the rest. These salts are phosphates, chlorides, alkalies, probably introduced as carbonates, oxide of iron, and frequently iodides and fluorides. Where these saline matters are absent—that is, where the substance, on being burned, leaves no ashes—it is invariably destitute of organized structure, and frequently either crystallized or liquid, both these forms being incompatible with organization.

Organic substances then are characterized by the small number of their elements, and, since they are themselves exceedingly numerous, by the great variety of proportions in which the same elements are united. By far the greater number of organic compounds are only products of organic life, and not themselves organized; and these consist either of the four elements which may be called organic, carbon, hydrogen, nitrogen, and oxygen, or of carbon, hydrogen, and oxygen, without mineral matter or ashes. Such compounds are the vegetable acids, sugar, gum, oils and fats, the vegetable bases, colouring matters, resins, and the like, in plants, and in animals such compounds as fats and oils, bile, urea, animal acids, and bases, &c. To these must be added the innumerable compounds derived from them by various chemical processes. The few organized tissues, and the substances of which these may be formed, are such bodies as bone, muscle, nerve, membranes, woody tissue, albumen, fibrine, caseine, gelatine, chondrine, and the like.

Now, all such organic substances, organized or not, agree in containing a large amount of carbon; and as this is combined with the elements we have named, oxygen, hydrogen, nitrogen, and in some cases sulphur, the action of heat on them, with or without the access of air, is peculiarly characteristic, and enables us at once to recognise organic compounds. Heated in close vessels, they blacken, give off water, oily matter, and combustible gases, and leave behind a black mass, composed of carbon and ashes, if there be ashes present. Heated in the open air, they are oxidized, the whole of their hydrogen being given off as water, their carbon as carbonic acid, their nitrogen as ammonia or as nitrogen gas, while the ashes alone remain. In the first case, which is called the destructive distillation of organic matter, the oxygen present is chiefly taken up by hydrogen to form water, while the carbon enters into new combinations with hydrogen and oxygen, or with hydrogen alone, or with nitrogen; and as all the compounds thus formed are gaseous, the carbon is carried off, as far as the quantity of the other elements admits of, but a large part is always left as charcoal, for want of other elements to combine with it. All organic bodies, therefore, are charred by heating when air is excluded, as in a retort or in the bottom of a tube, and burn when heated with a full supply of air. These characters depend on the nature of the elements they contain, and above all, on the presence of so large a proportion of carbon.

Organic bodies differ from the inorganic in their comparatively complex formulæ. Thus, in inorganic chemistry we constantly meet with such formulæ as those of water, HO, hydrochloric acid HCl, potash KO, sulphuric acid SO_3 or HO, SO_3, and the like. But the simplest organic

compounds are more complex than this. Formic acid is $C_2H_2O_4$, oxalic acid $C_4H_2O_8$, acetic acid $C_4H_4O_4$, and these are by far the simplest organic compounds. Benzoic acid is $C_{14}H_6O_4$, urea is $C_2H_4N_2O_2$, sugar is $C_{12}H_{12}O_{12}$, quinine is $C_{20}H_{12}NO_2$; and while many organic compounds are equally or more complex, some of them, especially those which are capable of forming blood and tissues, contain hundreds of atoms in a single molecule. This peculiar complexity of constitution, while but a small number of elements are employed, is a very marked character of organic compounds, and one consequence of it is, that they are much more easily decomposed by heat or by chemical means than inorganic substances, while the products of their decomposition are singularly varied. In fact, when so many atoms are present, and the elements are capable of uniting two and two or three together, in an endless variety of proportions less complex than the compound acted on, the results may be modified almost *ad infinitum* by altering the circumstances, such as temperature, or the reagents employed, which may be oxygen, or different oxidizing agencies of various energy, or acids, or bases, or chlorine, or any two or more combined, or any of the various modes of deoxidation, or of removing hydrogen, and so on; when such are the conditions, it is easy to see that the results must be infinitely more varied than they can possibly be in the case of inorganic compounds, the composition of which is in general so little complicated. This capability of undergoing numerous decompositions or transformations under the influence of the known chemical agencies is another characteristic feature of organic compounds; and there are causes of change which are almost peculiar to organic substances, such as the action of what are called ferments, and the power we have of replacing one or more atoms of one of the elements of such compounds, generally the hydrogen, by its equivalent of other elements, or even of compound radicals, or groups acting the part of elements. We may say, then, that organic compounds are complex in their constitution, and in consequence peculiarly liable to transformations and decompositions of various kinds—a character which renders them eminently fitted for the functions they have to perform in plants and animals. And while this is true of organic compounds generally, it is especially true, as was formerly hinted, of those which contain nitrogen, from the fact that that element has nearly equal affinities for the three elements which accompany it, and a great tendency also to combine with two or with all three of them in various proportions. Those organic bodies, and they are numerous, which undergo spontaneous transformations, are always compounds containing nitrogen.

Another peculiarity of organic compounds is this, that all their chief elements are either gaseous in themselves, or have a strong tendency to form gaseous or volatile compounds; so that the ultimate result of the transformations of the most complex of them, aided by the atmosphere, is their entire conversion (the ashes alone excepted) into the least complex gaseous forms; and they are sent into the air in those forms, which are, carbonic acid, CO_2; water, HO; ammonia, NH_3; hydrosulphuric acid gas, HS; and sulphuric acid, HO, SO_3. The decay of a dead animal or of a dead tree produces these very substances; and the whole mass of both, excepting the ashes, is dissipated in these forms, chiefly by the action of the atmospheric oxygen, aided by their own tendency to change. In this way, not only is the accumulation of dead organic matter prevented, but its disappearance is, as we shall see, the regular and unfailing source of food to the new generation of plants, and to the animals which feed on them. There are no elements known to us which are capable of undergoing these successive changes, except those which we find in organic matter.

Such are the characters which distinguish organic from inorganic compounds; and it will be seen that, while in both classes the same laws of combination prevail, the peculiarities of the former depend on the peculiar nature of their principal elements.

The number of natural organic compounds is so great, and that of the compounds derived from them artificially is so much greater, that we cannot pretend to describe them all. We can only state such general laws as are deducible from what is known, and indicate the groups or series into which organic substances naturally fall. We shall find that they have a peculiar tendency to form groups of analogous constitution and properties, and that these groups exhibit a repetition, on a larger scale, of what we have already seen among elementary bodies. There are, no doubt, many organic compounds which as yet appear to stand alone; and this renders a satisfactory classification for the present unattainable. But this is entirely due to the imperfection of our knowledge, and the rapid daily progress of organic chemistry is constantly opening up new views, which enable us to include in the known series more and more compounds every day. This progress also demonstrates that the natural groups of organic compounds are formed on the same principles as those of inorganic substances; that the types, so to speak, are the same, while the differences do not affect essential or fundamental points, and the general analogy is unmistakeable.

COMPOUND ORGANIC RADICALS.

Organic chemistry has been defined as the chemistry of compound radicals, as opposed to inorganic chemistry—that of elementary or simple radicals. But since we have come to admit in the latter such compound radicals as SO_4 in sulphuric acid and sulphates, NO_6 in nitric acid and nitrates, and many others, this definition cannot be maintained. We might say, indeed, that organic chemistry was that of such compound radicals as contain carbon. It is probable that all organic compounds contain at least one such radical (except in the case of ammonia and its derivatives, amide and ammonium, if considered organic), and that this is the cause of their complexity.

A compound organic radical is a group which plays the part of an element, and enters as a whole into combination with either elements or other compound radicals. Only a few of the organic radicals admitted by chemists are known in the separate state, but some are known with certainty; and where this is not the case, yet the assumption of the existence of such a radical often simplifies, in an extraordinary degree, the understanding of a whole series of connected substances, and reduces them to a form as easily remembered as in the case of a metal or a negative radical, such as chlorine.

Among organic radicals we find the same diversity of character as among elementary bodies. Some are negative, resembling chlorine, &c., in their relations; others positive, resembling hydrogen or metals; some, again, are more analogous to combustible bodies like carbon and sulphur; and some cannot be referred exactly to any of these categories, but partake of more than one. These differences of negative and positive, however, are, as the reader knows, differences of degree; so that all radicals, compound as well as simple, may be arranged in a series, in which each is positive to the next on one side, and negative to the next on the other. Among the elements this is well known; of the organic radicals, too few are yet known to enable us to establish such a series, save in a very fragmentary manner.

Of strongly negative organic radicals, analogous to chlorine, cyanogen is the type, and the analogy is here truly surprising. Thus we have—

With Chlorine, Cl.	*With Cyanogen*, $C_2N = Cy$.
Hydrochloric acid, H Cl	Hydrocyanic acid, H Cy
Hypochlorous acid, Cl O	Cyanic acid, Cy O
Chloride of potassium, K Cl	Cyanide of potassium, K Cy
Bichloride of mercury, Hg Cl_2	Bicyanide of mercury, Hg Cy_2

There are other negative radicals, chiefly derived from cyanogen, such as ferrocyanogen, $C_6 N_3 Fe = Cy_3 Fe = Cfy$, sulphocyanogen, $C_2 N S_2 = Cy S_2 = Csy$, and various others, which exhibit a general resemblance to chlorine in their relations, forming acids with hydrogen and salts with metals.

Of such positive radicals as are analogous to hydrogen and metals, and can, indeed, replace them, the simplest and the type is methyle, $C_2 H_3 = Me$. Let us compare it with potassium. We have—

With Potassium, K.	*With Methyle*, $C_2 H_3 = Me$.
Protoxide, basic, KO	Protoxide, basic, Me O
Hydrated protoxide, KO, HO	Hydrated protoxide, Me O, HO
Chloride, K Cl	Chloride, Me Cl
Iodide, KI	Iodide, Me I
Sulphuret, KS	Sulphuret, Me S
Cyanide, K Cy	Cyanide, Me Cy
Nitrute, K, NO_6	Nitrate, Me, NO_6
Carbonate, KO, CO_2	Carbonate, Me O, CO_2
Acetate, KO, $C_4 H_3 O_3$	Acetate, Me O, $C_4 H_3 O_3$

This list might be extended to a great length, and the analogy would hold good. It is easy to see how much the assumption of the radical methyle simplifies its compounds, the formulæ of which, written at full length, no one could be expected to remember, many of them being very like each other. Thus the carbonate is $C_3 H_3 O_3$; the cyanide, $C_4 H_3 N$; the hydrated oxide, $C_2 H_4 O_2$; and the acetate, $C_6 H_6 O_4$.

There are very many radicals of this class, and all more complex than methyle, but all equally simple when considered as radicals, each having its own symbol. Thus, we have ethyle, $C_4 H_5 = Ae$; amyle, $C_{10} H_{11} = Ayl$; cetyle, $C_{32} H_{33} = Ct$; phenyle, $C_{12} H_5 = Ph$; and many others.

Of the radicals analogous to sulphur or carbon, benzoyle is a type. Its formula is $C_{14} H_5 O_2$; its symbol Bz; and we have it, as well as sulphur, in combination with—

	Sulphur.	Benzoyle.
Hydrogen............	HS	H Bz
Oxygen............	SO_3, HO	Bz O, HO
Chlorine	S Cl	Bz Cl

The analogy is not so close here as in the other cases, but the principle is the same. There are a good many radicals of this type, all forming with hydrogen volatile oils, with oxygen volatile acids. Acetyle, $C_4 H_3$, or rather formyle, $C_2 H$, is the type of another allied group of radicals, which form with hydrogen volatile oily products, and with oxygen volatile acids of an oily character.

Such are the general characters of some of the best known groups of organic radicals, and it is precisely the compounds connected with these which are best known, and the study of which is most simplified by the admission of these radicals.

ISOMERISM IN ORGANIC COMPOUNDS.

Another remarkable feature in organic compounds is the frequent occurrence of isomerism or polymerism. This is the natural result of the large number of atoms generally present, which of course admits of a great variety in their arrangement, giving rise to isomeric compounds; while the absolute number also varies, being double, or treble, or manifold in one compound of what it is in another, thus producing polymeric compounds. It is obvious that in either case the transformation of one compound into the other must be comparatively easy, since nothing is necessary to be added nor taken away.

As examples of isomerism, that is, of bodies with the same proportion of elements and the same absolute quantity, which makes the atomic weight or equivalent the same, we may mention cyanate of ammonia (of oxide of ammonium), and urea. The former is $Am O, Cy O = NH_4 O, C_2 NO$. In the latter the rational formula is not known with certainty, but the empirical formula is $C_2 H_4 N_2 O_2$, which, it will be seen, is the same, absolutely and relatively, as the other. Again, acetate of oxide of ethyle is $Ae O, Ae O_3 = C_4 H_5 O, C_4 H_3 O_3 = C_8 H_8 O_4$, while butyric acid is $C_8 H_7 O_3, HO = C_8 H_8 O_4$. These two substances are totally different, and we are able to express the difference in the rational formulæ, which shows the first to be a neutral salt of oxide of ethyle, the second a hydrated acid. A still more striking case of isomerism is that of the following substances, in several of which the rational formula is unknown, but all of which have the same atomic weight, and entirely different properties :—

Substance.	Empirical Formula.	Rational Formula.
Alanine; a base	$C_6 H_7 NO_4$	$C_6 H_6 NO_3$, HO ?
Sarcosine; a base	$C_6 H_7 NO_4$	$C_6 H_6 NO_3$, HO ?
Carbamate of oxide of ethyle...	$C_6 H_7 NO_4$	$C_4 H_5 O, C_2 H_2 NO_3$
Hyponitrite of oxide of propyle	$C_6 H_7 NO_4$	$C_6 H_7 O, NO_3$

Here we have at all events three totally distinct rational formulæ, and in regard to the two first substances it is not that they have the same rational formula, but that we do not yet know the difference, which, as both seem to be hydrated bases but of distinct properties, must of course be in the arrangement of the anhydrous base $C_6 H_6 NO_3$. There must be a difference, and we might even from analogy conjecture several modes of explaining the difference of properties, but nothing is certainly known of it. It is quite probable that several more substances having the same composition and atomic weight may still be added to this list. These examples of strict isomerism will suffice. As to polymerism, we have an example of it, connected with the four substances just mentioned; for lactamide, a body quite different from all four, has the empirical formula $C_{12} H_{14} N_2 O_8$, exactly double of theirs. Its rational formula is probably $C_{12} H_{10} O_8, 2 NH_2$, which represents the neutral amide of lactic acid, a bibasic acid. We have also an example of polymerism, connected with acetic ether and butyric acid, the empirical formula of which is $C_8 H_8 O_4$. That of aldehyde is $C_4 H_4 O_2$ or exactly one-half, while its rational formula is $C_4 H_3 O, HO$, that is, hydrated protoxide of acetyle. Besides this, we have metaldehyde and elaldehyde, polymeric with aldehyde, the precise equivalent of which is doubtful. There are also the three acids, formed of cyanogen and oxygen, namely:—

Cyanic acid	Cy O, HO	=	$C_2 NO$, HO
Fulminic acid	$Cy_2 O_2$, 2 HO	=	$C_4 N_2 O_2$, 2 HO
Cyanuric acid...........	$Cy_3 O_3$, 3 HO	=	$C_6 N_3 O_6$, 3 HO

Many other examples might be given, both of isomerism and of polymerism; but those already given are sufficient to illustrate the principle. There is, indeed, a remarkable class of compounds, namely, the volatile bases, homologous with ammonia, and in which the hydrogen of that substance is partially or entirely replaced by radicals of the ethyle series, which exhibit isomerism carried to an extraordinary point, as will be more particularly explained under the head of these bases. Suffice it here to say, that we may easily form two volatile bases similar in properties, but quite distinct, of the formula $C_4 H_7 N$; three such bases of the formula $C_6 H_9 N$; four of the formula $C_8 H_{11} N$; six of $C_{10} H_{13} N$; and so on, the number regularly increasing with the amount of carbon, so that with 20 eqs. of carbon we may have 16 volatile bases, all of the same empirical formula $C_{20} H_{23} N$, and yet all distinct, and each having its own well ascertained rational formula. Nor does this stop here, for with every 2 eqs. of carbon by which the formula is augmented, the number of possible isomeric (not polymeric) volatile bases is increased by two. This will give the reader some notion of the extraordinary fertility of organic chemistry, and of the important part performed by isomerism in the transformation of organic compounds. It is but the other day that these volatile bases were discovered, and already some dozens of them are known.

The examples of isomeric and polymeric transformation are very numerous, and there can be no doubt that this is a principle constantly in action in living organisms, animal or vegetable. The artificial formation of urea is a striking instance. The cyanate of oxide of ammonium, which we

have just seen to be isomeric with urea, spontaneously changes into that substance when its solution is left to itself, and rapidly if warmed. Urea, when heated, is transformed or resolved into ammonia, and hydrated cyanuric acid, polymeric with cyanic acid. That is to say, 3 eqs. of urea yield three of ammonia and 1 of cyanuric acid, $3\ (C_2 H_4 N_2 O_2) = 3\ NH_3 + Cy_3 O_3,\ 3\ HO$. Again, this very cyanuric acid, when heated, is resolved into 3 eqs. of cyanic acid. $Cy_3 O_3,\ 3\ HO = 3\ (Cy O, HO)$. Cyanic acid, left to itself, is transformed into cyamelide, a body polymeric with it, possibly having twice its equivalent, $2\ (Cy\ O, HO) = C_4 H_2 N_2 O_4$. Cyamelide, when heated, is resolved, like cyanuric acid, into cyanic acid again, $C_4 H_2 N_2 O_4 = 2(Cy\ O, HO)$. If we now add ammonia, we obtain cyanate of oxide of ammonium, and this can be made again to pass through the whole series of metamorphoses just mentioned. Hydrobenzamide, by boiling with potash, is transformed into the base amarine, isomeric or perhaps polymeric with it. Furfuramide, in the same way, is transformed into the base furfurine, which has exactly double its equivalent. Every case of fermentation, strictly so called, is one of isomeric or polymeric transmutation; not, however, generally into one, but into two or more compounds. Dry grape sugar $C_{12} H_{12} O_{12}$ yields, in the vinous fermentation 2 eqs. of alcohol and 4 of carbonic acid, $C_{12} H_{12} O_{12} = 2\ (C_4 H_6 O_2) + 4\ CO_2$. The same substance, in the lactic fermentation, yields the isomeric lactic acid, $C_{12} H_{12} G_{12} = C_{12} H_{10} O_{10},\ 2\ HO$. Lactic acid, in the butyric fermentation, is resolved into butyric acid, carbonic acid, and hydrogen, $C_{12} H_{10} O_{10},\ 2\ HO = C_8 H_7 O_3, HO + 4\ CO_2 + H_4$. It is easy to see how very important a principle this is, in reference to the vital changes which constitute organic life, animal or vegetable. It is in some such way that the food of plants and animals is assimilated, and becomes converted into those substances of which the animal and vegetable frames are composed. It is more particularly in the animal body, however, that isomeric transformations prevail, because the food of animals is complex, and therefore liable to transformation, and adapted to undergo it. We can even, in some measure, imitate artificially the change by which some parts of the food of animals are dissolved into blood. For we can so treat fibrine as to obtain from it a solution of albumen, much resembling the serum of blood; and albumen is either isomeric with fibrine or very nearly so.

ORGANIC TYPES. SUBSTITUTION.

We have seen that great advantage is gained by admitting the existence of organic compound radicals. There is, however, another kind of organic group, which has not the properties of radicals. These are named types, the meaning of which is, that the atoms are grouped together in a certain mode, on which the properties of the compound so entirely depend, that, provided this grouping or arrangement be retained, great changes may be made in regard to the individual elements, without changing the general character of the compound. This leads us to the very remarkable and important law of substitution, which has become so fertile in discoveries of late years. Some writers have imagined that the notion of types was incompatible with that of radicals, but this is not the case. Every radical, nay, every compound of a radical, may also be a type, and we shall find that both ideas are useful in enabling us to classify our knowledge.

The fundamental idea of a type may be found in inorganic chemistry. Hydrochloric acid, $H\,Cl$, is a type, and so is common salt, $Na\,Cl$. All compounds, which, like hydrochloric acid, consist of 1 eq. hydrogen and 1 eq. of a powerful negative radical, are acids. All those which consist of 1 eq. of metal and 1 eq. of negative radical, are salts. We can substitute for the chlorine in either, bromine, iodine, cyanogen, or sulphur, and the compound will still have the original character of an acid or a salt. And in the case of salt, we may substitute for the sodium, potassium, ammonium, barium, iron, lead, silver, &c., and still the result is a salt. In fact, every compound is, or represents, a type, and every chemical change is a substitution. But in inorganic chemistry, the only substitutions which do not destroy the type are those of like for like, of chlorine for iodine, &c., or of one metal for another. It cannot well be otherwise, from the simplicity of inorganic formulæ.

But in organic chemistry, where the formulæ, and consequently the molecules, are so much more complex, the type acquires a new significance. The elements of all organic compounds being the same, and often in the same amount and proportion, the *arrangement* or relative position of the atoms comes to be a matter of the utmost importance, as fixing the character of the group, that is, of the type. A certain mode of arrangement gives acid properties; another, the properties of a base; a third, those of an oil; a fourth, those of an ether, and so on. And so powerful is the influence of arrangement in these complex molecules, that substitution is no longer confined to replacing like by like, but extends to the replacement of an element by its equivalent of another, not only not analogous to it, but actually opposite to it.

Naphthaline is $C_{20} H_8$. The character of the type is, that it is volatile and combustible. Now, we may remove 1 eq. of hydrogen, and replace it, not by anything analogous to hydrogen, but by 1 eq. of chlorine, forming the body $C_{20} \left.\begin{matrix} H_7 \\ Cl \end{matrix}\right\}$; chlonaphtase, which has the same general characters. We may go on replacing the hydrogen, atom by atom, by chlorine, and yet the type will remain unaltered. That is, the properties of naphthaline depend chiefly on the way in which the atoms are grouped, and, provided the grouping be unchanged, it does not appear to signify much whether the 8 atoms attached to the 20 of carbon be all hydrogen, or partly hydrogen and partly chlorine. In like manner, bromine may be substituted for the hydrogen, and yet we know that, in general, chlorine and bromine are strongly opposed to hydrogen, being negative, while it is positive. Here, then, we have negative atoms playing the part of positive ones, and this is the peculiar feature of that kind of substitution in organic compounds which we are now considering. And since the negative character of such bodies as chlorine and bromine is thus, as it were, sunk, nay, changed almost to its opposite, it is evident that in naphthaline the nature of the compound molecule must depend far more on the arrangement or grouping, than on the original nature of the atoms it contains. Even the last atom of hydrogen in naphthaline may be thus replaced by chlorine, yielding the body $C_{20} Cl_8$, which has still the general characters of the type. The peculiarity of this form of substitution (for we must remember that almost all chemical changes consist in substitution of one element for another, as when the oxide of a metal, MO, is converted into the chloride, $M\,Cl$, or the sulphuret, $M\,S$, or the cyanide, $M\,Cy$, or the sulphate, M_4, SO, &c. &c., where chlorine, sulphur, cyanogen, and $S\,O_4$, are successively substituted for oxygen) is still better seen in the action of nitric acid or naphthaline. The first effect is that 1 eq. of hydrogen is oxidized into water; but the oxygen being taken from nitric acid, NO_5, leaves nitrous acid, NO_4, and this complex atom at once takes the place of the hydrogen removed, forming the compound $C_{20} \left.\begin{matrix} H_7 \\ NO_4 \end{matrix}\right\}$, which has still the typical characters, although the place of 1 eq. of hydrogen is now occupied by a compound, containing 4 eqs. of oxygen; the body of all others most opposite to hydrogen. And this is so far from being a solitary case, that a large proportion of organic compounds, whether acid, basic, or neutral, form analogous compounds, in which hydrogen is replaced by the same number of atoms of nitrous acid, of chlorine, and of bromine, the general character of the compound remaining the same.

Chemistry. Many examples might be given. Acetic acid, $C_4 H_3 O_3, HO$, acted on by chlorine, yields chloracetic acid $C_4 Cl_3 O_3, HO$. Aniline, a base, $Cy_2 H_7 N$, acted on by bromine, yields the base bromaniline, $C_{12} \left.\begin{matrix} H_6 \\ Br \end{matrix}\right\} N$. The neutral oil, benzole, $C_{12} H_6$, yields, with nitric acid, the oil nitrobenzole, $C_{12} \left.\begin{matrix} H_5 \\ NO_4 \end{matrix}\right\}$.

It is easy to see that in this way a very large number of new compounds may be obtained, and, in fact, such are every day discovered, the experimenter being guided by the laws we have explained. It must be noticed, however, that although the type, generally speaking, is not altered by such substitutions, as we have just seen that the substitution-products from an acid, a base, and a neutral oil, are acid, basic, and oily and neutral, yet the negative energy of the elements substituted for hydrogen is not altogether lost or sunk. For, although we have from aniline, a base, basic substitution products, such as chloraniline, bromaniline, and nitraniline, in all of which 1 eq. of hydrogen is replaced successively by 1 eq. of chlorine, bromine, and nitrous acid, yet when 2 eqs. of hydrogen are thus replaced, the basic properties are much weakened, and when 3 eqs. have been replaced, as in trichloraniline and tribromaniline, these properties are gone, and the compound is neutral. But the very fact that, in this form, 3 eqs. of chlorine, one of which neutralizes the most basic metals, are just sufficient to destroy the basic character of 1 eq. of a feeble base, proves how much the negative character of chlorine, bromine, or nitrous acid is affected by the peculiar position they are made to occupy in the compound molecule, which only allows their negative character to appear to a small extent, when their quantity reaches a certain point.

Such are the general facts concerning types, and the peculiar form of substitution we have endeavoured to explain, by which the type is not materially changed, although hydrogen be replaced by its opposites. These facts are so far from being inconsistent with the existence of compound radicals, that these radicals are themselves, as types, equally capable of this form of substitution with any other compounds. Indeed, in the case of aniline, which is itself a substitution product of another kind, where hydrogen is replaced, not by its opposites, but by its homologues, as we shall presently explain, it is the radical phenyle, $C_{12} H_5$, contained in it, that undergoes the substitution of chlorine, bromine, and nitrous acid for hydrogen.

This leads us to consider that other form of substitution, also peculiar to organic compounds, to which we have just alluded, and to its results, namely, the formation of what are called homologous series, involving principles which, in reference to the classification and understanding of organic compounds, and to their artificial formation, are of far greater practical value than any we have yet expounded. Indeed, we can now see that the progress of science must inevitably reduce the whole of organic chemistry, in which, we must remember, only the same three or four elements are perpetually met with, to a collection of homologous series, in which every compound will have its natural place, indicative at once of its origin, its immediate derivation, and its properties both physical and chemical. This is so much the case, that the student, if he have a clear conception of the nature and relations of the series we call homologous, will have a far better idea of organic chemistry than he could have without this, even if we had space to describe the innumerable organic compounds, which, without this guiding principle, would form, as they have long done, a perfect chaos of isolated facts, which no memory could retain, and to which it would be impossible to give a rational or connected form. For this reason, we shall give a full explanation of this part of the subject, referring the reader to larger works for the voluminous details concerning individual compounds which are altogether inconsistent with our space.

Although we cannot yet include nearly all organic compounds in the series we are about to describe, yet a large number of the more important may be thus included, and thus a catalogue of the known homologous series will form the skeleton, as it were, or groundwork of an arrangement, in which all the parts may be seen to be mutually related. Those substances which do not themselves naturally fall into any of the series will be mentioned as groups, according to their natural affinities, and it will be found that they are in most cases related to the series of which we speak, through some of the products of their decomposition or transformation. Chemistry.

Lastly, after giving a brief account of those substances which cannot yet be included in the homologous series, we shall explain the changes which occur in living organisms, so far as these are known.

HOMOLOGOUS SERIES.

1. These series have gradually, and of late rapidly, developed themselves from the researches of modern chemists. They arise from a kind of substitution, the commonest of all in organic chemistry, in which hydrogen is replaced by certain compound radicals, which, being themselves homologous, of course give rise to homologous series, when substituted for hydrogen in various compounds. The origin of these homologous series of radicals themselves is more obscure; but, whatever that origin may be, these radicals are so related to each other as to constitute what may be called the chief or fundamental homologous series. Of these, more than one are known, but we shall select the best known and most important, which is that of the methylic or ethylic radicals, so called because methyle and ethyle are the two first radicals of the series. Let us consider these two. Methyle is $C_2 H_3$; ethyle is $C_4 H_5$; and they are, in all respects, closely analogous to one another, and, as has been already stated, to hydrogen and metals. Now what is the difference between them? $C_4 H_5 - C_2 H_3 = C_2 H_2$. Consequently the difference is $C_2 H_2$ or $2\,CH$. So that, by adding $C_2 H_2$ to the formula of methyle, we obtain that of ethyle. To ascertain the true starting point, let us, after subtracting $C_2 H_2$ from ethyle, which leaves $C_2 H_3$ or methyle, subtract the same amount, $C_2 H_2$, from methyle itself, $C_2 H_3 - C_2 H_2 = H$. Therefore hydrogen is the origin or point of departure of this series of radicals, and we have already seen that they are analogous to hydrogen. On the other hand, let us add to the formula of ethyle, once more $C_2 H_2$, and we have $C_4 H_5 + C_2 H_2 = C_6 H_7$, which is the formula of propyle. Another addition of $C_2 H_2$ to propyle gives $C_8 H_9$, which is butyle, and again the addition of $C_2 H_2$ to butyle gives $C_{10} H_{11}$ = amyle, and so on. Such is the nature of this first or fundamental homologous series, and all other homologous series yet known are formed on the same principle of the addition of $C_2 H_2$, neither less nor more, at each step, the starting point alone being different. There is every reason to believe that this first series extends from methyle (or from hydrogen), $C_2 H_3$ to melissyle $C_{60} H_{61}$, although only a few of the radicals, members of this series, are yet known in a separate form.

The first thing to be noticed is, that all the members of the series, being derived from H by the addition of $C_2 H_2$ in successive steps, contain, and must contain, invariably 1 eq. of hydrogen more than of carbon. Secondly, for the same reason, the number of equivalents of carbon is in all an even number, or divisible by 2, while that of the equivalents of hydrogen is odd. These facts are expressed by giving to the series the general formula, $C_n H_{n+1}$, in which n signifies 2, or a multiple of 2 by a whole number. The general formula may also be written $C_{2n} H_{(2n)+1}$. But the former is the simpler mode. The formula $C_n H_{n+1}$ includes all the radicals of this, the methylic or ethylic series. In this, as in all similar homologous series, the compounds

lowest in the scale, that is, with least carbon and hydrogen, are the least dense, the most volatile, and have the strongest affinities; and these properties vary in proportion to the amount of $C_2 H_2$ added, according to a regular law. The density of the vapour or gas increases, and the boiling point rises with perfect regularity, as we rise on the scale. Methyle and ethyle are gases like hydrogen, at ordinary temperatures; but while methyle requires 20 atmospheres to liquefy it, ethyle is condensed by 2 atmospheres, and the condensed liquid boils under the ordinary pressure at 23° or 9° below the freezing point. Propyle and butyle are oily liquids, the latter boiling at 226°, and amyle is an oily liquid boiling at 311°. Higher in the scale, the radicals are solid, but fusible and volatile; and the higher we go, the higher are the melting and boiling points. This at least is found to be the case in all other homologous series, and is no doubt true in this, although as yet all the radicals high in the scale are not known in the separate state.

2. Such is the first or fundamental homologous series of radicals, homologous with, and analogous to, hydrogen. Now these radicals, in the second aud more common form of substitution seen in organic compounds, are substituted for hydrogen, atom for atom, in various compounds, and thus give origin to as many homologous series as there are different compounds in which hydrogen can be replaced by these radicals. Hydrogen, H, is the starting point of the radicals; and water, H O, is the starting point of their protoxides, so that we have—

Hydrogen	H	Water	HO
Methyle	$C_2 H_3$	Oxide of methyle	$C_2 H_3 O$
Ethyle	$C_4 H_5$	Oxide of ethyle	$C_4 H_5 O$
Propyle	$C_6 H_7$	Oxide of propyle	$C_6 H_7 O$
Butyle	$C_8 H_9$	Oxide of butyle	$C_8 H_9 O$
Amyle	$C_{10} H_{11}$	Oxide of amyle	$C_{10} H_{11} O$

and so on, the two series running absolutely parallel. The five protoxides just named are all known, as well as a good many higher in the scale. They are in fact what are called the ethers, oxide of ethyle being common ether. Oxide of methyle or methylic ether is a gas at ordinary temperatures, and the others named are liquids less volatile than ether, while higher in the scale they are solids, as oxide of cetyle, $C_{32} H_{33} O$, which is a crystalline solid, like fat or wax. The general formula of this series is $C_n H_{n+1} O$.

3. The third homologous series is that of the hydrated protoxides of the radicals, or the alcohols; of which the starting point may be said to be 2 eqs. of water H O, H O, which we may suppose to exist, since water can play the part both of acid and base, both negative and positive, and may possibly form double molecules of hydrate of water. At all events we have only to add $C_2 H_2$ to the first equivalent of water, in successive quantities, to obtain the series of the alcohols, which are—that is, the first 5 of them—

Water	HO, HO	
Hydrated oxide of methyle	$C_2 H_3 O$, HO	Methylic alcohol.
... ... ethyle	$C_4 H_5 O$, HO	Ethylic or common do.
... ... propyle	$C_6 H_7 O$, HO	Propylic alcohol.
... ... butyle	$C_8 H_9 O$, HO	Butylic alcohol.
... ... amyle	$C_{10} H_{11} O$, HO	Amylic alcohol.

The whole of these alcohols are formed in the peculiar fermentation of sugar, called the vinous or alcoholic fermentation, and all but the first can only be produced in this way, so far as is yet known. When sugar dissolved is placed in contact with yeast, fermentation ensues, and at a certain temperature, if the sugar be pure, only ethylic alcohol and carbonic acid are produced. Dry grape sugar is the substance which ferments. Its formula is $C_{12} H_{12} O_{12}$, and in fermentation, $C_{12} H_{12} O_{12}$ yield 4 CO_2 and 2 ($C_4 H_6 O_2$). But when impurities are present, other analogous fermentations, though to a less extent, accompany this one; and in the fermentation of the juice of the grape, but especially of the expressed residue or mark of the grape, and also in that of infusion of grain or of malt, the four other alcohols here named, and one or two others next above them in the scale, are formed. We do not know exactly what are the products of the fermentations which produce them, but they must differ from those of the vinous fermentation. Thus, 3 eqs. of sugar $C_{36} H_{36} O_{36}$ may yield 4 eqs. of propylic alcohol 4 ($C_6 H_8 O_2$), 4 eqs. of water, 4 H O, and 12 of carbonic acid, 12 $C O_2$. Again, 5 eqs. of sugar may yield 4 of amylic alcohol, 12 of water, and 20 of carbonic acid. But the changes may be more complex. All that we know is, that in some circumstances not yet fully investigated, 5 or 6 different alcohols are formed from sugar. The amylic alcohol was discovered in the alcohol from potatoes and grain a good many years ago, and since then in that from the grape. In the latter, the methylic, propylic, butylic, and caproic alcohols have very recently been detected. Methylic alcohol is obtained, however, chiefly from the distillation of wood, and is often called pyroxilic spirit.

The propylic and butylic alcohols are perfectly analogous to the rest, and intermediate in properties between common alcohol and amylic alcohol, or oil of potato spirit, which has long been known. This series exemplifies admirably the nature of a homologous series. The physical properties of the alcohols are graduated in exact proportion to the increased amount of carbon and hydrogen. Thus, the boiling point rises about 34° for each step or addition of $C_2 H_2$; so that knowing the boiling point of one alcohol, we can calculate that of all the rest. This was done with respect to the two newly discovered alcohols before they were obtained, and the result agreed perfectly with the calculation. A good many alcohols are known higher in the scale. Spermaceti yields one of them, cetylic alcohol $C_{32} H_{33} O$, HO, and two others have been obtained from wax, namely cerotic or ceric alcohol $C_{54} H_{55} O$, HO, and melissic alcohol $C_{60} H_{61} O$, HO. These three are crystalline, fusible, volatile solids, but have a high boiling point. General formula $C_n H_{n+1}$, O, HO.

It is unnecessary to repeat in each case the statement, which holds good in all, that the physical properties and chemical affinities, in a homologous series, vary with the amount of carbon and hydrogen; the density and boiling point rising and the affinity diminishing as the carbon and hydrogen increase.

4. The fourth series is that of the hydurets of the radicals of the first series, or positive radicals. The general formula is $C_n H_{n+1}$, $H = C_n H_{n+2}$. The first is $C_2 H_3$, H or $C_2 H_4$, hyduret of methyle. This is marsh gas, sometimes written $C H_2$. But $C H_2$ is polymeric only with the true hyduret. The next is hyduret of ethyle, $C_4 H_5$, $H = C_4 H_6$. This series consists of gases, liquids, and solids, and it is believed that some kinds of naphtha, and some kinds of paraffine, belong to it. Naphtha may be $C_{10} H_{12}$, $C_{16} H_{18}$, $C_{20} H_{22}$, and the like, and paraffine may be in some cases, $C_{54} H_{56}$ and $C_{60} H_{62}$. At all events wax yields paraffine, and the substances in wax contain, as we have seen, C_{84} and C_{60}. Marsh gas, $C_4 H_6$, or perhaps $C_2 H_4$, or a mixture of both, is pro duced by the decay of dead vegetable matter at the bottom of stagnant water; also in coal mines. It is formed artificially in various processes.

5, 6, 7, 8. It will be seen that these four series are closely related together, the first containing the positive radicals, while the others contain compounds of those radicals. But these radicals form many compounds, and each compound of any one radical, as methyle or ethyle, indicates another homologous series. We have seen the oxide, the hydrated oxide, and the hyduret, each belonging to such a series. Now, the chloride of methyle is one of a fifth series, the general formula of which is $C_n H_{n+1}$, Cl. The iodide belongs to a sixth, of the general formula $C_n H_{n+1}$, I; the bromide to a seventh; formula $C_n H_{n+1}$, Br. All these, at least in the lower part of the scale, are volatile ethereal liquids, and become no doubt solid higher up. These series are exactly parallel to those already mentioned. An eighth series consists of the cyanides, which are remarkable as con-

taining two compound radicals, but otherwise are quite analogous to the rest. These cyanides are interesting from their being either identical or isomeric with the compounds of another series, the nitryles, connected with a second series of radicals, the negative radicals, to be presently mentioned. The cyanides are also interesting, since from them it is possible to reproduce the corresponding alcohols; and in this way we may be able to obtain certain alcohols which could not otherwise be procured.

9, 10. A ninth homologous series is that of the sulphurets of the positive radicals, which, in the lower part of the scale, are ethereal liquids, with an insupportable garlic odour; general formula $C_n H_{n+1}$, S. A tenth series consists of compounds of the sulphurets with hydrosulphuric acid, of the general formula $C_n H_{n+1}, S + HS$. Of these the types are methylo-mercaptan and ethylo-mercaptan, or simply mercaptan, so called from its strong action on oxide of mercury. These two compounds are $C_2 H_3 S$, H S and $C_4 H_5 S$, H S, while the corresponding sulphurets are $C_2 H_3 S$ and $C_4 H_5 S$. The mercaptans have also a strong and offensive garlic odour. It will be seen that the sulphurets are the oxides or ethers in which sulphur has taken the place of oxygen, and the mercaptans are the hydrated oxides or alcohols, in which the same substitution has taken place; for we have—

Ethers.	Sulphurets.	Alcohols.	Mercaptans.
$C_2 H_3 O$	$C_2 H_3 S$	$C_2 H_3 O$, HO	$C_2 H_3 S$, HS
$C_4 H_5 O$	$C_4 H_5 S$	$C_4 H_5 O$, HO	$C_4 H_5 S$, HS
$C_6 H_7 O$	$C_6 H_7 S$ &c. &c.	$C_6 H_7 O$, HO	$C_6 H_7 S$, HS, &c.

The two series might be extended as far as any of the others.

11. We now come to another group of homologous series, still containing the same radicals, namely the salts of their oxides, or compounds of the oxides with oxygen acids, or, as they are called, the compound ethers. The ethers are capable of uniting with almost all acids, such as sulphuric, nitric, hyponitrous, carbonic, oxalic, acetic, benzoic, and in fact all organic acids. It is evident that the compounds of each acid with the ethers form a homologous series. We shall merely give as an example of the neutral compound ethers, an eleventh series, the carbonates of the oxides of the second series. Their general formula is $C_n H_{n+1}, O, CO_2 = C_{n+1} H_{n+1} O_3$. Those of methyle and ethyle are volatile ethereal liquids, as are indeed the whole class of compound ethers when low in the scale.

12, 13, 14. A twelfth series is that of the acid sulphates of the oxides of the second series. General formula $C_n H_{n+1}$, O, HO, 2 SO_3. These are formed when the alcohols are acted on by excess of sulphuric acid. They are strongly acid, and, when neutralized by fixed bases, form what may be considered either as double salts, or salts of acids containing the ethers along with sulphuric acid. The two first of these acid sulphates are $C_2 H_3 O$, HO, 2 SO_3, called sulphomethylic acid, or double sulphate of water and oxide of methyle; and $C_4 H_5 O$, HO, 2 SO_3, sulphoethylic—or sulphovinic acid, or double sulphate of water and oxide of ethyle. The rest of the series are perfectly analogous to these. When these two, or any of the others are neutralized with potash, which replaces the water, we obtain the sulphomethylate and sulphoethylate of potash, or double sulphates of potash and oxide of methyle or ethyle, which, in fact, belong to a thirteenth homologous series, since every base forms a new series with these acids. The two acids, with their potash and lime salts, may be thus compared:—

Acids.	Potash Salts.	Lime Salts.
$C_2 H_3 O$, HO, 2 SO_3	$C_2 H_3 O$, KO, 2 SO_3	$C_2 H_3 O$, CaO, 2 SO_3
$C_4 H_5 O$, HO, 2 SO_3	$C_4 H_5 O$, KO, 2 SO_3	$C_4 H_5 O$, CaO, 2 SO_3

The lime salts, of course, form a fourteenth series, and here, as in the case of the neutral compound ethers, there is no limit to the number of series, but that of the acids and bases capable of uniting with the oxides of series 2, and the acids of series 12.

15. The next, or fifteenth homologous series that we shall specify, is not only in itself a very remarkable one, but at the same time the source of an infinite number of additional series. It still contains the same positive radicals which have been present in all the series hitherto named. In this one they are combined with amide, NH_2, and the result is, a series of volatile bases formerly alluded to, homologous with ammonia, which is their starting point, as hydrogen is of the radicals; (for ammonia is amide + hydrogen). They are in the highest degree analogous to ammonia, which is the true type of the volatile organic bases. Their general formula is $C_n H_{n+1}$, NH_2, and therefore they contain no oxygen. The formula may also be written $C_n H_{n+3}$, N, which makes it easy to remember, that the hydrogen in all of them exceeds the carbon by 3 eqs., and that there is 1 eq. of nitrogen, and no oxygen. The following are a few of those in the lower part of the scale. We have added a third column to show the analogy with ammonia more clearly, in which the radicals, as well as the amide, are represented by their abbreviated symbols:—

Ammonia,	$H_3 N$	=	NH_2, H	=	Ad H
Methylamine,	$C_2 H_5 N$	=	NH_2, $C_2 H_3$	=	Ad Me
Ethylamine,	$C_4 H_7 N$	=	NH_2, $C_4 H_5$	=	Ad Ae
Propylamine,	$C_6 H_9 N$	=	NH_2, $C_6 H_7$	=	Ad Pr
Butylamine,	$C_8 H_{11} N$	=	NH_2, $C_8 H_9$	=	Ad Bu
Amylamine,	$C_{10} H_{13} N$	=	NH_2, $C_{10} H_{11}$	=	Ad Ayl

and so on throughout the whole series of radicals.

No series is more striking than this. Its discovery was predicted by Liebig exactly ten years before it was made, and the properties of the compounds belonging to it plainly indicated. The analogy to ammonia is so perfect, that the base nearest to ammonia, methylamine, can hardly be distinguished from it. It is, like ammonia, a gas, absorbed in large quantity by water, of a pungent smell, almost identical with that of ammonia; it forms white fumes with hydrochloric acid, and its salts exactly resemble those of ammonia. It occurs in various decompositions, and in putrefaction, along with ammonia, and it has been frequently taken for ammonia and described as such before its true nature was known. Ethylamine is only a degree less like ammonia, being at ordinary temperatures a very volatile liquid, the smell of which, while analogous to that of ammonia, yet differs from it. It also has been often overlooked from this resemblance. As in all other series, the compounds higher in the scale are less and less volatile and more oily, and at a certain point become solid and crystalline. Not only do these bases form as many new homologous series as there are acids to combine with them, but with them all the reactions of ammonia may be repeated, giving rise to new compounds. Thus, ammonia forms four or five new bases with platinum; so do these volatile bases, methylamine and ethylamine, so that each of these four or five platinum bases represents a new series, and each of their salts with acids represents another. Thus not only do the sulphates of methylamine, &c., form a series, but the sulphate of each of the four or five platinum bases of ammonia does so likewise. And so of all the other salts. The bases of the series are called amide bases.

16. The sixteenth is also one of volatile bases, but not containing amide. Ammonia is still the type, but in this case it is viewed as composed of NH, H_2, or of imide NH, with 2 eqs. of hydrogen. The homologous bases of this series consist of imide with 2 eqs. of methyle, or of ethyle, &c.; or of imide with 1 eq. of methyle and 1 of ethyle, or 1 eq. of ethyle, and 1 of propyle, &c. &c. The following list contains a few of them:—

Ammonia,	$H_3 N$	=	NH, H_2	=	Id, H_2
Dimethylamine,	$C_4 H_7 N$	=	NH, 2 ($C_2 H_3$)	=	Id, Me_2
Diethylamine,	$C_8 H_{11} N$	=	NH, 2 ($C_4 H_5$)	=	Id, Ae_2
Dipropylamine,	$C_{12} H_{15} N$	=	NH, 2 ($C_6 H_7$)	=	Id, Pr_2
Methylethylamine,	$C_6 H_9 N$	=	NH, $C_2 H_3$, $C_4 H_5$	=	Id, Me Ae
Ethylopropylamine,	$C_{10} H_{13} N$	=	NH, $C_4 H_5$, $C_6 H_7$	=	Id, Ae Pr

and so on. These bases are very much similar to the others. They are called imide bases, and their general formula is $NH, 2 (C_n H_{n+1})$. It will be seen by the first column, that several of them are isomeric with amide bases, but the second and third columns, which give the rational formulæ, show that they are distinct in constitution as they are in properties, although analogous. It must be observed that the general formula of this series $NH, 2 (C_n H_{n+1})$, may also be written $(C_n H_{n+3}) N$, which is the same as that of the preceding series in its second form. The same general form also $(C_n H_{n+3}) N$, includes also the next series, although it also may be expressed so as to show the difference.

17. The seventeenth series is again one of volatile bases, of the type of ammonia, and of the general formula $(C_n H_{n+3}) N$, agreeing in this with the two preceding series, as has just been stated. But the more precise formula here is that which is taken from ammonia, viewed, not as amide + 1 eq. hydrogen, nor as imide + 2 eqs. hydrogen, but as nitrogen + 3 eqs. hydrogen, $N + H_3$. This being the type, in these bases the whole 3 eqs. of hydrogen are replaced by methyle, or by ethyle, &c., or partly by one and partly by another of the radicals of series 1. The following are some of them. Their general formula, strictly stated, is $N + 3 (C_n H_{n+1})$

Ammonia	$H_3 N$	=	$N + H_3$	=	$N H_3$
Trimethylamine	$C_6 H_9 N$	=	$N + 3 (C_2 H_3)$	=	$N Me_3$
Triethylamine	$C_{12} H_{15} N$	=	$N + 3 (C_4 H_5)$	=	$N Ae_3$
Triamylamine	$C_{30} H_{33} N$	=	$N + 3 (C_{10} H_{11}$	=	$N Ayl_3$
Methylodiethylamine	$C_{10} H_{13} N$	=	$N + C_2 H_3 + 2 (C_4 H_5)$	=	$N Me Ae_2$
Ethylodiamylamine	$C_{24} H_{27} N$	=	$N + C_4 H_5 + 2 (C_{10} H_{11})$	=	$N Ae Ayl_2$
Methylethylamylamine	$C_{16} H_{19} N$	=	$N + C_2 H_3 + C_4 H_5 + C_{10} H_{11}$	=	$N Me Ae Ayl$

Even among the few here given, it will be seen that three are isomeric with bases in the last table, and two of these also with two bases in the first table, series 15. But the rational formulæ in the last two columns show that they differ in constitution, as they do also in properties. The bases of this series are called nitryle bases.

The three series just mentioned, of all of which ammonia is the type, include all the known *volatile* organic bases, natural or artificial, that is, all such as are not decomposed but volatilized, unchanged by a due application of heat. An amide base is easily converted into an imide base by the action of the iodide of one of the radicals of series 1, and an imide base is converted by the same means into a nitryle base. And all of them may be derived from ammonia by the action, in successive steps, of such an iodide. Let us take iodide of ethyle, $Ae I$. The first action is $NH_3 + Ae I = NH_2 Ae, HI$. That is, the iodine takes 1 eq. of hydrogen, forming hydriodic acid, while the ethyle replaces that eq. of hydrogen, forming the amide base, ethylamine, which combines with the hydriodic acid. The next step is the action of iodide of ethyle on ethylamine, $NH_2 Ae + Ae I = NH Ae_2, HI$; the result is, hydriodate of diethylamine. And in the third stage, when iodide of ethyle acts on diethylamine, we obtain the hydriodate of triethylamine, $NH Ae_2 + Ae I = N Ae_3, H I$. Nothing can show more plainly that all these bases are simply ammonia, the hydrogen of which is replaced, in part or in whole, by positive radicals of series 1. It is also evident, that since there are only 3 eqs. of hydrogen in ammonia, we cannot push further the substitution of these radicals for hydrogen, after we have replaced the whole 3 equivalents. If we attempt to do so, we find that we obtain indeed new bases, but of a different type, being no longer volatile, but decomposed by heat, and containing oxygen. The explanation of this is very interesting. We cannot indeed replace more than three atoms of hydrogen in ammonia by our radicals, but we can add to the 3 eqs. of radical a fourth, and no more, or, in other words, we can replace the fourth eq. of hydrogen also in *ammonium*, which contains 4 eqs. of hydrogen. This leads to the formation of the next series.

18. The eighteenth series is a most remarkable and interesting one, of fixed bases, that is, bases which cannot be volatilized without decomposition, and which no longer are of the type ammonia, but, in composition, of the type of hydrated oxide of ammonium; and as that body is unknown in a separate form, we can compare them to nothing so well as to hydrated oxide of potassium, or caustic potash, to which they are in a most astonishing degree analogous. To illustrate their formation, let us suppose iodide of ethyle to act on triethylamine. Here there is no more hydrogen left to be replaced, for all 3 eqs. are already replaced, and all the hydrogen present is in the form of ethyle. The action is $N Ae_3 + Ae I = N Ae_4 I$. The ethyle of the iodide unites with triethylamine to form a compound metal, tetrethylium, $N Ae_4$, analogous to ammonium, NH_4, and this metal unites with the iodine, forming the iodide of tetrethylium, $N Ae_4 I$, exactly similar to iodide of ammonium, $NH_4 I$. To obtain the base, this iodide, which is a crystallizable salt, is acted on by oxide of silver and water. The action is, $N Ae_4 I + Ag O + HO = Ag I + N Ae_4 O, HO$; and the results are, iodide of silver and hydrated oxide of tetrethylium. The latter is obtained as a crystalline mass by evaporation *in vacuo*.

In composition, it corresponds to the hydrated oxides of ammonium and potassium. We have—

Hydrated oxide of ammonium...	$NH_4 O, HO$	=	$Am O, HO$
... ... potassium... ..			KO, HO
... .. tetrethylium..	$NAe_4 O, HO$	=	$Tth O, HO$

($Tth = NAe_4$, tetrethylium). Hydrated oxide of ammonium is not known, as, when we attempt to separate it from the salts of ammonium, it is instantly resolved into ammonia and water. $NH_4 O, HO = NH_3 + 2 HO$. The reason of this would seem to be, that the attraction of the oxygen of the oxide for the fourth eq. of hydrogen is so strong as to detach it, that eq. being of course held by a feebler force than the others. If, however, this hydrated oxide could exist in a separate form—and possibly we may some day succeed in obtaining it, perhaps under the influence of intense cold—it would certainly resemble caustic potash, and the hydrated oxide of tetrethylium. The latter can exist in a separate form, just because the attraction of oxygen for the fourth eq. of ethyle is very much less than for hydrogen; that is, at ordinary temperatures; for at higher temperatures hydrated oxide of tetrethylium undergoes precisely the same change as that of ammonium at ordinary temperatures, being converted into ethylamine, corresponding to ammonia, and hydrated oxide of ethyle, corresponding to 2 eqs. of water. $NAe_4 O, HO = NAe_3, + Ae O, HO$. It is on this account that we conjecture that under intense cold the ammonium compound might be permanent. The action of heat on this hydrated oxide of tetrethylium is characteristic of this whole series of bases.

In properties, hydrated oxide of tetrethylium is so very like caustic potash, that were it not for the action of heat, it might, in solution, be confounded with it. It has a caustic alkaline taste, feels soapy to the fingers, as potash does, attracts water and carbonic acid from the atmosphere, precipitates the salts of metals as potash does, converts oils into soaps when boiled with them, and forms insoluble or sparingly soluble salts, with bichloride of platinum and other tests, exactly as potash does. The chief difference is, that besides the caustic alkaline taste, it has a bitter taste; and this is true of the whole class of bases to which it belongs. This and the action of heat distinguish them from potash and soda. But these same characters connect them with the fixed vegetable bases, such as quinine, morphine, strych-

nine, and the like; all of which are bitter, and all of which, when heated, yield a volatile nitryle base, as the base in question yields triethylamine. In short, the bases of this series are of the same type as the fixed vegetable bases, and this being so, it is easy to see that there is no improbability in our being able to form artificially the natural fixed organic bases. Before going farther, we shall here give the formulæ of a few of the artificial bases of this series, the general formula of which is $N, 4 (C_n H_{n+1}) O, HO$. They are called ammonium bases.

Hydrated oxide of ammonium (type)	NH_4, O, HO		$= Am O, HO$
Hydrated oxide of tetramethylium	$C_8 H_{13} NO_2$	$= NMe_4 O, HO$	$= Tme O, HO$
tetrethylium	$C_{16} H_{21} NO_2$	$= NAe_4 O, HO$	$= Tth O, HO$
. . tetramylium	$C_{40} H_{45} NO_2$	$= NAyl_4, O, HO$	$= Aym O, HO$

To show the analogy in composition with the natural fixed bases, let us take the formula of quinine, which is $C_{20} H_{12} NO_2$, which is intermediate between the second and third of those above given. But, in addition to this, there exists a volatile base, found in coal-tar, and formed also by the action of heat on quinine, and bearing to it the same relation that trimethylamine does to hydrated oxide of tetramethylium. It is called quinoline, and is a nitryle base. Now, by the action of iodide of methyle, it is converted into an ammonium base, as follows. Its formula is $C_{18} H_8 N$. Now, $C_{18} H_8 N + C_2 H_3 I = C_{20} H_{11} N, I$. This iodide, acted on by oxide of silver, yields the base, $C_{20} H_{11} NO, HO = C_{20} H_{12} NO_2$, which is either quinine or a base isomeric with quinine. It is such considerations which render the ammonium bases so interesting, and we have dwelt somewhat fully on them, as well as on the amide, imide, and nitryle bases, because of the insight thus obtained into the mode of formation of two very important classes of vegetable products, the volatile bases, and the fixed bases. We have dwelt, however, only on the principles which regulate these very curious and important reactions, and not on the individual compounds, which our space forbids us to do. There is no part of the science which so plainly demonstrates the value and importance of the laws we have endeavoured to explain concerning types, substitution, and homologous series. Yet the whole of the facts in reference to these four series of bases are of quite recent discovery, ethylamine and methylamine dating only from 1840, while the imide, nitryle, and ammonium bases have all been discovered much more recently. There is every reason to expect important practical applications of these discoveries; but even should this not be the case, they have already done more for the science than hundreds of practical applications could ever do.

We shall now turn to a group of homologous series, related to those we have described, but more particularly to a series of negative radicals, derived from the compounds of the positive radicals of series 1.

19. The nineteenth series here specified, is that of the derived or positive radicals themselves. They are little if at all known in the separate state, but may be traced in many compounds, and therefore it is convenient to assume their existence. They are derived, that is, their compounds are derived, from those of the positive radicals, by the removal of 2 eqs. of hydrogen, which is effected by oxidizing agencies, by chlorine, and otherwise. Their general formula is $C_n H_{n-1}$; and the following are the first in the series—

Formyle...........	$C_2\ H$	=	Methyle	$C_2 H_3$	−	H_2
Acetyle...	$C_4\ H_3$	=	Ethyle	$C_4 H_5$	−	H_2
Propionyle.	$C_6\ H_5$	=	Propyle	$C_6 H_7$	−	H_2
Butyryle.......... .	$C_8\ H_7$	=	Butyle	$C_9 H_9$	−	H_2
Valeryle...........	$C_{10}\ H_9$	=	Amyle	$C_{10} H_{11}$	−	H_2

and so on, regularly.

20. The twentieth series is that of the hydrated protoxides of these negative radicals, the general formula of which is $(C_n H_{n-1}) O, HO = C_n H_n O_2$. The type of this series is aldehyde, $C_4 H_3 O, HO = C_4 H_4 O_2$, the hydrated oxide of acetyle. It is called aldehyde, because it is obtained from alcohol by dehydrogenation, for alcohol, $C_4 H_5 O, HO - H_2 = C_4 H_3 O, HO$.

Aldehyde is formed whenever alcohol is acted on by oxygen, the first effect being the removal of 2 eqs. of hydrogen, converted by the oxygen into water. Thus, $C_4 H_5 O, HO + O_2 = 2 HO + C_4 H_3 O, HO$. Aldehyde is a very volatile, pungent, inflammable liquid, having a strong attraction for oxygen, and reducing the salts of silver to the metallic state by this attraction. With 2 eqs. of oxygen it forms pure acetic acid, which is the teroxide of the same radical of which aldehyde is the protoxide. $C_4 H_3 O, HO + O_2 = C_4 H_3 O_3, HO$.

The whole series of homologous compounds, which, as a class, are called the aldehydes, agree with this one in their derivation, and in their attraction for oxygen, by which they are converted into volatile acids homologous with acetic acid. Several of them are found in nature, and others are formed in various processes. There are two remarkable characters which are found in all aldehydes, even in such as belong to a different series. But here we speak only of that series of aldehydes which is derived from the ethylic series of alcohols, and yields the acetic series of acids. These characters are, that the aldehydes combine with ammonia, forming in several cases permanent, crystallizable compounds; and that they also form crystalline compounds with the sulphites of potash or ammonia. By one or other of these characters aldehydes are detected when mixed with compounds of different properties, and may be purified. But their most important character is that of absorbing oxygen from the air, and producing the volatile and oily acids of the next series.

The following are a few of the aldehydes:—

Hydrated oxide of	formyle....	$C_2\ HO, HO$	=	$C_2\ H_2\ O_2$
Do.	acetyle.....	$C_4\ H_3\ O, HO$	=	$C_4\ H_4\ O_2$
Do.	propyle.....	$C_6\ H_5\ O, HO$	=	$C_6\ H_6\ O_2$
Do.	butyryle...	$C_8\ H_7\ O, HO$	=	$C_8\ H_8\ O_2$
Do.	valeryle...	$C_{10}\ H_9\ O, HO$	=	$C_{10}\ H_{10}\ O_2$
Do.	œnanthyle	$C_{14}\ H_{13}\ O, HO$	=	$C_{14}\ H_{14}\ O_2$
Do.	capryle ..	$C_{20}\ H_{19}\ O, HO$	=	$C_{20}\ H_{20}\ O_2$

These and some others are known. The two last-named are found, the former among the products of distillation of castor oil, the latter in the volatile oil of rue.

21, 22. The next, or twenty-first series, is that of the hydrated teroxides of the negative or formylic radicals, which are volatile, and with the exception of two, oily and fatty acids of great interest and importance. Their general formula is $C_n H_{n-1} O_3, HO = C_n H_n O_4$. They are found abundantly in nature, generally combined with oxide of lipyle or glycerine, forming the fixed oils and fats; but they also occur free, and some of them combined with oxide of ethyle. These acids are formed by the direct oxidation of the aldehydes, which, as we have seen, are themselves formed by the action of oxygen on the alcohols, which removes hydrogen from these compounds. Hence the typical process, which is the conversion of common alcohol into acetic acid, consists of two stages, the production of aldehyde by dehydrogenation, and the oxidation of the aldehyde thus produced. Representing alcohol by $C_4 H_6 O_2$ for shortness' sake, we have first $C_4 H_6 O_2 + O_2 = 2 HO + C_4 H_4 O_2$; and secondly aldehyde, which is $C_4 H_4 O_2$, taking up 2 eqs. of oxygen, becomes acetic acid, $C_4 H_4 O_4 = C_4 H_3 O_3, HO$. It is in this way, and no other, that alcohol, wine, or beer, is converted into vinegar. If the supply of oxygen be deficient, great loss is sustained by the evaporation of the very volatile aldehyde, but with a full supply of oxygen the whole is acidified. As this oxidation, or slow combustion, or decay, of alcohol is set agoing by contact with a ferment, such as yeast, and air at the same time, it has been called the acetous fermentation; but it is merely a case of oxidation or

decay promoted by the presence of a ferment, as will be elsewhere explained.

Of all known homologous series, this one is the best known and the most complete, the series being unbroken from C_2 (in formic acid), to C_{42} (in behenic acid), and at least two acids being known beyond that point. We give here the list of these acids, premising that the two first, which contain, relatively, a very large amount of oxygen, are not oily, but that oily properties begin to appear in the third, and that all the rest are oily and fatty, exhibiting a perfect gradation of physical properties, such as density, fusibility, volatility, &c.; being, in short, a perfect example of a homologous series.

	Formic acid	$C_2\,H\,O_3, HO = C_2\,H_2\,O_4$
	Acetic acid	$C_4\,H_3\,O_3, HO = C_4\,H_4\,O_4$
Oily acids.	Propylic acid	$C_6\,H_5\,O_3, HO = C_6\,H_6\,O_4$
	Butyric acid	$C_8\,H_7\,O_3, HO = C_8\,H_8\,O_4$
	Valerianic acid	$C_{10}\,H_9\,O_3, HO = C_{10}\,H_{10}\,O_4$
	Caproic acid	$C_{12}\,H_{11}\,O_3, HO = C_{12}\,H_{12}\,O_4$
	Œnanthylic acid	$C_{14}\,H_{13}\,O_3, HO = C_{14}\,H_{14}\,O_4$
	Caprylic acid	$C_{16}\,H_{15}\,O_3, HO = C_{16}\,H_{16}\,O_4$
	Pelargonic acid	$C_{18}\,H_{17}\,O_3, HO = C_{18}\,H_{18}\,O_4$
Fatty acids.	Capric acid	$C_{20}\,H_{19}\,O_3, HO = C_{20}\,H_{20}\,O_4$
	Margaritic acid	$C_{22}\,H_{21}\,O_3, HO = C_{22}\,H_{22}\,O_4$
	Laurostearic acid	$C_{24}\,H_{23}\,O_3, HO = C_{24}\,H_{24}\,O_4$
	Cocinic acid	$C_{26}\,H_{25}\,O_3, HO = C_{26}\,H_{25}\,O_4$
	Myristic acid	$C_{28}\,H_{27}\,O_3, HO = C_{28}\,H_{28}\,O_4$
	Benic acid	$C_{30}\,H_{29}\,O_3, HO = C_{30}\,H_{30}\,O_4$
	Cetylic and Palmitic acids	$C_{32}\,H_{31}\,O_3, HO = C_{32}\,H_{32}\,O_4$
	Margaric acid	$C_{34}\,H_{33}\,O_3, HO = C_{34}\,H_{34}\,O_4$
	Bassic and Stearic acids	$C_{36}\,H_{35}\,O_3, HO = C_{36}\,H_{36}\,O_4$
	Balenic acid	$C_{38}\,H_{37}\,O_3, HO = C_{38}\,H_{38}\,O_4$
	Butinic acid	$C_{40}\,H_{39}\,O_3, HO = C_{40}\,H_{40}\,O_4$
	Behenic acid	$C_{42}\,H_{41}\,O_3, HO = C_{42}\,H_{42}\,O_4$
Waxy acids.	Cerotic acid	$C_{54}\,H_{53}\,O_3, HO = C_{54}\,H_{54}\,O_4$
	Melissic acid	$C_{60}\,H_{59}\,O_3, HO = C_{60}\,H_{60}\,O_4$

The acids of this truly remarkable series are all volatile, that is, may all be distilled unchanged, but the boiling point rises at each step just as with the alcohols, and to the same extent, namely, about 34° for each addition of $C_2\,H_2$. The two first are products of oxidation, usually artificial, but formic acid occurs in the ant, and acetic acid in some vegetable juices. The remaining acids are all found in nature, and in general, combined with oxide of lipyle, $C_3\,H_2\,O$, or $C_6\,H_4\,O_2$, forming the neutral fixed oils and fats, vegetable and animal. Of the former, olive oil and palm oil are examples; of the latter, tallow and butter. These fats and oils, however, contain also a peculiar oily acid, not of this series, combined also with oxide of lipyle. This is oleic acid, $C_{36}\,H_{33}\,O_3, HO = C_{36}\,H_{34}\,O_4$. The most abundant of the oils and fats are those containing oleic acid, stearic acid, palmitic acid, and margaric acid, which seems to be a compound, possibly a mixture of stearic and palmitic acids. The oils containing the acids lower in the scale, from C_8 to C_{20}, which are the more volatile of the oily acids, occur only in certain fats, and in small quantities, and give them their peculiar flavour, the fats higher in the scale having neither taste nor smell. The neutral fats are named shortly, after the acids they contain; thus, oleine, stearine, palmitine, margarine, butyrine, valerine, caproine, &c. Solid fats consist chiefly of stearine, palmitine, margarine, &c., with a little oleine; liquid oils of oleine, with some margarine, stearine, &c., dissolved. Butter is a very remarkable fat, containing butine, stearine, palmitine, and myristine, the stearine and palmitine together forming margarine, all of these being solid tasteless fats; and, in smaller quantity, caprine, capryline, caproine, and butyrine, which are oily and sapid, and give to butter its peculiar flavour, especially butyrine, the most abundant of them. It contains also oleine. But it is worthy of notice, that all the acids of the formic series in butter have formulæ in which the number of atoms of carbon is divisible by 4, none of the intermediate acids being present. Valerine is the compound which, being present in small quantity in whale oil, as butyrine is in butter, gives to that oil its peculiar and unpleasant flavour. When the neutral fat oils, such as stearine, palmitine (which constitutes the chief part of palm oil), margarine, and oleine, are boiled with alkalies, they yield soaps, which are compounds of the oily and fatty acids with potash and soda, the former yielding soft, the latter hard soaps. In this process the basic oxide of lipyle is separated, and combining with water, forms a sweetish solution, which by evaporation forms a syrup, called glycerine, or the sweet principle of oils. Oxide of lipyle is $C_3\,H_2\,O$, and glycerine is $2\,(C_3\,H_2\,O) + 3\,HO = C_6\,H_7\,O_5$. When glycerine is heated in sealed tubes with the oily acids, it again becomes oxide of lipyle and combines with the acids, reproducing neutral oils or fats. When heated by itself glycerine yields an intolerably acrid pungent vapour, which condenses into a liquid called acroleine, or hydrated oxide of acryle, $C_6\,H_3\,O, HO = C_6\,H_4\,O_2$. It appears to be either oxide of lipyle, which we have seen to be $C_3\,H_2\,O$, or $C_6\,H_4\,O_2$, or polymeric with it, the latter being the more probable view. It attracts oxygen with avidity, and is converted into an acid, acrylic acid, $C_6\,H_3\,O_3, HO = C_6\,H_4\,O_4$ resembling acetic acid. In consequence of the formation of acroleine, the action of heat on oils is an excellent means of detecting the presence in them of oxide of lipyle or glycerine. A drop of any oil containing that compound, heated in the bottom of a test tube, produces the pungent vapour of acroleine which attacks the eyes strongly, and is indeed formed, as all must have perceived, when a candle is blown out so as to leave the wick ignited, that is red-hot, without flame.

The reader will perceive that we have taken this opportunity of giving a brief general sketch of the oils and fats; and have, in fact, appended to the homologous series of the oily acids the description of another series, No. 22, which includes the compounds of those acids with oxide of lipyle or glycerine, that is, the neutral oils and fats. We trust that this brief notice will suffice to give the student an idea of the chemistry of both of these very important series, the oily and fatty acids, and the neutral oils and fats. It will also serve to illustrate the advantage of studying homologous series, since otherwise this numerous class of bodies would present only a mass of confusion.

23. The next, or twenty-third series we shall name is that of the salts formed by the acids of series 21 with oxide of ammonium. We shall not, however, enter into details, but only state, that from this series two others arise by the separation of water. As an example of the series itself, we take acetate of ammonia, $NH_4\,O, C_4\,H_3\,O_3$. General formula $NH_4\,O + (C_n\,H_{n-1})\,O_3$.

24. The twenty-fourth series is derived from the preceding by the separation of 2 eqs. of water, and includes the amides of the acids of series 21. Example acetamide, which is acetate of ammonia, *minus* 2 eqs. of water, $NH_4\,O, C_4\,H_3\,O_3 - 2\,HO = NH_2, C_4\,H_3\,O_2 = C_4\,H_5\,NO_2$. General formula $NH_2 + C_n\,H_{n-1}\,O_2$.

25. The twenty-fifth series is derived either from the twenty-third, by the separation of 4 eqs., or from the twenty-fourth by that of 2 eqs. of water, by which all oxygen is removed from both, and the result is a series of very remarkable volatile liquids, called nitryles, and containing the elements of one of the negative radicals, with 1 eq. of nitrogen. Take for example acetonitryle, which is thus derived from acetate of ammonia. $NH_4\,O, C_4\,H_3\,O_3 - 4\,HO = C_4\,H_3\,N$, or from acetamide; $NH_2, C_4\,H_3\,O_2 - 2\,HO = C_4\,H_3\,N$.

The most important point in regard to this series is, that in composition they are either niturets of the formylic radicals, or cyanides of the methylic radicals one step lower in the scale. Thus acetonitryle is either $C_4\,H_3, N$, or $C_2\,H_3, C_2\,N$, which latter formula is cyanide of methyle.

Now it is not yet certain whether in all cases the nitryles, as obtained from the ammonia salts of the acids of the formic series, are really the cyanides of ethylic radicals, or only

isomeric with them. In some cases they certainly appear to be identical with these cyanides as otherwise obtained, but in others they seem to be different. Supposing them to be the cyanides, then it will be possible from any acid of the series No. 21 to obtain the cyanide of the ethylic radical, having 2 eqs. of carbon less than the acid, as from acetic acid cyanide of methyle. Now from the cyanides we can reproduce the alcohol from which they are derivable. And thus we may probably be able to form artificially alcohols which otherwise might never be known. For example, the alcohol with 30 eqs. of carbon is unknown; but from the ammonia salt of the acid with 32 eqs. of carbon, palmitic acid, we can obtain the body palmitonitryle $C_{32}\,H_{31}\,N$, which is probably the cyanide of the radical $C_{30}\,H_{29}$. And if so, from this cyanide it might be possible to form the alcohol in question, which contains the radical $C_{30}\,H_{31}$. The general formula of the nitryles is $C_n\,H_{n-1}\,N$ or $C_n\,H_{n+1} + C_2\,N$.

26. The next, or twenty-sixth series, will be that of the terchlorides of the formylic radicals, of which chloroform, the terchloride of formyle is the type. The properties of chloroform are now well known. At present no other member of this series has been studied, but judging from that one they merit investigation. General formula $C_n\,H_{n-1}, Cl_3$.

27. The oil of olefiant gas, or of the Dutch chemists, represents a twenty-seventh series. It is the hydrochlorate of a protochloride of acetyle, $C_4\,H_3\,Cl, H\,Cl = C_4\,H_4\,Cl_2$. Of this series also hardly any others are known. The oil in question has a singular resemblance to chloroform in its taste and smell, as well as in its action on the system when inhaled. General formula, $C_n\,H_{n-1}\,Cl$, $H\,Cl$.

28. The twenty-eighth series is that of the hydurets of the formylic radicals, the type of which is olefiant gas, or hyduret of acetyle, $C_4\,H_3, H = C_4\,H_4$. This is a series of combustible gases, liquids, and solids, formed abundantly in the distillation of organic substances, such as wood, coal, or animal matter, along with the hydurets of the methylic radicals, typified by marsh gas $C_4\,H_6$. It is probable that several species of naphtha and of paraffine belong to this series, as well as to series 4. The compounds of this series, No. 27, are absorbed by chlorine even in the dark, which is not the case with those of series 4.

29. The next or twenty-ninth series is very remarkable; it is that of which oxalic acid is the type, and consists of bibasic acids, having a singular relation to the acids of series 21. Oxalic acid is $C_4\,O_6, 2\,HO = C_4\,H_2\,O_8$. Now, if we compare this with the formula of formic acid, $C_2\,H_2\,O_4$, we perceive that they differ exactly by $C_2\,O_4$, that is, by 2 eqs. of carbonic acid; so that, to obtain the formulæ of the acids of this series, we have only to add $C_2\,O_4$ to those of the acids of series 20, thus—

Monobasic volatile acids.				Bibasic fixed acids.	
Formic acid,	$C_2\,H_2\,O_4$	$+\,C_2\,O_4$	$=$	$C_4\,H_2\,O_8$	oxalic acid.
Acetic acid,	$C_4\,H_4\,O_4$	$+\,C_2\,O_4$	$=$	$C_6\,H_4\,O_8$	?
Propylic acid,	$C_6\,H_6\,O_4$	$+\,C_2\,O_4$	$=$	$C_8\,H_6\,O_8$	succinic acid.
Butyric acid,	$C_8\,H_8\,O_4$	$+\,C_2\,O_4$	$=$	$C_{10}\,H_8\,O_8$	lipic acid.
Valerianic acid,	$C_{10}\,H_{10}\,O_4$	$+\,C_2\,O_4$	$=$	$C_{12}\,H_{10}\,O_8$	adipic acid.
Caproic acid,	$C_{12}\,H_{12}\,O_4$	$+\,C_2\,O_4$	$=$	$C_{14}\,H_{12}\,O_8$	pimelic acid.
Œnanthylic acid,	$C_{14}\,H_{14}\,O_4$	$+\,C_2\,O_4$	$=$	$C_{16}\,H_{14}\,O_8$	suberic acid.
Caprylic acid,	$C_{16}\,H_{16}\,O_4$	$+\,C_2\,O_4$	$=$	$C_{18}\,H_{16}\,O_8$	?
Pelargonic acid,	$C_{18}\,H_{18}\,O_4$	$+\,C_2\,O_4$	$=$	$C_{20}\,H_{18}\,O_8$	sebacic acid.

It will be seen that up to C_{20}, there are only two blanks in this series; and it is a proof of their close relation to the oily volatile acids, that every one of these, except perhaps the last, is formed, along with the parallel oily acids, in the oxidation of fats and fatty acids by means of nitric acid. It is only very recently that these relations have been recognised and the series established; and as it includes oxalic acid, one of the commonest acids in plants, we are entitled to expect that the progress of science will develop series in which the other acids of acid fruits and leaves will find their place. We have another proof of the close relation between these two series of acids, the formic series and the oxalic series, in the fact that oxalic acid, when heated, yields formic and carbonic acids, which, in the above table, are shown to exist in it by their elements at least. This is, indeed, one of the best methods of obtaining formic acid. It seems probable that we shall succeed in applying the same method to obtain from the other acids of the oxalic series the oily acids parallel to them, as, for example, œnanthylic acid. from suberic acid, and the rare pelargonic acid from sebacic acid. This, however, has not yet been done. Sebacic acid is formed when oleic acid is distilled, and the production of it by heat is an excellent test of the presence of oleine in any oil or fat. The oxalic series of acids are all bibasic, and their general formula is $C_n\,H_{n-2}\,O_8 = C_n\,H_{n-4}\,O_6, 2\,HO$.

30. The next, or thirtieth series, is that of the cyanates of the oxides in series 2. The type is cyanic acid, which is remarkable for its transformation into urea, when combined with ammonia. Besides this, when heated with potash, it yields carbonic acid and ammonia, $C_2\,NO, HO + 2\,KO, HO = 2\,(KO, CO_2) + NH_3$. Now, the homologous cyanates of oxides of methyle, ethyle, &c., will undergo the same transformations. By the latter, heating with potash, they yield, instead of ammonia, the homologous bases, methylamine, ethylamine, &c., which were discovered by Wurtz in this way. The former metamorphosis, that is, with ammonia, gives rise to the next series, which is a very remarkable one. It is unnecessary to dwell longer on these cyanates, the general formula of which is $(C_n\,H_{n+1})\,O, C_2\,NO$.

31. The thirty-first series is that of which urea is the type. And here we have another example of the comprehensiveness of the principle of homologous series. Urea has long been considered as an isolated body, without any visible relation to others, and now we find that, viewed in the light of the principle alluded to, it is a type of a numerous class of compounds, the discovery of which is due to that principle. The following are the first members of this series:—

Cyanic acid, with ammonia—

$C_2\,NO, HO, NH_3$, yields $C_2\,H_4\,N_2\,O_2$, urea.

Cyanate of oxide of methyle, with ammonia—

$C_2\,NO, C_2\,H_3\,O_4, NH_3$, yields $C_4\,H_6\,N_2\,O_2$, methylo-urea.

Cyanate of oxide of ethyle, with ammonia—

$C_2\,NO, C_4\,H_5\,O, NH_3$, yields $C_6\,H_8\,N_2\,O_2$, ethylo-urea.

Cyanate of oxide of amylo, with ammonia—

$C_2\,NO, C_{10}\,H_{11}\,O, NH_3$, yields $C_{12}\,H_{14}\,N_2\,O_2$, amylo-urea.

The perfect analogy which here prevails is fully seen, if we consider hydrated cyanic acid as cyanate of oxide of hydrogen, and the cyanates of oxide of methyle, &c., as compounds in which methyle, &c., replace that hydrogen. The rational formula of urea is not certainly known, but as it is basic, we may suppose it to represent 2 equivalents of ammonia, in which 2 equivalents of hydrogen are replaced by CO, or carbonic oxide, thus: $N_2\,H_6 = 2$ eqs. ammonia, and urea $= N_2 \left.\begin{matrix} H_4 \\ C_2\,O_2 \end{matrix}\right\}$ or $N_2 \left.\begin{matrix} H_4 \\ (CO)_2 \end{matrix}\right\}$ we shall thus have—

Urea .... $N_2 \left.\begin{matrix} H_4 \\ (CO)_2 \end{matrix}\right\}$

Methylo-urea.......................... $N_2 \left.\begin{matrix} H_3 \\ C_2\,H_3 \\ (CO)_2 \end{matrix}\right\}$

Ethylo-urea.......................... $N_2 \left.\begin{matrix} H_3 \\ C_4\,H_5 \\ (CO)_2 \end{matrix}\right\}$

Amylo-urea....... .... $N_2 \left.\begin{matrix} H_3 \\ C_{10}\,H_{11} \\ (CO_2) \end{matrix}\right\}$

The compounds of this series, homologous with urea, are perfectly analogous to it in properties. Urea, the type, is found ready formed in urine, and is produced artificially by the above-mentioned transformation of cyanate of ammonia. It crystallizes in prisms, which in form as well as in taste resemble nitre. It is soluble in alcohol, and forms with acids salts, being a weak base. The nitrate and oxalate

of urea are sparingly soluble, and crystallize readily. The action of heat on urea has been already explained, as well as its production, under the head of isomeric and polymeric transformations.

32. The next series we shall mention is that which consists of compounds of the aldehydes with ammonia. Only one of them, that composed of acetic aldehyde and ammonia, is well known; but there is no doubt of the existence of several others, the tendency to form such compounds being a character of the aldehydes. The best known of these compounds, aldehydammonia as it is called, is $NH_3, HO, C_4 H_3 O = C_4 H_7 NO_2$. It crystallizes readily, and undergoes some remarkable transformations. The general formula of this series is $C_n H_{n-1} O, HO, NH_3$. One of its transformations is that caused by sulphurous acid, of which 2 eqs. unite with 1 of aldehydammonia, or 1 eq. of aldehyde unites with 1 eq. of bisulphite of ammonia, to form the compound $NH_3, HO, C_4 H_3 O, 2 SO_2 = C_4 H_7 NS_2 O_4$. This compound is isomeric with taurine, a very remarkable substance obtained from bile. It is probable that this is one of a new homologous series.

33. The type of the next series is derived from formic aldehyde, by the action of hydrocyanic acid and water, $C_2 H_2 O_2 + C_2 NH + 2 HO = C_4 H_5 NO_4$. This last formula is that of a remarkable base, found in bile and elsewhere in the animal body, and from its sweet taste called glycocine, glycocoll, or sugar of gelatine. We prefer the first name. It is best obtained by boiling hippuric acid, an acid found in urine, with strong hydrochloric acid, when two eqs. of water are taken up, and it is resolved into benzoic acid and glycocine. Hippuric acid is $C_{18} H_9 NO_6$, and with 2 HO, it yields $C_{14} H_6 O_4$, benzoic acid, and $C_4 H_5 NO_4$, glycocine. Glycocine is a base, and forms crystallizable salts with acids, but it also forms crystalline compounds with bases and with neutral salts. Of the series of glycocine three only are as yet known, which are—

Glycocine....................	$C_4 H_5 NO_4$	$= NH_2, C_4 H_3 O_4$
Alanine................	$C_6 H_7 NO_4$	$= NH_2, C_6 H_5 O_4$
...	...	...
...	...	...
Leucine......................	$C_{12} H_{13} NO_4$	$= NH_2, C_{12} H_{11} O_2$

The last column represents these compounds as amides of the acids which constitute the next series. Alanine is obtained by the action of hydrocyanic acid on aldehyde. Leucine is found in the animal body, as is also glycocine. It cannot be doubted that other compounds of this series will be discovered, and they are likely to be compounds of much interest.

34, 35. The next series consists of acids, and the type is lactic acid. They are in so far connected with the aldehydes, that they consist of formic acid, coupled with the aldehydes. Thus we have—

		Aldehydes.	Formic Acid.
Glycolic acid.......	$C_4 H_4 O_6 =$	$C_2 H_2 O_2 +$	$C_2 H_2 O_4$
Lactic acid.........	$C_6 H_6 O_6 =$	$C_4 H_4 O_2 +$	$C_2 H_2 O_4$
Leucic acid..........	$C_{12} H_{12} O_6 =$	$C_{10} H_{10} O_2 +$	$C_2 H_2 O_4$

The two first acids, if regarded as monobasic, will be written thus—

Glycolic acid..........	$C_4 H_3 O_5, HO$	$= C_4 H_4 O_6$
Lactic acid.....	$C_6 H_5 O_5, HO$	$= C_6 H_6 O_6$

And their ammonia salts, *minus* 2 eqs. of water, according to the usual law, will give the amides, glycolamide and lactamide, which have the composition of glycocine and alanine, but seem to be only isomeric with them.

Glycolate of ammonia, $NH_3, HO, C_4 H_3 O_5 - 2 HO = C_4 H_3 O_4, NH_2$
Lactate of " $NH_3, HO, C_6 H_5 O_5 - 2 HO = C_6 H_5 O_4, NH_2$

The reason why these two amides are not identical with glycocine and alanine seems to be that the acids are really bibasic, and that therefore the true formulæ of the acids, as well as the amides, are double those just given.

Glycolic acid,..... $C_8 H_6 O_{10}, 2 HO$ Glycolamide $C_8 H_6 O_8, 2 NH_2$
Lactic acid,..... .. $C_{12} H_{10} O_{10}, 2 HO$ Lactamide $C_{12} H_{10} O_8, 2 NH_2$

It is probable that the amides form a distinct series by themselves. There is, besides, another series, strictly isomeric with the glycocine series, namely, the hyponitrites of the oxides of series 2.

Hyponitrite of oxide of	methyle,	$C_2 H_3 O, NO_3$	$= C_2 H_3 NO_4$
... ..	ethyle,	$C_4 H_5 O, NO_3$	$= C_4 H_5 NO_4$
.. ..	propyle,	$C_6 H_7 O, NO_3$	$= C_6 H_7 NO_4$
... ..	caprotyle,	$C_{12} H_{13} O, NO_3$	$= C_{12} H_{13} NO_4$

The analogue of the first of these in the glycocine series is unknown. The others are analogous to and isomeric with glycocine, alanine, and leucine. This may be called series 35.

36. Another series, isomeric with 33 and 35, is that of which the type is urethan or carbamate of oxide of ethyle. Carbamic acid is an acid amide, or bicarbonate of ammonia *minus* 2 eqs. of water. $(NH_3, HO, 2 CO_2) - 2 HO = C_2 H_2 NO_3$. This last is carbamic acid, and with oxide of methyle it forms a compound isomeric with glycocine. $C_2 H_3 O + C_2 H_2 NO_3 = C_4 H_5 NO_4$. The compound with oxide of ethyle is isomeric with alanine; that with oxide of amyle is isomeric with leucine.

There is still another compound, sarcosine, a base, which is isomeric with alanine, but whether it be one of a series we do not yet know.

37. Analogous to the last series is that of the compounds of oxamic acid with the oxides of series 2. They are beautifully crystallized bodies, as are also those of series 36, and are formed by the action of ammonia on the oxalates of the oxides of methyle, ethyle, &c. Oxamic acid is acid oxalate of ammonia, *minus* 2 eqs. of water. $(C_4 O_6, HO, NH_4 O) - 2 HO = C_4 H_2 NO_5 = C_4 H_3 NO_6, HO$, and with oxide of methyle, this acid, oxamic acid, forms the first of the new series. $C_2 H_3 O + C_4 H_2 NO_5 = C_6 H_5 NO_6$. This is sometimes called oxamethylan. The next one is oxamethan or oxamate of oxide of ethyle, $C_4 H_5 O, C_4 H_2 NO_5 = C_8 H_7 NO_6$.

38. The next series is one consisting of certain newly discovered acids, the two first of which are known. These contain glycolic and lactic acids, coupled with benzoic acid, and thus form a connecting link between the extensive group of allied homologous series now under consideration, and that group to which benzoic acid, its congeners, and their derivatives belong. These acids are—

Benzoglycolic acid, $C_{18} H_8 O_8 = C_4 H_3 O_5 + C_{14} H_5 O_3$
Benzolactic acid, $C_{20} H_{10} O_8 = C_6 H_5 O_5 + C_{14} H_5 O_3$

Benzoleucic acid, $C_{26} H_{24} O_{10}$, is said to exist, but has not yet been studied. The amides of these acids probably form a new series, only one of which is yet known.

39. This is hippuric acid, $C_{18} H_9 NO_6$, which is the amide of benzoglycolic acid; that is, benzoglycolate of ammonia, $(NH_3, C_{18} H_8 O_8)$, *minus* 2 eqs. HO, which gives $C_{18} H_9 NO_6$. This is a very remarkable acid, found in large quantity in the urine of herbivorous animals. When boiled with strong hydrochloric acid, it is first resolved, like other amides, into ammonia and the acid, which is here benzoglycolic acid, 2 eqs. of water being taken up. But the benzoglycolic acid is itself resolved into benzoic acid and glycolic acid, 2 eqs. of water being taken up, and the glycolic acid, acting on the ammonia, produces, with the separation of 2 eqs. of water, glycolamide or glycocine. So that the ultimate results of the operation are benzoic acid and glycocine. Hippuric acid as yet stands alone, but as we already know homologues both of benzoglycolic acid and of glycocine, it cannot be doubted that we shall in time discover homologues also of hippuric acid.

40. The next series we shall mention is that of which acetone is the type. When the salts of acetic acid are decomposed by heat, they yield carbonic acid, which remains combined with the base, and acetone which distils over. In

Chemistry. the case of acetate of lime we have $Ca\,O, C_4\,H_3\,O_3 = Ca\,O, CO_2 + C_3\,H_3\,O$. The true formula of acetone appears to be double of this, or $C_6\,H_6\,O_2$, and it is regarded by some as a hydrated oxide analogous to alcohol; that is, as $C_6H_5\,O, HO$. This analogy is far from close, but all the acids of the acetic series, at least above acetic acid, seem to form singular compounds, which are isomeric with the aldehydes of the acids next above each. Thus acetone is isomeric with propylic aldehyde. Various opinions are entertained as to the real nature, and even as to the formulæ of these compounds, but for the present we adopt the formulæ which give to all of them 2 eqs. of oxygen.

We now come to a group of homologous series, of very recent discovery, and as yet but little known, save in the case of one or two, but which indicate the existence of a very large number of compounds of the most remarkable composition and properties. These are the compounds in which the elements of the radicals of series 1 are combined with a certain class of metals, giving rise to new and most singular radicals or compound metals having most energetic affinities, and in their compounds very analogous to metals. We can only briefly mention the characters of these compounds.

41. The first series of this group is that which contains zinc. When iodide of methyle or ethyle is heated with zinc in a closed tube, there is formed a crystalline mass, consisting of iodide of zinc, along with the new radical, zinco-methyle in the former, zinco-ethyle in the latter case. On distilling the mass in hydrogen gas, iodide of zinc is left, and the new radicals distil over. They are volatile, fetid, spontaneously inflammable liquids, and appear to act as energetic positive radicals, analogous to metals, combining with oxygen, chlorine, sulphur, &c. They decompose water, producing oxide of zinc and the carbohydrogen of series 4. Thus with zinco-methyle, which is $C_2\,H_3\,Z_n$, and water HO, we have $Z_n\,O$ and $C_2\,H_4$; zinco-ethyle is $C_4\,H_5\,Z_n$, and zinco-amyle which has been formed, is $C_{10}\,H_{11}\,Z_n$. No other radicals of this series are yet known.

42. The next series contains antimony. It is formed by the action of an alloy of potassium and antimony on iodide of methyle or ethyle. The formula of stibiomethyle is $Sb\,Me_3 = Sb\,C_6\,H_9$. That of stibethyle is $Sb\,Ae_3 = Sb\,C_{12}\,H_{15}$. These properties resemble those of zinco-ethyle, and they are powerful radicals, of the class of metals.

43. This series also contains antimony. The formula of the first compound is $Sb\,Me_4 = Sb\,C_8\,H_{12}$, and it is called stibiomethylium. It is analogous to ammonium and potassium, and forms a hydrated oxide, resembling caustic potash.

44. The next series contains tin, and the compounds are called stannomethyle and stannoethyle. Their formulæ are $Sn\,C_2\,H_3 = Sn\,Me$ and $Sn\,C_4\,H_5 = Sn\,Ae$. They are analogous to the preceding.

45. In this series, 2 eqs. of the preceding one seem to be condensed into one, so that the formulæ are, $Sn_2\,C_4\,H_6 = Sn_2\,Me_2$, and $Sn_2\,C_8\,H_{10} = Sn_2\,Ae_2$. These also are powerful quasi-metallic radicals.

46. In the next series lead is the metal combined with the organic radicals. A compound has been described, consisting of $Pb_2\,Ae_3$, which, like the others is a positive radical, forming a base with oxygen, and salts with chlorine, iodine, &c. There seem to be several other radicals, formed of lead and ethyle, in different proportions. They are all liquid and fuming, and burn when kindled, producing thick fumes of oxide of lead. Each of the lead radicals will of course belong to a distinct series.

47. Tellurium also combines with ethyle to form one or more radicals. The best known is tellurethyle, $Te\,Ae = Te\,C_4\,H_5$. Another, which belongs to a different series, is $Te\,Ae_2$. They are both very fetid and poisonous liquids, and powerful radicals.

48. Arsenic forms similar compounds, both with ethyle and methyle. The best known of them is kakodyle, $As\,Me_2 = C_4\,H_6\,As$. This is a crystalline volatile substance, having all the chemical relations of a metal. Its protoxide is a volatile, fetid, spontaneously inflammable, and frightfully poisonous liquid, which is strongly basic. Its teroxide is an acid, and is devoid of smell and of poisonous action. Its compounds with chlorine, iodine, sulphur, cyanogen, &c., are all volatile, fetid, and poisonous. There are several other compounds of arsenic with methyle and ethyle, forming so many separate series, but as yet they are little known. Chemistry.

49. The next series we shall mention is typified by kakoplatyle, which consists of kakodyle, platinum, and water, or perhaps oxygen and water. It is also a positive radical, of the formula $C_4\,H_6\,As\,Pt\,O, HO$, and forms a hydrated oxide, a chloride, iodide, sulphuret, &c. &c.

50. In the next series, methyle and ethyle are combined with phosphorus. There are several compounds with each, and they appear to correspond to the compounds of phosphorus with hydrogen. The compound $P\,Me_2$, which corresponds to kakodyle, is like it a very fetid and poisonous liquid. Besides this, there are the radicals $P_2\,Me$, $PH_2\,Me$ and $P\,Me_3$, all of which are analogous to the first. Each of course indicates a separate series.

We have only indicated the existence of these very remarkable compounds of metals and phosphorus with radicals of the methylic series. Already they are very numerous, and they have all striking properties and strong affinities. New compounds of this class are daily discovered, and almost every new one is the first of a new series. Besides the metals we have named, bismuth and potassium are said to form similar compounds, not yet described. It will be seen that all the metals which have yet been found to unite with the methylic radicals are more or less volatile, and all the compounds are so, whereas the compounds of most of these metals with oxygen, chlorine, sulphur, &c., are fixed in the fire. Most of these compound radicals or compound metals are spontaneously inflammable in the air, from their strong attraction for oxygen, and most of them are poisonous in the highest degree, apparently because they bring the metals they contain in contact with the system in a very fine state of division.

We have now indicated most of the established homologous series, connected with the methylic radicals. It will be seen that these include a large number of important organic compounds, such as alcohol, ether, compound ethers, volatile and oily acids and their salts, volatile and fixed bases and their salts, carbohydrogens, amides, &c. There are, however, many compounds which cannot as yet be classified in this way. But before turning to these, we must mention another group of homologous series, not directly connected with the methylic radicals, but rather in some points running parallel to the series already described. This is the benzoic group, so called from benzoic acid, which is a characteristic feature of the group.

1. The first series of this group is that of which benzoic acid is the type. This acid is found ready formed in gum benzoin, and is also produced by the oxidation of hyduret of benzoyle, by the decomposition of hippuric acid, so that it often occurs in the urine of herbivora, and among the products of the oxidation of such bodies as fibrine, albumen, &c. Its formula is as follows, with those of its homologues:—

Benzoic acid.........	$C_{14}\,H_5\,O_3, HO$	=	$C_{14}\,H_6\,O_4$
Toluylic acid.........	$C_{16}\,H_7\,O_3, HO$	=	$C_{16}\,H_8\,O_4$
Xylitic acid?.........	$C_{18}\,H_9\,O_3, HO$	=	$C_{18}\,H_{10}\,O_4$
Cuminic acid.........	$C_{20}\,H_{11}\,O_3, HO$	=	$C_{20}\,H_{12}\,O_4$

The third acid is hardly known, but some of its derivatives are known, and are perfectly homologous with those of benzoic acid. Toluylic acid is connected with substances found in balsam of Tolu, and cuminic acid with those found in oil of cumine. These acids are all crystallized,

volatile, soluble in water and in alcohol, and approach in characters to resinous bodies.

2. In the next series are those compounds of which the type is hyduret of benzoyle. This is an oily liquid, found in the oil of bitter almonds with hydrocyanic acid. These substances, with others, are formed in the fermentation of amygdaline, a substance peculiar to bitter almonds. The hyduret when pure is $C_{14}\ H_6\ O_2 = C_{14}\ H_5\ O_2$, H. It absorbs 2 eqs. of oxygen from the air, and is soon converted into benzoic acid; $C_{14}\ H_6\ O_2 + O_2 = C_{14}\ H_6\ O_4$. It may be viewed as the hyduret of the radical benzoyle, $C_{14}\ H_5\ O_2$; and this radical, with 1 eq. of oxygen, forms dry benzoic acid, $C_{14}\ H_5\ O_2 + O = C_{14}\ H_5\ O_3$. At the same time the hydrogen is converted into water, which combines with the dry acid to form the crystals $C_{14}\ H_5\ O_2$, $H + O_2 - C_{14}\ H_5\ O_3$, HO. The oil of cumine, $C_{20}\ H_{12}\ O_2$, may be viewed as the hyduret of cumyle, C_{20}, $H_{11}\ O_2$, H, and is homologous with it. These hydurets may be regarded as the aldehydes of the acids they yield.

3. The next series may be that of the radicals, benzoyle, cumyle, &c. They are hardly at all known.

4. The next is that of the amides of the acids of series 1. Benzamide, toluylamide, cuminamide, &c. Benzamide is benzoyle + amide, or $C_{14}\ H_5\ O_2$, NH_2, and the others are analogous.

5. The next may be that of chloride of benzoyle, $C_{14}\ H_5\ O_2$, Cl.

6. The next, that of cyanide of benzoyle, $C_{14}\ H_5\ O_2$, Cy.

7. The next may be that of sulphuret of benzoyle, $C_{14}\ H_5\ O_2$, S. Many more might be added, but these will suffice to illustrate the compounds in which benzoyle, $C_{14}\ H_5\ O_2$, may be traced.

8. The next series contains products of decomposition of the acids of this series. When benzoic acid is heated with excess of lime, it is resolved into 2 eqs. of carbonic acid, containing all its oxygen, and a remarkable carbohydrogen, containing all the hydrogen, $C_{14}\ H_6\ O_4 + 2\ CaO = 2\ (CaO, CO_2) + C_{12}\ H_6$. This last is benzoyle, or hyduret of phenyle, $C_{12}\ H_5$, H. It is a somewhat fragrant liquid, which is found also in coal tar. Four homologous liquids are known, which are toluole, $C_{14}\ H_8$; xylole, $C_{16}\ H_{10}$; cumole, $C_{18}\ H_{12}$; and cymole, $C_{20}\ H_{14}$.

9. The next series is that of which the radical phenyle, $C_{12}\ H_5$, is the type. They are not known in the separate state, but enter into many compounds, the bodies of the last series being their hydurets. They have some analogy to the methylic radicals.

10. The next series is that of the hydrated oxides of the phenylic radicals. Hydrated oxide of phenyle, the type, $C_{12}\ H_5\ O,\ HO = C_{12}\ H_6\ O_2$, is found in coal tar, and often called carbolic acid. It much resembles creosote, and it is most probable that the compound next to it, $C_{14}\ H_8\ O_2 = C_{14}\ H_7\ O$, HO, is creosote itself.

11. We next come to the compounds of the phenylic radicals with amide, which, as in the case of the ethylic radicals, are volatile bases. The first of them is phenylamine or aniline, $C_{14}\ H_7\ N = C_{12}\ H_5,\ NH_2 = NH_2\ Ph$ ($Ph = C_{12}\ H_5$). It is an oily base, distinguished by the great tendency of its salts to crystallize. Its homologues are solid but fusible, and quite analogous to it. We have—

Phenylamine......	$C_{14}\ H_7\ N{=}NH_2,\ C_{12}\ H_5$	Aniline
Toluylamine.......	$C_{16}\ H_9\ N{=}NH_2,\ C_{14}\ H_7$	Toluidine
Xylamine	$C_{18}\ H_{11}\ N{=}NH_2,\ C_{16}\ H_9$	Xylidine
Cumylamine	$C_{20}\ H_{13}\ N{=}NH_2,\ C_{18}\ H_{11}$	Cumidine
Cymylamine	$C_{22}\ H_{15}\ N{=}NH_2,\ C_{12}\ H_{13}$	Cymidine

Aniline is obtained by heating indigo with potash, and is also found, with some of the others, in coal tar and animal oil, that is animal tar oil. In this oil, obtained by distilling bones, there is another homologous series of volatile bases, discovered by Dr Anderson, isomeric with these, but far more volatile. The first of them, picoline, is isomeric with aniline, lutidine with toluidine, &c.

12. There are no compounds which yield a greater number of substitution products than those we are here reviewing. In the first place, besides the amide bases above given, there are two other series, imide and nitryle bases, of which the types are diphenylamine, $NH\ Ph_2$, and triphenylamine, $N\ Ph_3$. These also have their homologues, and form two new series. Then aniline, by replacement of its own hydrogen by chlorine, bromine, &c., and nitrous acid, yields such compounds as chloraniline, dichloraniline, trichloraniline, bromaniline, dibromaniline, tribromaniline, nitraniline, dinitraniline, and others, in which 1, 2, or 3 eqs. of the hydrogen of the radical phenyle in aniline are replaced by the elements just mentioned. To take an example or two, we have—

Aniline..............................	$NH_3,\ C_{12}\ H_5$
Chloraniline	$NH_2,\ C_{12}\left.\begin{matrix}H_4\\Cl\end{matrix}\right\}$
Dibromaniline..............	$NH_2,\ C_{12}\left.\begin{matrix}H_3\\Br_2\end{matrix}\right\}$
Nitraniline	$NH_2,\ C_{12}\left.\begin{matrix}H_4\\NO_4\end{matrix}\right\}$

Most of these are basic and crystallize well. The homologues of aniline yield similar products, so that each is the commencement of a series.

13. Besides this, the hyduret of phenyle, or benzole and its homologues, also yield similar substitution products with chlorine, bromine, and nitrous acid. Thus we have, with others,

Benzole	$H,\ C_{12}\ H_5$
Nitrobenzole	$H,\ C_{12}\left.\begin{matrix}H_4\\NO_4\end{matrix}\right\}$
Dinitrobenzole	$H,\ C_{12}\left.\begin{matrix}H_3\\NO_4\end{matrix}\right\}$
Chlorobenzole.	$H,\ C_{12}\left.\begin{matrix}H_4\\Cl\end{matrix}\right\}$
Bromobenzole............	$H,\ C_{12}\left.\begin{matrix}H_4\\Br\end{matrix}\right\}$

These compounds, each of which represents or typifies a new homologous series, give rise also to various reactions, producing other compounds. But even without this, we have here another large group of homologous series.

14. Another considerable group consists of the various substitution products derived from benzoic acid itself. For example, there is nitrobenzoic acid. Benzoic acid, $C_{14}\ H_6\ O_4$, or rather $C_{14}\ H_5\ O_3$, HO, has one of the 5 eqs. of hydrogen in the anhydrous acid replaced by nitrous acid, and gives the new acid, $C_{14}\left.\begin{matrix}H\\NO_4\end{matrix}\right\}O_3$, HO. Then there is bromobenzoic acid, as well as others, each of which typifies a series.

Here also might be added two other series, namely, that of benzoglycolic acid and that of its amide, which is hippuric acid; but these have been already noticed among the series connected with the ethylic radicals. These two series, in fact, serve to connect the benzoic with the ethylic group of homologous series.

Hyduret of benzoyle gives rise to a very large number of new compounds, by the various reactions it undergoes with different substances, such as bases, ammonia, sulphuret of ammonium, &c. &c. Among these new products are several remarkable bases, such as amarine, sophine, and picrine. It is not known that these belong to homologous series, but it is probable.

Allied to the benzoic group are some others, of which but few members are yet known.

Thus oil of anise and oil of estragon yield when oxidized by nitric acid an acid, anisic acid, $C_{16}\ H_8\ O_6$. Oil of Gaultheria procumbens contains, in union with oxide of methyle, an acid called salicylic acid, because it can be formed artificially from salicine, the bitter principle of willow-bark. Sali-

cylic acid is $C_{14} H_6 O_6$, and is therefore homologous with anisic acid.

There are also the hydurets of salicyle and of anisyle, which bear the same relation to these two acids as hyduret of benzoyle does to benzoic acid. Hyduret of salicyle is the oil of spiræa, and is isomeric with benzoic acid, $C_{14} H_5 O_3, HO = C_{14} H_5 O_4, H$.

There are many interesting compounds connected with salicylic acid and hyduret of salicyle, and these probably belong to homologous series, as the two bodies themselves do.

Again there is oil of cinnamon, which yields hyduret of cinnamyle, $C_{18} H_8 O_2, H$, and this by oxidation becomes cinnamic acid, $C_{18} H_7 O_3, HO = C_{18} H_8 O_4$. This acid is very analogous to benzoic and salicylic acids. Heated with lime, it yields the carbohydrogen $C_{16} H_8$, analogous to benzole or hyduret of phenyle, along with 2 eqs. of carbonic acid. It is probable that these compounds are each members of new homologous series, and that these series are nearly allied to those of the benzoic group.

Having thus very briefly indicated the existence and nature of a large number of homologous series, we must shortly notice those compounds which cannot as yet be reduced to such series, although we have every reason to expect that in time they may be so classified.

These we must notice very briefly, but as they form certain well-marked natural groups, it will be possible, in small space, to convey a general notion of their nature and properties.

1. *Organic Acids.*

These are numerous, and it is but in very few cases that we know, as yet, anything about their constitution, that is, about the radicals they contain. We have seen that something is known, in that respect, of formic and acetic acids, of the oily acids homologous with these, of oxalic acid, and of benzoic acid and its congeners.
